For two thousand years the young medical graduate has subscribed to the oath of Hippocrates, which has been kept with high fidelity by the great body of medical practitioners. Comparatively few have deserted to quackery, very few have become criminals, many have become the victims of fortuitous circumstances, social maladjustment, personal ineptitude or denial of opportunity by special social or political combinations without deserting ethical standards.

Comparative ratings place the followers of Hippocrates in the highest ranking of all professions. One hundred thousand of the 150,000 physicians in the United States are members of organized medicine as represented by the American Medical Association. Prompted by a desire for the society of their fellows, by a desire for group protection, by a desire to follow the currents of scientific thought, by a growing appreciation of the importance of political organization, physicians are joining their county medical societies in increasing numbers.

The physicians of the United States have given the people of the United States the best medical service in the world. A continuing fall in morbidity and mortality statistics refutes the arguments of those who accuse the medical profession of inefficiency. The accumulating results of preventive medicine, of immunizations, of sanitation, of protection of the public health, are radically changing the scientific fields of medical practice, while easy and rapid communication is changing its geography. Familiar acute diseases are being replaced by chronic illnesses which are incident to the physical degeneration of the increasing number of people who live beyond sixty years.

Institutional treatment is replacing home treatment. The annual report of the New York hospitals commissioner shows that at least one half of the hospital population, which is 10 per cent of the entire population of the city, relies on the medical service of municipal institutions, and these institutions are manned by physicians who work for the pay of experience even unto the sixty-fifth year of their age so that they may learn how to give better care to the procession of new patients who constantly crowd these public facilities. An addition of the free care of dispensary and below-cost ward patients of the voluntary hospitals still further lessens the material attractiveness of medical practice in a large city.

Tax supported hospitals are the only hospitals that are free from the imminence of financial disaster. The voluntary hospitals are wallowing in the depths of deficits while speculating on the date when they will be forced to lose their identity and beg for tax support. Annual drives for maintenance are becoming more difficult and disheartening to generous people, who are endlessly pestered by campaign managers. How long can the major operation be deferred which will result

Read before the Thirty Second Annual Congress on Medical Education, Medical Licensure and Hospitals, Chicago, Feb. 18, 1936.

11 the closing of some hospitals and a realignment of hospital service in zones designed to serve definite units of population? How long will it be before every resident of a hospital zone will carry an identification tag which will entitle him to medical care in a municipal hospital? How long will it be before physicians who work in tax supported hospitals will be paid for their work? How seriously will such an evolution affect the field of private practice? These are not fantastic questions. In all fairness they should be earnestly studied by the teachers of young people who are planning to study medicine, so that they may be competent to discuss these important economic problems with those whose careers are surely their responsibility.

Why are more and more young people trying to enter the practice of medicine when it is well known that there are now less than 800 persons to one physician and that half as many physicians die as are licensed every year? If the sources of inspiration of these young people can be discovered those whose urge originates outside of idealism or outside of the desire for real scientific study should be firmly discouraged.

Once upon a time a physician, an engineer and a politician were in earnest discussion concerning the antiquity of their professions. "Medicine is the oldest of all," said the physician. "It is recorded in holy writ that God removed a rib from Adam and created Eve. That surely was the first surgical operation." "But earlier than that," said the engineer, "God created order out of chaos—an engineering problem." "Well," said the politician, "my profession antedates both of yours. May I ask you who created chaos?"

One can hardly be accused of great disrespect if at this time in our history "chaos" looms large in our daily vocabulary. The uncertainty concerning the future of medical practice, the possibility of changes affecting all our social objectives, changes in standards of living, destruction of investment values, the shattering of traditional ideals, makes one feel that the physician of the future may turn himself into a composite picture of physician and politician if he shall have any measure of success in preserving any part of the high quality of present-day medical service or lead it to greater or higher planes.

The young physician at 27 or 28 or 30 years of age is handicapped by a lack of any fundamental knowledge or teaching of economics, and I have reason to believe that he has not been well prepared to take his place in society by instruction in the practicalities of medical problems. He has been seven or eight years in college, too busy to have business contacts outside the classroom and too concerned with abstract theory to have had time for the study of human beings as members of society. Teachers are too infrequently interested in the student's personality. Students report infrequent personal contacts, no social relations, no social inspiration. They say that their teachers assume academic detachments, platform manners or exhibition of knowledge designed to invite consultations. Too often the teacher is so absorbed in his specialty that he does not care for general contacts. He takes no interest in his county medical society, where he would meet the general run of physicians. He fails to function as a citizen. If these criticisms are correct or justified, he is unfit to develop practically useful physicians or to inspire his students with high social objectives. The exigencies of the times demand that he prepare himself for the teaching of practical economics and for the prepa-

ration of the student for his place in society. He should, above all other physicians, become active in medical organizations so that he may have first hand knowledge of present trends and present needs. The young physician should be taught something about public health, preventive medicine and especially practical medicine for the benefit of real patients.

At the December examination for internships at the Morrisania City Hospital, 190 candidates presented themselves. They represented forty-two medical schools. Forty-two of these applicants were rated by their schools at 90 per cent or above, several of them being decorated with the golden keys which marked them as scholars of distinction. Only five of these highly rated men were successful in winning places among the sixteen who were finally chosen for internships. The examining committees were instructed to ask only practical questions, in order to test the reasoning powers rather than the memory of the candidates. Sample questions are here quoted along with the appraisals of the examiners. "I asked the following question," said one examiner. "You are called to see a man 30 years old who has an inguinal hernia which is strangulated. Attempts at reduction do not avail. After examination you find that the patient has severe diabetes with impending acidosis. How would you treat this patient?" Most of the candidates answered this question by a discussion of the treatment of diabetes with acidosis, stressing the use of insulin, the dosage, and so on. Very few candidates saw the problem as a whole, nor did most of them appreciate the need for imperative surgery as a concomitant of the medical treatment. I gathered the impression that the candidates were well informed concerning the treatment of the disease diabetes (especially as an academic exercise) but that they were not trained to see the situation in its entirety as it presents itself to the physician."

Another examiner writes

Relative to our recent discussion about intern examinations and the peculiar lack of practical thought on the part of even the best of students, I call your attention to the type of questions asked by me. "1. You are called on an ambulance case and find a patient bleeding from the vagina actively. She is pregnant, near term and not in labor. What would you do?" The answers ranged from cesarean section through the entire gamut of theoretical methods. "2. You are called to treat a multipara who is in active labor, about three fingers dilated. A prolapsed cord is found not pulsating. Assume the baby dead. What would be your treatment?" Again the answers ran from version, craniotomy, embryotomy, to cesarean section. I have been asking this type of question for several years. There seems to be something wrong in the medical teaching in most of the schools. When I get a correct answer I can almost predict that the student comes from a certain school.

A surgeon asked "What are the commonest causes of rectal bleeding?" He writes

First I wanted to see how the student approached the subject, and second to ascertain whether he is trained to think of the most likely things that may cause the particular ailment. Of 100 candidates to whom this problem was presented the answers were such that after a while I could tell whether the student came from one or another type of school. One group enumerated the causes almost in exact order of occurrence, such as hemorrhoids, fissures, neoplastic growths and finally more remote factors such as ulcers in the upper part of the alimentary tract and various rarer conditions. Others began by saying cirrhosis of the liver, blood dyscrasias and other rare causal factors. A very few schools seem to train the young

mind to think along a smooth pathway and not to flounder into by-ways that lead him to think of rare rather than common etiologic factors

A urologist writes

May I state that almost all the students who appeared before our committee were, from a didactic standpoint, remarkably well prepared. I have never before encountered a group of young men whose scholarship attainments were manifestly of such high order. Consequently, it seemed to me that it might not be amiss to sound their reasoning powers. For instance, I asked several of them 'How would you conduct the case of a married man suffering from an acute gonorrheal infection?' I was not so much interested to hear of the injection of germicides but rather to determine their idea of the ethics involved, their tact in approaching such a difficult situation and their appreciation of the humanities. The gentlemen who attempted to answer my question were distinctly nonplussed. With the curriculums as complicated and time consuming as they are, it is perhaps difficult for a faculty to provide or find time for such instruction. The young medical man of today by and large, in my opinion, is distinctly disappointed when a patient, or the patient's complaint cannot be "classified." The personal element is minimized. The physician's responsibility to and for the patient is not sufficiently emphasized and a spirit of genuine sympathy for suffering is not inculcated as a fundamental principle.

As a result of this type of questioning, the representatives of nine schools won the first sixteen places: Bellevue five, Columbia two, Cornell one, Creighton one, Flower two, Jefferson 1, Long Island two, Rush one, Tufts one. The sixteen alternates came from six schools: Bellevue five, Columbia two, Flower four, Baylor two, Rush two, Boston one. It would seem to be a reasonable inference that these schools are trying to develop clinicians. It may also be of interest to note that none of these thirty-two candidates were personally known to the examiners.

At the Morrisania Hospital we became so impressed with the lack of the practical training among our forty interns and residents that we initiated some procedures during the past three years which were warmly welcomed by the interns, who are frequently suggesting other ways in which they may learn how to meet the actualities of medical practice. Every new intern is given a complete physical examination and is advised as to measures designed to correct physical defects. It seems strange to discover among these persons who have been eight years in college, serious visual defects which were seriously affecting their ability to work without undue fatigue, to find an advanced case of leukemia, and some others with tuberculous lungs. A review of college records of annual physical examinations shows no blood counts or roentgenograms of the chest. We instituted a course in ordinary nursing procedures, with demonstrations of bed making, bathing, enemas, mustard plasters, hypodermoclyses and so on. No intern is allowed to ride an ambulance until he has been instructed in practical first aid measures and is taught how to treat the ordinary emergencies which he may meet.

Frequent meetings are held to give interns opportunities to ask questions of the administrative staff, all of whom are cordially cooperative. As an outcome of their expressed desire for practical education and at their direct request, practical lectures are given on forty Wednesday afternoons during the year, which are attended by all interns who can be freed for an hour from their ward services. Questions are asked and both lecturers and interns report that the time is profitably spent. These lectures are not substitutes for the regular medical surgical, pathologic, x-ray and

ward conferences, at which the heads of every service are putting an emphasis on useful procedures and trying to make the intern self reliant in the exercise of his five senses and his powers of deductive reasoning. To promote this experience, every intern is also required to meet ambulatory patients in the outdoor clinics under the direction of members of the staff, who are trying to teach a practical application of medical knowledge which might be useful in the regular office experience of the ordinary practitioner.

We might all do well to follow the example of Sir William Osler in personal contacts with students and interns, his stimulating push toward a good impulse, which brought his school to so high a place. Thayer's paraphrase of Osler's advice to his students may be profitably remembered.

Observe, record, tabulate, communicate. Use your five senses. The art of the practice of medicine is to be learned only by experience, it is not an inheritance, it cannot be revealed. Learn to see, learn to hear, learn to feel, learn to smell and know that by practice alone you can become expert. Medicine is learned at the bedside and not in the class room. See and reason and compare and control. But see first. No two eyes see the same thing. No two mirrors give forth the same image. Let the word be your slave and not your master. Live in the ward.

We are aware that the only thing new about our program at the Morrisania Hospital is that our visiting and attending staff is functioning in it and that our interns are liking it. While we have been talking a great deal about preserving the social qualities of the old general practitioner, we must admit that a few schools have been quietly producing better general practitioners than we have ever known. The hospital may do something to promote sound practice, but the development of clinicians who will be valuable social agents must begin with the admitting committees at the colleges and continue vigilantly through every undergraduate year. Occasional lectures will have small value. The entire corps of teachers must be imbued with a keen appreciation of their own social responsibility and must transmit the spirit of it to their students. The faculties that do not teach practical medicine are perhaps in some degree responsible for the wave of machine shops which young physicians are setting up all over the country. Failing inspirational influence, the social objective of some young physicians seems to place material gain above service to the sick. They continue their education under the seductive eloquence of salesmen for machinery and drug houses and go deeply into debt, mortgaging their futures for several years of instalments, which must be retrieved from credulous patients, who are put through the whole show of unnecessary x-ray, fluoroscopic, electrocardiographic, lamp and mechanical tests with which the physician himself is only faintly acquainted. It is an amazing experience to walk into the office of a recent graduate and realize, by quick computation, that some one is backing an investment of from three to five thousand dollars or more in mechanical equipment. It is reasonable to fear that these young physicians are in danger of slipping into the mire of quackery, are sacrificing ideals to expediency, and are also creating an impression in the minds of patients that physicians who do not possess these elaborate instruments are consequently incompetent to make diagnoses or to advise up-to-date therapy.

Is this unsocial conduct merely a phase of practice that will destroy itself by lowering popular respect for these instruments through their indiscriminate and unskilled use? Will it need the disapproval of medical organizations? Will it need public education? It seems obvious that machines and gadgets must be subordinated to intelligence and a revival of common sense. Censorship or ostracism will not cure a disease that is grown on weak characters and fostered by ignorance or a myopic conformity to local custom. Many of us become virtuous when we grow too old to have personal ambitions and forget that human nature seldom scorns acquisitiveness in the presence of opportunity. While employing all the progressive results of scientific research, let us not forget the sound lessons of the past and let us try to encourage our highly educated young physicians to take the places of leadership in community life for which they are potentially qualified. The young physician's social objective may not point higher than making an honest living, but if this aspiration is based on respect for a high quality of service the health of our people will be in safe hands.

The development of this objective lies in the hands of those who are privileged to carry on the teaching of advanced students.

1 They must educate themselves by active membership in medical organizations

2 They must select fewer medical students with severer scrutiny of character qualifications

3 They must carry on intensive teaching of clinical medicine

4 They must promote inspirational preceptorial contacts between teacher and pupil

5 They must try to develop medical citizens whose education will entitle them to leadership in their communities

It is my personal belief that raising the level of the practical education of all young physicians and attempting to impress them with their civic responsibility will strengthen their ability to handle all their social and economic problems.

300 East Tremont Avenue

Basophilic Adenoma—The syndrome associated with basophilic adenoma of the pituitary as described recently by Cushing was characterized by (1) a rapidly acquired, peculiarly disposed, and usually painful adiposity confined to the face, neck, and trunk, the extremities being spared, (2) a tendency to become round shouldered even to the point of a measurable loss of height associated with lumbospondyl pains, (3) a sexual dystrophy shown by early amenorrhea in females and ultimate functional impotence in the male, (4) an alteration in normal hirsuties shown by a tendency to hypertrichosis of face and trunk in females and adolescent males, and possibly the reverse in the adult males, (5) a dusky or plethoric appearance of the skin with purplish linear atrophicæ particularly marked on the abdomen, (6) vascular hypertension, (7) a tendency to erythremia, (8) variable backaches, abdominal pains, fatigability, and ultimate extreme weakness. The features less often noticed were xeroderma, purpura like ecchymoses, aching pains in the eyes associated with exophthalmos, transient diplopia, suggestive papilledema, dimness of vision, subretinal exudate and retinal hemorrhage, extreme dryness of the skin, pulmonary infections, albuminuria, insomnia, increase of non-protein nitrogen and cholesterol in the blood and polymorphonuclear leukocytosis.—Brumgartner, Leona. Pituitary Basophilism and Hypertension. *J. Biol. & Med.* 7:327 (March) 1935.

RECURRENCE OF INOCULATION MALARIA

MAGNUS C. PETERSEN, M.D.
Assistant Superintendent, St. Peter State Hospital
ST. PETER, MINN.

It is generally thought that tertian malaria transmitted by direct blood inoculation is easily cured by quinine. According to James,¹ "clinically there is a striking difference between the two classes in that true (long interval) relapses and recurrences are not observed (so far as we can ascertain) in inoculated cases, while they occur in 50 per cent of mosquito infected cases." He adds that blood inoculated cases are cured by a single short course of quinine. Yorke² concurs in this view, saying "it is an established fact that two or three doses of quinine almost invariably suffice definitely to cure the inoculated case." Wagner-Jauregg³ relates that in Vienna, where more than 6,000 patients have been treated, no case of recidivation has been noted. He considers 5 Gm. of quinine, given in the course of a week, sufficient to cure the disease.

Although few in number, recurrences have been recorded. Redlich⁴ observed one following the administration of 3 Gm. of quinine. Grant and Silverston⁵ noted two cases after 6 and 4 Gm. respectively. The first occurred forty-two and the second eighteen days after termination. Serafinow⁶ had one recurrence in a series of forty-two cases treated. Kulagin and Petrasov⁷ refer to a case reported by Luntz in which malaria was present in the blood for more than three years, and they add one of their own.

Between August 1927 and February 1935 a total of 261 patients were treated with inoculation (tertian) malaria in the St. Peter State Hospital. Usually the chills terminated promptly when quinine was administered, but the plasmodium often remained in the circulation long afterward.

In fourteen cases the parasite was found in thin smears from six to 150 weeks after the fever subsided. These patients had received from 5.3 to 97 Gm. of quinine sulfate orally. The average amount was 44 Gm. With one exception these recidivations occurred between the seventieth and the one hundred and sixtieth direct passage of the strain.

Malarial parasites remained in the blood of one of these patients for six weeks, after which they disappeared. A smear made in a routine way 150 weeks after termination was positive, but several subsequent smears were negative. No clinical symptoms were noted at the time. Beginning in the one hundred and eightieth week, the patient showed symptoms strongly suggestive of malaria, but the plasmodium could not be found in the blood.

Nine other patients had definite recurrence of the disease during which the parasite was found in the circulation. Relapses also were observed in two patients treated elsewhere. These eleven cases are reported.

REPORT OF CASES

CASE 1—G A O, a white man, aged 56, a native of Sweden, was inoculated (twenty-third passage) Nov 5, 1928. Between the 10th and the 21st of November he had seven irregular rises in temperature. The fever terminated spontaneously on the latter date. He was given 1 Gm of quinine sulfate daily from November 28 until December 3, inclusive.

No untoward symptoms were noted until ninety-three weeks later, when on Sept 17, 1930 he complained of abdominal distress. The temperature, which was elevated every forenoon, did not return to normal until October 29. Although 1 Gm of quinine sulfate was given daily for a period of forty-two days, blood smears remained positive for malaria until October 22. After that they were negative. The patient developed pneumonia and died on Feb 7, 1931. No microscopic examination was made of the blood at the time.

CASE 2—M C, a white woman, aged 30, a native of Czechoslovakia, was inoculated (sixty-eighth passage) Feb 13, 1931. After five chills, the first of which occurred February 24 and the last March 6, the fever terminated spontaneously. As malarial parasites persisted in the circulation, quinine medication was commenced March 13. From then until October 1 she was given 1 Gm of quinine sulfate daily. On the latter date the dosage was increased to 2 Gm. This was continued until November 14 when it was decreased to 1 Gm. The medication was discontinued November 17. During this time a total of 293 Gm was administered. The temperature curve began to show irregularities May 4. There were elevations every day or every other day, with occasional sharp peaks reaching a maximum of 102 F. Blood smears remained positive for malaria until September 2. In May 1935 the patient showed symptoms strongly suggestive of malaria, but the plasmodium could not be found in the blood.

CASE 3—M B, a white man, aged 50, a native of Minnesota, was inoculated (eightieth passage) Sept 11, 1931. The course was terminated after nine chills, the first of which occurred September 21 and the last October 1. Between the latter date and December 8 the patient was given 1 Gm of quinine sulfate daily. Blood smears remained positive for malaria, however, and the patient had severe chills November 30 and December 1. The temperature remained normal from then until December 8 when another severe chill occurred. The quinine was then increased to 2.65 Gm daily. The temperature remained normal until the patient left the hospital Dec 22, 1931. Unconfirmed reports indicate that there were recurrences later, but this could not be verified. Although 107 Gm of quinine was administered, malaria was present in the blood Dec 17, 1931, when the last examination was made.

CASE 4—A H, a white man, aged 28, a native of Minnesota, was inoculated (seventy-eighth passage) Aug 8, 1931. The first of ten paroxysms occurred on the 14th and the last on the 29th of August. Between the latter date and September 10 a total of 16 Gm of quinine sulfate was given. The patient remained well for fifty-eight weeks until Oct 8, 1932 when he commenced to have an elevation in temperature every other day. Malarial parasites were found in the blood. A total of 13 Gm of quinine sulfate was given during a period of twenty days. The temperature remained normal after October 7 but the plasmodium persisted in the circulation until November 10. A blood smear made in a routine way Sept 29, 1934 was negative. The patient died Jan 2, 1935. No examination was made of the blood at the time as the symptoms were not suggestive of malaria.

CASE 5—F A E, a white man, aged 46, a native of Minnesota, was inoculated (one hundred and fifth passage) April 25, 1933. The first of eleven chills occurred on the 10th and the last on the 27th of May. From May 26 until June 20 inclusive, 1 Gm of quinine sulfate was given daily. No malarial parasites were found in the blood June 16. The patient remained well for thirty weeks, until Jan 16, 1934, when he commenced to have fever and chills. The plasmodium was found in the blood January 22. Between the latter date and April 3 the patient was given 41 Gm of quinine sulfate. The temperature did not become normal until February 23 when he was given 0.75 Gm of neoarsphenamine intravenously. During this period the patient had sixteen distinct chills. Malarial parasites were present in the blood up until and including February 16 but

were not found later. A blood smear made in a routine way Sept 29, 1934, was suggestive of malaria, but several subsequent smears were negative. The patient was transferred to another hospital May 31, 1935.

CASE 6—G H P, a white man, aged 43, a native of Minnesota, was inoculated (twentieth passage) Aug 17, 1928. The first of eight chills occurred August 24 and the last September 5. During the following seventeen days, 1 Gm of quinine sulfate was given daily.

The patient remained well for 146 weeks, until June 29, 1931, when he suffered a heat stroke. The temperature returned to normal in the course of seven days. No microscopic examination was made of the blood at the time.

No further symptoms were noted until 311 weeks after termination, when on Sept 1, 1934, typical symptoms of malaria developed and the plasmodium was found in the blood. Between the 2d and the 28th of September he was given 22 Gm of quinine sulfate. Although the temperature became normal September 9, blood smears remained positive until September 29. On account of the suggested periodicity, the temperature was observed during April 1935. It was slightly elevated every forenoon, but blood smears were persistently negative for malaria.

CASE 7—M N, a white man, aged 38, a native of Finland, was inoculated (fifth passage) Oct 11, 1927. The first of twelve chills occurred October 20, the last November 10. During the following twelve days, 1 Gm of quinine was given daily. No microscopic examination was made of the blood after the fever subsided. A blood smear made in a routine way Sept 9, 1934, was very suggestive of malaria, but several subsequent smears were negative. There were no symptoms suggestive of malaria at the time.

The patient remained well for 374 weeks after termination, until Jan 21, 1935, when he commenced to have daily elevations in temperature. Examination showed pleural effusion on the right side. Roentgen examination of the chest made during a general survey about two months previously showed no abnormalities. Malaria was found in the blood, February 6. Although the temperature decreased when quinine was given, it did not return to normal. In June the fever became more marked and the patient died, June 24, 1935.

CASE 8—B S, a white man, aged 46, a native of Germany, was inoculated (sixth passage) Oct 29, 1927. The first of ten chills occurred on the 6th and the last on the 21st of November. He was then given 53 Gm of quinine sulfate within a period of six days.

The patient remained well for 382 weeks, until March 27, 1935 when he commenced to have chills and fever. At first the plasmodium could not be found in the blood, but after the patient had several chills the smears became positive. He was given 14 Gm of quinine sulfate during the first week in April and 73 Gm during the second. The temperature, which had returned almost to normal, rose again when the quinine was discontinued. Beginning April 25, 0.1 Gm of atabrine was given three times a day over a period of seven days. This controlled the fever temporarily, but there was a recurrence of chills when it was discontinued. Between the 4th and the 8th of May, 12 Gm of quinine sulfate was given. From May 11 until July 23 2 Gm was given daily. On the latter date quinine hydrochloride was substituted. This was reduced to 1 Gm daily August 10 and discontinued September 14. Between July 25 and September 11 he also received fourteen intravenous injections of 0.45 Gm of neoarsphenamine. Although the temperature remained normal most of the time after the neoarsphenamine was commenced, it would increase if the interval between injections was more than four days. There were occasional sharp elevations up until October 4.

The patient received a total of 181 Gm of quinine sulfate, 71 Gm of quinine hydrochloride, 21 Gm of atabrine and 63 Gm of neoarsphenamine.

CASE 9—M P, a Negress, aged 20, a native of Alabama, was inoculated (eighteenth passage) Dec 3, 1934. The first of three prolonged paroxysms occurred on the 11th and the last on the 17th of December. Following this the temperature remained normal until December 26 when it commenced to show irregularities. Slight increases were noted every day or every other day. Broken by occasional afebrile periods, this continued during the winter. From December 15 until

January 8, 1 Gm of quinine sulfate was given daily. On the latter date the dosage was doubled. The amount was again reduced to 1 Gm daily, February 21. This was continued until April 3, when it was increased to 3 Gm daily. Blood smears were positive January 7 but negative January 16 and February 21. A positive smear was again obtained April 3. March 31 the temperature became markedly elevated. Examination showed pleural effusion. The patient died, April 6, 1935. The total amount of quinine administered was 124 Gm.

CASE 10—E C M, a white man, aged 49, a native of Minnesota was inoculated in the Ancker Hospital St Paul, Aug 5, 1933. The temperature showed daily elevations between the 7th and the 15th of August inclusive. On the latter date 1 Gm of quinine was given intravenously. This was repeated the following day. He was then given 2 Gm orally for three days and 1 Gm for four days. The temperature became normal on the 15th.

The patient was transferred to the St Peter State Hospital, Aug 30, 1933. September 5 he had another paroxysm lasting four days. He had chills again on the 9th and the 10th. The temperature remained normal after the 11th. Malarial parasites were found in the blood, September 7. The patient died, Sept 13, 1933.

CASE 11—J J E, a white man, aged 50, a native of Minnesota, a patient of Drs Hammes and Kamman of St Paul, was inoculated May 7, 1935. The chills, which commenced on the 11th, were terminated on the 21st of May. Between then and July 12 he was given 80 Gm of quinine hydrochloride. In spite of that, chills occurred on the 7th, 17th, 28th and 30th of June and again on the 9th and 10th of July.

The patient was admitted to the St Peter State Hospital, July 12, 1935. Between the 13th and the 16th of July he was given 365 Gm of quinine sulfate orally and 0.45 Gm of neoarsphenamine intravenously. There were recurrences of chills on the 15th, 18th and 19th of July. Commencing July 16, 0.1 Gm of atabrine was given three times a day for seven days. The temperature became normal on the 20th but rose sharply on the 23d and again on the 28th. The latter elevation was prolonged, lasting until July 31. Beginning on this date, 13 Gm of quinine sulfate was given daily until August 13, when the amount was reduced to 1 Gm. The same day he was given 0.45 Gm of neoarsphenamine intravenously. As the patient again had chills on the 18th, 19th and 20th of August, the amount of quinine was doubled on the latter date and 0.45 Gm of neoarsphenamine was given intravenously every fourth day. Since then the temperature has remained below 100 F except on August 27, when it rose to 100.4 F. The amount of quinine was reduced to 1 Gm daily October 23 and was discontinued November 4. Malarial parasites were found in the blood July 15 but have not been found since. A total of 80 Gm of quinine hydrochloride, 100 Gm of quinine sulfate, 21 Gm of atabrine and 765 Gm of neoarsphenamine was administered.

COMMENT

Four apparently unrelated strains were involved in this series of recurrences. One strain was used for inoculations in the first eight cases, while a different strain was used in each of the last three cases. As it could not be ascertained how often the strains had been transmitted previously, the numbers refer to the passages undergone in our hands.

During this period only three cases of noninoculation malaria were observed in the hospital. A definite history of previous attacks was obtained in each case. Since malaria is not endemic in Minnesota and the patients were under constant observation in hospitals, reinfection is not probable.

There is a suggested periodicity in these recurrences. The time in one case was thirty weeks and in five cases a multiple of from twenty-nine to thirty-one weeks. A similar time relation was noted in several cases of suspected recurrence in which the plasmodium could not be found in the blood.

Frequently it was necessary to make a number of smears before the parasite could be demonstrated. The

temperature curve was more irregular during the recurrence than it was in the initial attack. At times it bore little or no resemblance to that generally described in textbooks.

A review of all the cases treated here convinces us that several recurrences were not recognized as such. The death of one patient, several months after leaving the hospital, undoubtedly was caused by malaria. The symptoms, later described by relatives, were typical of the disease.

These observations support the contention of Martini⁸ that inoculation malaria does not differ from that transmitted by the mosquito. We believe that a systematic search for the plasmodium in all malaria treated individuals having fever from any cause will reveal a number of unsuspected recurrences. Furthermore, the possibility that recidivation of inoculation malaria may be a factor in the spread of the disease deserves serious consideration.

EXPERIMENTAL THERAPY IN COCCIDIOIDAL GRANULOMA

HAROLD C SOX, MD

AND

ERNEST C DICKSON, MD

SAN FRANCISCO

In the therapy of coccidioidal granuloma numerous agents have been suggested since the first case was described by Rixford¹ in 1894. He used potassium arsenite, potassium iodide and yellow mercurous iodide internally and iodine, bromine, phenol, methyl violet, turpentine and mercury bichloride locally, without success. Subsequent writers have run the gamut of chemical, physical and immunologic agents. Montgomery and Ormsby² recommended general supportive measures as in the therapy of tuberculosis. Brown,³ Brown and Cummins⁴ and Burgess⁵ have suggested the use of iodides, and Cooke⁶ has suggested their use in conjunction with arsphenamine.

Antimony in the form of antimony and potassium tartrate has been used by a number of investigators. Guy and Jacob⁷ used it in conjunction with x-rays with apparent success but were unable to carry out animal experiments owing to the peritonitis developing from the injection of antimony and potassium tartrate, an experience which we can verify. Tomlinson and Bancroft⁸ used it in conjunction with x-rays, with an apparent cure. Childrey⁹ used antimony and potassium tartrate with potassium iodide without success. Chipman and Templeton¹⁰ used it in conjunction with

potassium iodide, aqueous solution of iodine, colloidal copper, typhoid vaccine and gentian violet without success. Jacobson¹¹ has discarded antimony and potassium tartrate in favor of colloidal copper and a vaccine prepared from cultures, together with carbon dioxide snow and x-rays locally, and with supportive therapy, reporting quite favorable results. Jaffe¹² also has used colloidal copper in conjunction with bismuth potassium tartrate and reported some improvement. Sorsky and Nixon,¹³ after a trial of antimony and potassium tar-

reached the ultimate cure but rather one of hope that the results will be as good subsequently as shown at the time of the report.

The purpose of this investigation is to attempt, by animal experimentation, to evaluate the various types of drug therapy suggested for the treatment of coccidioid granuloma.

Guinea-pigs were weighed and given the selected therapeutic agent for from five to ten days before inoculation. They were then inoculated with 0.1 cc of a suspension of coccidioides culture into the testicle and the treatment was continued daily thereafter. The culture was the most virulent of the Stanford collection (No. 10), having a twenty day virulence by intraperitoneal inoculation as tested three months prior to the experiment. It had been subcultured twice in the interval. The same strain was used throughout the experiment and no animal failed to develop the disease. From seven to ten day surface cultures on Sabouraud's medium were washed with physiologic solution of sodium chloride into impules and shaken with glass beads, in order to obtain a uniform suspension, and were then inspected microscopically to insure that fragmentation was complete.

The drugs were given intraperitoneally in estimated effective sublethal doses, with the exception of thymol, which was given by gavage because of its insolubility in water, and the vaccine, which was given subcutaneously. Table 1 shows the drugs used, their dosage, the number of animals and the length of life after inoculation.

Copper sulfate and antimony and potassium tartrate were found to be so irritating that several guinea-pigs were lost prior to inoculation before the optimal dose could be determined. The dosage was constant except in the case of thymol, in which the first and third pigs were given 60 mg per kilogram and the remainder 125 mg, with little difference in the results obtained. Colloidal copper was given three times a week, the total weekly dose being the same as the human dose per kilogram.

The vaccine was prepared by growing the organism in a synthetic medium introduced by Stewart and Meyer²² for isolating coccidioides from soil. Its com-

TABLE 1—Length of Life After Inoculation with Various Drugs

trate, methyl violet, gentian violet, potassium iodide, colloidal copper and "Bismoid" internally, with gentian violet and saturated solution of iodine in 5 per cent potassium iodide locally, have concluded that bismuth, copper and gentian violet internally warrant further clinical trial, and that gentian violet irrigations locally give satisfactory results in some cases.

Cummins and Sanders¹⁴ tried crystal violet without success and carried out a few animal experiments without definite results. Pulford and Larson¹⁵ report a case in which they used potassium iodide, potassium arsenite, a vaccine, colloidal lead, colloidal copper, high voltage therapy and gentian violet without success. Montgomery and Morrow¹⁶ tried x-rays without success, but Zeisler¹⁷ obtained some improvement but not a cure with x-rays. Hammack and Lacey¹⁸ amputated an infected extremity and report a cure, and Imerman¹⁹ excised a lesion with the actual cautery.

Myers²⁰ found thymol, carvacrol, its isomer, and the volatile oils of mustard, cinnamon and clove active fungicides, particularly for yeasts. Thymol was also active against actinomyces. Stockton²¹ found, in vitro, that 0.5 per cent concentration of thymol was effective in inhibiting the growth of coccidioides cultures, and he gave thymol to a patient in doses up to 2 Gm daily until 21 Gm was given in a ten day period without definite beneficial results. He found that the average daily excretion of thymol was 55 per cent of the daily dose but that it was quite variable, possibly owing to the variability in absorption.

In none of the articles reviewed does one receive the impression that the investigator feels that he has

position is as given in table 2. After thirty days' growth the culture was centrifuged, washed with physiologic solution of sodium chloride, moistened with salt solution, ground for forty-eight hours in a ball mill, filtered through a Seitz filter and tested for sterility by culture and inoculation. It was then given subcutaneously for an average of seventeen daily doses prior to inoculation. No vaccine was given after inoculation in the hope of demonstrating the development of some immunity or increased resistance to invasion.

The experiment was begun with no preconception as to the efficacy of any one drug but with the hope that some valuable data might be accumulated in a general survey of all the suggested therapeutic agents.

The accompanying chart strikingly summarizes the results obtained

The first guinea-pig that was treated with thymol was killed sixty-five days after inoculation, although in good health, in order to see whether a cure had been effected, but a well walled off lesion was discovered. Subsequent studies were concentrated more on this drug, with a result that all the experimental animals were found to live longer than the controls, the only drug in which this result occurred

Results of experiment

During the course of the animal experimentation, a patient entered Stanford Clinic and Lane Hospital with coccidioidal granuloma and was made available for study

REPORT OF CASE

A F, an Italian dairyman, complained of a boil on the neck of three months' duration

The family history was not significant

The patient had been in the United States for nine years near Fresno in the San Joaquin Valley

Nine months previously he had had chills and fever, which subsided in three weeks. Six months previously pain developed in the neck in the region of the seventh cervical vertebra, radiating down the left arm. The left arm gradually became weaker until he was unable to use it.

Five months before entry a swelling developed on the left side of the neck, gradually increasing in size, without pain, but with some limitation of motion of the neck.

Two months prior the abscess was opened by a local physician, with persistent drainage thereafter. The pain in the arm was somewhat relieved but the weakness persisted.

He lost 60 pounds (27 Kg) in nine months.

On physical examination the patient was well developed and fairly well nourished. There was a diffuse swelling and induration to the left side of the neck posteriorly, with a draining sinus opening from which exuded yellowish white purulent material containing the typical spherules of coccidioides, which gave positive results on culture and animal inoculation.

There was weakness of the left arm but no atrophy.

Results of the laboratory examination were: red blood cells, 5,000,000, hemoglobin, 90 per cent (Sahli), white blood cells 5,000, 81 per cent polymorphonuclear leukocytes and 1 per cent eosinophils. The blood Wassermann reaction was negative, and the urine was normal.

Röntgen examination showed destruction of the fifth sixth and seventh cervical vertebrae, with a large communicating sinus tract demonstrated after injection with potassium iodide solution.

Print fibrous fuzzy densities in the midlower portions of both lung fields were interpreted as evidence of lung involvement.

On entry potassium iodide was given in gradually increasing dosage until the patient was receiving 20 Gm daily with no evidence of improvement and continued loss of weight. Twenty-one days after entry thymol therapy was instituted. The sinus was washed out daily with dilute tincture of green soap and then 3 1/4 per cent thymol in olive oil was instilled through a catheter introduced to the bottom of the sinus. From that time no organisms could be isolated from the pus and there was a definite improvement in the appearance of the lesion. When a stronger solution (50 per cent) was used there was some pain referred down the arm.

At the time the irrigations were started, thymol was given by mouth starting with 1 Gm and gradually increasing to 6 Gm daily until a total of 104 Gm had been given in twenty-four days. The thymol was dissolved in olive oil in 50 per cent concentration and placed in capsules, which were administered during the meal in order to promote absorption and minimize gastric irritation. While the urine had a strong odor of thymol, no evidence of kidney damage could be discerned at this dosage. The loss of weight stopped after thymol was begun and the patient felt subjectively improved. The only unfavorable effect noted was a slight abdominal distress when the larger doses were taken, which persisted for about twenty minutes.

Owing to lack of funds, longer observation was not possible and the patient went to another part of the state, where information was no longer available.

SUMMARY

In a general survey of the agents used in the treatment of coccidioidal granuloma, eleven drugs and a vaccine were tested in the experimental animal, of which only thymol was found to give any definite favorable result.

In applying thymol in human cases, a dose of 6 Gm daily is well tolerated.

The local and systemic application of thymol in human coccidioidal granuloma was followed by encouraging results, and further application and study of thymol in this disease is indicated.

Clinical Notes, Suggestions and New Instruments

GAS INFECTION AFTER HYPODERMOCLYSIS

JOSEPH TENOPYR M.D. AND B. J. P. SHAFIROFF M.D.,
BROOKLYN

In 1933 Junghanns¹ analyzed more than sixty cases of gas gangrene that followed hypodermic medication of all types. To this report he added a single case of his own. This literature was made available to him after the plea by Anschütz in 1926 at the German Surgical Congress for reports and investigatory attempts at localizing the cause of this dangerous sequela to hypodermic medication. It is interesting to note that all possible factors involved in the giving of a hypodermic injection have been studied bacteriologically, yet rarely has the organism been recovered from the carrier agent. The wounds in all cases, however, have yielded the gas organism. Attempts to trace the gas bacillus to the hands of the administrator (nurse or doctor), the skin of the patient, the needles, the solution, the method of sterilization and any other conceivable source has usually been unsuccessful. In Junghanns' series men were more frequently affected than women. The age incidence in the majority of cases occurred during the third to fifth decades of life. The site of infection in the greatest number of cases (twenty-seven) occurred in the thighs. Hilgenfeld reported a case in which gas gangrene developed in both thighs after a hypodermoclysis. The following solutions named in the order of frequency were associated with the postinjection complication: (1) caffeine, (2) epinephrine, (3) physiologic solution of sodium chloride, (4) morphine and a number of lesser offenders. Of all these cases only four survived this catastrophe. The nature of the illness before the onset of this complication varied from all types of medical diseases to the usual variety of surgical procedures.

The pathogenesis of gas infection after hypodermoclysis is a local pressure ischemia caused by the solution itself. This, coupled with an endogenous lowered resistance and an introduction of the infective organism from an exogenous source, can account for the resultant gas infection. It has been shown

From the Surgical Service of the Kings County Hospital and Harbor
Ho pitel
1 Junghanns II Gas Gangrene Caused by Injection of Medica-
ments Deutsche med Wchn chr 59 850 (June 2) 1933

experimentally that the injection of gas bacilli into a particular area the main arterial branch of which is ligated will more readily yield to gas gangrene than a similar area the blood supply of which is undisturbed. It is also to be noted that the use of vasoconstrictors (epinephrine) causing local ischemia or protoplasmic coagulants (caffeine, quinine) producing areas of necrosis predispose to subsequent infection.

The senior author of this report has considered the site of injection for infusion an important factor for infection. He has required from his service associates that all clyses be given in the axillary region. It is his contention that an injection in the thigh, because of its proximity to the genitals and anus, is a decisive threat for gas infection. Junghanns figures sustain this thought. Nevertheless, gas gangrene may occur after any hypodermic injection anywhere in the body. We have tried to reduce to a minimum all other sources for infection by impressing on our house staff that every infusion be treated as a surgical operation requiring all the usual aseptic operative maneuvers.

REPORT OF CASES

CASE 1—H. P., a man, aged 60, was admitted August 17 with complaints referable to his stomach. X-ray studies indicated an obstructing pyloric ulcer, for which an operation was performed August 27. The following notes describe the course of events following a posterior gastro-enterostomy.

August 27. Temperature 100. Postoperative reaction good. Patient received two clyses into the thighs.

August 28. First postoperative day. Temperature 105. Pulse 120. General condition is weak this morning.

August 28, 2 25 p. m. General condition good. Patient improved. No distention. Patient complains of pain in the left thigh. Anterior aspect of left thigh edematous and rather tense. Subcutaneous crepitus is probably due to air from clysis needles. Will observe for infection.

August 28, 11 30 p. m. Patient has a remittant temperature from 101 to 105. Complains only of pain in left thigh. Receiving clysis in axilla now. No abdominal distention. Wet dressing to left thigh. Culture of wound taken and sent to laboratory.

August 28, midnight. The infection is rapidly spreading. Crepitation is marked over whole left thigh and up to Poupart's ligament. Extensive brawny induration from Poupart's ligament down to foot. Clinical picture is that of a gas infection. Condition of patient is critical.

August 29, 2 a. m. Small incisions about 3 inches long made over anterior aspect of thigh under procaine hydrochloride anesthesia. Large amount of foul smelling gas escaped through incisions. Gas antiserum given intravenously. Patient died 2 20 a. m., August 30.

CASE 2—Mrs. M. C., aged 38, was admitted July 6 because of gallstones. Cholecystectomy was done July 28. Postoperatively she received daily hypodermoclyses of 1,000 cc. of 5 per cent solution of dextrose. August 1 she showed on the outer side of the right breast a gangrenous area about 3 inches in diameter. Crepitation was present and extended toward the sternum. Incisions were made into the gangrenous area and a culture was taken. The patient received 200 cc. intravenously of antigas serum. A transfusion of 500 cc. of citrated blood was given. Smear and culture were both positive for the gas bacillus. She succumbed to the infection the following day.

CASE 3—Mrs. R. S., aged 34, was admitted April 9 1935, complaining of pain in the right upper quadrant, which radiated to the right shoulder.

April 16 cholecystectomy was performed. She received daily clyses of 5 per cent dextrose and saline solution. On the third postoperative day the temperature rose to 103. Previous maximum postoperative temperatures were never above 100.

April 19 the patient was flushed and complained of a pain in the right pectoral region at the site of the hypodermoclysis. Wet dressings were to be applied. The abdomen was soft and there was no nausea or vomiting.

April 20 the patient's temperature was still high. In the right pectoral region there was a large red and swollen area of skin about 3 inches in diameter. Over the center of this inflammatory mass was a bleb about the size of a grape seed. Crepitation could be elicited. A culture and smear were taken from the bleb. The gas bacillus was identified in the smear examination.

The patient was immediately operated on. An incision was made parallel to the curve of the breast. The breast was raised up from the chest wall and the entire area packed with peroxide dressings. A small area of the pectoralis major was gangrenous and a foul odor emanated from the wound. Cultures of the excised necrotic tissue yielded the gas organism. The patient received gas antiserum. Thereafter the patient improved and was finally discharged May 7.

CURE OF DIABETES INSIPIDUS COINCIDENT WITH BILATERAL CORRECTION OF ABDOMINAL CRYPTORCHIDISM

BY GONADOTROPIC FACTOR FROM PREGNANCY URINE

ARTHUR A. ALLEN, M.D., AND JAMES S. STOKES, M.D.
PATERSON, N. J.

In presenting this case, no claim is made for originality of technic or medication. The medicament employed was the standard gonadotropic factor from pregnancy urine,¹ and the method of injection was routine.

However, the remarkable results obtained and the coincident relief of the symptoms of diabetes insipidus have led us to conjecture on the possibilities of our having stumbled on a new treatment for diabetes insipidus. The following is a summary of the case.

REPORT OF CASE

L. S., a boy, aged 11 years, was short of stature, somewhat mentally retarded and lacking in normal vigor and ambitions of a boy of his age and social opportunities.

He had a normal, full term birth, there was a nutritional problem in infancy, with a tendency toward obesity. Besides the usual childhood exanthemas, which were uncomplicated, he was given antitoxin in 1928 for diphtheria and the disease was aborted. The tonsils and adenoids were removed in 1929, followed by a subsequent resection of hypertrophied lymphoid tissue from the nasopharynx five years later. For the past three years he had shown evidences of retarded mental development and had suffered from polyuria, polydipsia, nocturia and enuresis. In his anxiety to avoid the embarrassment of enuresis, he voided sometimes as often as every half hour, and as much as 6 liters of urine in twenty-four hours.

On admission the temperature was 98 F., the pulse 85, respiration rate 20 and blood pressure 105 systolic, 85 diastolic. He was 51½ inches (131 cm.) tall and weighed 80 pounds (36½ Kg.). The skin was clear and the mucous membranes were normal. The pupils were equal and reacted normally to light. The conjunctiva was normal in appearance. The ears, the nose and the buccal cavity were essentially normal. The throat, however, presented patches of hypertrophied lymphoid tissue. The lungs were clear and resonant throughout. The heart rate and rhythm were normal with no audible murmurs. Examination of the abdomen showed no tumor, tension or tenderness. Genito-urinary examination revealed that the foreskin was easily retractable. There was bilateral abdominal cryptorchidism and a suggestion of feminine distribution of pubic hair. The prostate gland could not be palpated. The blood count was normal. The Wassermann reaction was negative and urinalysis was essentially negative except for a low specific gravity (1.002) and excessive twenty-four hour output (from 6 to 8 liters).

From the physical examination and laboratory results we diagnosed the case as one of bilateral cryptorchidism with adiposis genitalis and diabetes insipidus.

The youth had been treated for two years by various physicians for these conditions and the treatment had been essentially solution of posterior pituitary and anterior pituitary products, with no apparent results. We therefore consulted with genito-urinary specialists on the procedure most desirable. One agreed with us that gonadotropic factor from the urine of pregnancy might stimulate the descent of the testes, another insisted that surgical intervention was necessary because the testes were definitely abdominal. Neither was enthusiastic about the possible success of a strictly medical procedure.

¹ Antuitrin S. Parke Davis & Co. was the gonadotropic substance used.

During a period of sixty days between Nov. 2, 1934, and Jan. 2, 1935, we gave the youth a series of twenty-five 1 cc subcutaneous injections of gonadotropic factor from pregnancy urine with the following results:

December 3, following the fifteenth injection, both testes were palpable in the scrotum but receded into the lower end of the canals before the next injection was given. All symptoms of polyuria and polydipsia, enuresis and nocturia had disappeared, both testes were visible by transillumination in the scrotum and showed evidences of growth.

Jan. 2, 1935, when the twenty-fifth and last injection of this series was given, the child had undergone remarkable mental advance. His increased activities had reduced his weight about 7 pounds (3.2 Kg.), with the reduction most marked around the genitalia. The pubic hair was assuming a masculine distribution and the prostate was slightly palpable. The diabetes insipidus was apparently cured.

October 2, after nine months without any treatment, the patient was again examined, and no retrogressive signs had appeared. The boy's father remarked that the child was even "picking fights with boys who had usually bullied him before."

COMMENT

Practically all authorities agree that diabetes insipidus is associated with or results from disturbances in the hypophysis. Here is a case in which the usual treatment with pituitary substances neither caused the descent of the testes nor relieved the diabetes insipidus. Gonadotropic factor from pregnancy urine stimulated complete descent of the testes, cured the diabetes insipidus and improved the intelligence quotient of this child.

From our point of view, the remarkable results obtained by gonadotropic factor from pregnancy urine in causing the complete descent of the testes is overshadowed by the possibility that we may have stumbled on a cure for diabetes insipidus, as evidenced by comments on our results contained in a letter from Dr. Samuel Cohn of San Francisco, who states: "The relief of symptoms of diabetes insipidus is an interesting side issue in this case and may open up a new treatment for this disease."

It seems logical to conclude that the pregnancy hormone present in this substance stimulated the internal secretion of the testes as is very evident, and in this way may have exerted an indirect effect on the pituitary gland which was not possible by direct stimulation, and that the indirect stimulation of the pituitary gland with gonadotropic factor from pregnancy urine cured the diabetes insipidus.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT

HOWARD A. CARTER, Secretary

BURDICK RADIANT HEAT LAMP ACCEPTABLE

Manufacturer: The Burdick Corporation, Milton, Wis.

This is a professional infra-red lamp recommended for use in physicians' offices and hospitals. It has a double wall reflector. The inner reflector is of porcelain enamel steel and has a Pyrex glass protection shield. The stand is counterbalanced and has a 30 inch vertical adjustment swivel cross arm with 25 inch extension and 10 inch adjustment, and a mobile base equipped with large rubber-tired casters. It is possible to interchange the 1,000 watt infra-red heating element with a nonmetallic surface heating element.

The firm submitted tests showing the radiant energy distribution of the lamp. At a distance of 30 inches from the screen at the bottom of the reflector the spread of the radiant energy was measured by a photronic cell and ammeter in a two foot circle. The distribution of energy was such that the readings were 15 per cent higher at the center than at the periphery of the circle. It would appear, therefore, that the radiant energy distribution was uniform and the reflector was designed to prevent hot spots.

This unit was tried out in a clinic acceptable to the Council and rendered satisfactory service.

In view of the aforementioned report, the Council voted to include the Burdick Radiant Heat Lamp in its list of accepted devices.

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT

PAUL NICHOLAS LEECH, Secretary

THE TRYPARSAMIDE PATENT AND TRADEMARK

Tryparsamide is an arsenical preparation originally proposed for treatment of trypanosomiasis but now used as well in certain cases of syphilis of the central nervous system. The product is at present manufactured and marketed by Merck and Co., Inc., and formerly by Powers-Weightman-Rosengarten Co., now merged with Merck and Co., Inc., under U. S. patents and trademark registration by license from the Rockefeller Institute for Medical Research, which owns both the patents and the trademark. It was accepted by the Council on Pharmacy and Chemistry for inclusion in New and Non-official Remedies in 1925. Although from time to time the Council has recognized meritorious products marketed under monopolistic patents, it has never felt that such monopolies, especially when commercially controlled, were wholly in the best interests of medicine or of the general public.

The justification for patenting a worthwhile medical preparation lies in the opportunity this procedure affords of controlling the quality and purity of the preparation involved for the purpose of protecting the public from the marketing of specious or impure products. This is particularly true of a drug such as Tryparsamide, which, the Council is informed by the Rockefeller Institute, requires unusual care in its preparation to insure that degree of purity which is essential for proper use. The divorce of commercial control from the administration of a patent is in the interest of making the patent socially beneficent and serviceable. Such has been the case with the Tryparsamide patent which has been administered by the Rockefeller Institute. That body has derived no financial gain but has, through careful oversight of its licensee, been able to insure the marketing of a carefully manufactured, adequately standardized product.

In view of the fact that the patent expired Sept. 24, 1935, a large manufacturing firm inquired of the Secretary of the Council whether the Council would adopt a nonproprietary designation under which Tryparsamide could be marketed. This raised the question of the virtual perpetuation of monopolies by the use of trademark rights, which go on indefinitely after a patent has expired. This is a pernicious practice, since the establishment of a name through the seventeen years of the life of a patent makes it difficult to market a product under a new name.

On Oct. 9, 1935, the Secretary inquired of the Rockefeller Institute whether it intended to dedicate the name Tryparsamide to the public as a nonproprietary designation on the expiration of the patents. The institute informed the Secretary that it not only planned to dedicate the name to the public as a nonproprietary designation but had already taken steps to that end both in the United States and in numerous foreign countries. The Council therefore adopted Tryparsamide as a nonproprietary name for the product which has been marketed under that name as a proprietary designation.

In advising the Secretary of its decision, the Institute expressed the hope that the freedom to use this name which the institute was giving to the public would not result in ill advised competition among drug manufacturers undertaking to make Tryparsamide because it would be unfortunate if, as a result of such competition, production costs were lowered to the point at which the present high quality of the drug was jeopardized with dangerous consequences to the public.

In appreciation of the excellent way in which the Institute has administered the patent on Trypsamide and in recognition of its altruism in waiving trademark rights, the Council authorized publication of the foregoing statement

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH Secretary

MERTHIOLATE (See New and Nonofficial Remedies, 1935, p 313)

The following dosage form has been accepted

Saf T Top Tincture of Merthiolate 1 1000 Tincture of merthiolate 1 1000 marketed in Saf T Top containers (glass ampules having a capillary opening) containing 2 cc and 15 cc
Prepared by Robert A Bernhard Rochester N Y

PROCAINE HYDROCHLORIDE (See New and Nonofficial Remedies, 1935, p 62)

The following dosage form has been accepted

Ampul Solution Procaine Hydrochloride with Epinephrine 1 cc Each cubic centimeter contains procaine hydrochloride U S P 0.02 Gm (½ grain) epinephrine hydrochloride 0.04 mg (1/1600 grain) and sodium bisulfite 0.45 mg (1/144 grain) in aqueous solution
Prepared by the U S Standard Products Co Woodworth Wis No U S patent or trademark

Committee on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

FRANKLIN C BING Secretary

CELLU BRAND MUSHROOMS WATER PACKED

Distributor—Chicago Dietetic Supply House, Inc, Chicago

Packer—Michigan Mushroom Company, Niles, Mich

Description—Canned whole mushrooms, packed in water

Manufacture—Mushrooms, grown from a culture of pure mushroom spawn, are picked at the proper stage of maturity, cleaned, spots cut out, washed, inspected, blanched and packed into cans. The cans are filled with water, sealed and processed.

Analysis (submitted by distributor) —

	per cent
Moisture	93.6
Total solids	6.4
Ash	0.6
Fat (ether extract)	0.2
Protein (N × 6.25)	1.9
Crude fiber	0.4
Starch (diastase method)	2.6
Carbohydrates other than crude fiber (by difference)	3.3

Calories—0.2 per gram 6 per ounce

Claims of Manufacturer—Choice quality whole mushrooms packed without added sugar or salt. For use in special diets in which sugar or salt is proscribed or in quantitative diets of calculated composition.

BORDEN'S MALTED MILK

Manufacturer—Borden's Milk Products Company, Inc, New York, subsidiary of the Borden Company, New York

Description—Malted milk prepared from whole milk, wheat, flour, barley malt and sodium chloride.

Manufacture—A mash of barley malt, wheat flour and water is maintained at a definite temperature until the starch has been completely converted and filtered. The filtrate is partially neutralized with sodium bicarbonate mixed with pasteurized milk, held for a period concentrated in vacuum pans and dried in finishing pans or on drum driers to 2 per cent mois-

ture content. The dried product is ground, salt is added, and it is packed.

Analysis (submitted by manufacturer) —

Vitamins—Biologic assay shows approximately 180 U S P units of vitamin A, 70 Sherman-Chase units of vitamin B and 60 Sherman-Bourquin units of vitamin G per ounce.

Claims of Manufacturer—Excellent source of food energy, biologically efficient proteins and the minerals calcium and phosphorus, good source of vitamins A, B and G.

WILKINS TEA ORANGE PEKOE

Manufacturer—John H Wilkins Company, Washington, D C

Description—Blend of black fermented Orange Pekoe teas.

Manufacture—Young tender tea leaves are hand picked withered for from ten to thirty hours to remove some of the moisture, rolled to break open the cells and distribute the juice over the surface of the leaves, fermented to develop aroma and color, spread on wire trays and dried in a current of hot air to check the fermentation. The dry tea is sorted in sifting machines into various grades and stored in aluminum lined chests. Teas of various varieties are carefully blended to produce a uniformly flavored product, and packed in glassine bags in cartons.

1 HOME BRAND FLAVORED CRYSTAL WHITE SYRUP

2 FOLEY'S BRAND FLAVORED CRYSTAL WHITE SYRUP

Distributors—1 Griggs, Cooper & Company, St Paul
2 Foley Bros Grocery Company, St Paul Subsidiary of Griggs, Cooper & Company

Manufacturer—Griggs, Cooper & Company, St Paul

Description—Table syrups, corn syrup with invert sugar syrup flavored with vanillin and coumarin.

Manufacture—Definite quantities of corn syrup invert sugar syrup water and flavor are mixed, heated, strained and automatically filled into cans.

Analysis (submitted by manufacturer) —

No methods are available for accurately determining the composition of syrups of this nature, therefore the foregoing analysis is roughly approximate.

Calories—3 per gram 85 per ounce

Claims of Manufacturer—Recommended for use as an easily digestible and readily assimilable carbohydrate supplement to milk in infant feeding and as a syrup for cooking, baking and the table.

HOSPITAL SERVICE IN THE UNITED STATES

FIFTEENTH ANNUAL PRESENTATION OF HOSPITAL DATA BY THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS OF THE AMERICAN MEDICAL ASSOCIATION

Outstanding facts shown by the Annual Census of Hospitals for 1935 are fewer hospitals, increased capacity and increased occupancy. The period covered by the census corresponds nearly with the calendar year 1935. Answers were received from 96 per cent of the hospitals, representing about 99 per cent of the total bed capacity. The total number of registered hospitals is 6,246 as compared with 6,334 last year, a net loss of eighty-eight.

The capacity of all registered hospitals is 1,076,350 beds and 53,310 bassinets, a gain for the year of 28,249 beds and 284 bassinets.

General hospitals gained 12,749 beds and 901 bassinets.

fifteen, according to the estimated census, was a hospital bed patient in 1935.

Growth of hospital facilities for the last twenty-six years has been at the rate of 25,203 beds a year. This is the equivalent of sixty-nine beds for every day in the twenty-six years.

There are 4,364 hospitals that have their own laboratories, 3,115 of which are directed by physicians, while 275 admitted having nurses for directors.

Roentgen-ray departments were reported by 4,698 hospitals, with 3,686 physician-directors and 278 nurse-directors.

Hospitals reporting patients' libraries numbered 2,749.

1935	Hospitals	Beds	Bassinets	Patients Admitted	Average Census
Nonprofit	2,640	268,568	36,152	4,477,515	167,680
Profit (unrestricted)	1,882	64,859	8,741	946,587	32,909
Governmental	1,724	742,923	8,417	2,285,840	676,100
Totals	6,246	1,076,350	53,310	7,709,942	876,689

Nonprofit organizations have 2,640, or about two fifths of the entire number of hospitals. Governmental agencies maintain 742,923 beds, or more than twice as many as the nonprofit and for profit organizations combined. On the other hand, nonprofit organizations admitted 4,477,515 patients, or almost twice as many as all governmental agencies, even though the latter include county and city hospitals. Nongovernmental hospitals have 44,893 bassinets out of a total of 53,310 in all hospitals. Governmental hospitals have an average census of 676,100, or about three times that of the combined nongovernmental organizations. The figures prove the necessity of government responsibility for indigent, custodial and chronic care, and non-government or voluntary care for that large number whose disabilities are acute, the stay comparatively short, and most of whom have available financial resources. The reader will not overlook the contrast between the figures for the nonprofit and those for the for profit organizations.

The average number of idle beds was 199,661, of which 144,880 were in general hospitals.

The total patients admitted not counting the new-born infants, was 7,709,942, a gain of 562,526 over last year.

The average daily census of patients of all registered hospitals was 876,689, a gain of 46,591.

The increase in capacity during 1935 is equivalent to a complete seventy-seven bed hospital for every day in the year including Sundays and holidays. This is in addition to replacements.

Hospitals are admitting bed patients at the rate of one patient every four seconds throughout the year.

The 4,257 general hospitals admitted 6,867,870 patients or 89.07 per cent of the 7,709,942 patients admitted to all hospitals. However the total patient days in general hospitals was only 95,372,310, or 29.8 per cent of 319,991,485 patient days in all hospitals.

The average length of stay per patient in general hospitals was fourteen days.

The 769,660 babies born in hospitals in 1935 means an increase of 68,517 over 1934. General hospitals reported 732,465 births and maternity hospitals 35,784.

Using the population estimated for 1935 by the United States Bureau of the Census, one person in

Seven hundred and seventeen hospitals have their own ambulances, and 533 of these reported a total of 802,930 ambulance calls.

The 2,476 hospitals said to have outpatient departments reported 9,712,862 outpatients, who made 35,588,640 visits to the outpatient departments.

In the foregoing paragraphs and throughout this article the figures for "patients admitted" and "average daily census of patients" are exclusive of new-born infants and do not include outpatients.

Reference to outpatient departments, ambulances, schools of nursing and so on are not to be understood as requirements or even as arguments for the maintaining of such facilities by all hospitals. Hospital facilities should be provided in accordance with the needs of any given institution for the best and expeditious care of its patients.

Some idea of the immense proportions of hospital enterprises in all states may be easily obtained by looking at the grand totals of the number of hospitals, their capacity and the number of patients accommodated.

In New York State alone there are 588 registered hospitals under several kinds of control and all types of service with a grand total capacity of 166,843 beds.

and 7,625 bassinets. The number of persons in that state who made use of hospital beds during the year was 1,123,533. The average census of the citizens of the state in all those registered hospitals was 141,277.

The nearest second to New York is Pennsylvania, with its total of 360 registered hospitals and a bed capacity of 80,969 and 4,385 bassinets. There were 595,904 patients admitted and the average census was 66,223.

The volume of hospital service in Illinois is third, with 321 hospitals, 75,949 beds, 4,050 bassinets, 543,141 patients admitted and an average census of 60,553. California exhibits 368 registered hospitals, 64,315 beds and 3,062 bassinets, a total of 487,433 admissions and an average census of 53,895.

The column that yielded these figures shows five additional states in each of which more than 250,000 were admitted to hospitals for bed care during the year. These are Massachusetts, 351,791; Ohio, 351,785; Michigan, 306,960; New Jersey, 269,057; and Texas, 270,427.

Other states in which more than 100,000 patients were admitted during the year are Connecticut, Georgia, Indiana, Iowa, Kansas, Louisiana, Maryland, Minnesota, Missouri, North Carolina, Tennessee, Virginia, Washington, West Virginia and Wisconsin.

New-born infants are not counted in the figures here given either for the patients admitted or for the average census.

IDLE BEDS

An accompanying map shows at a glance the percentage of occupancy prevailing in general hospitals for each state. The different sections of the United

beds in hospitals grouped according to type of service. The average number of idle beds for the year 1935 is 199,661, as compared with 216,775 in 1933 and 180,367 in 1929. The idle beds in general hospitals numbered 144,880. All governmental hospitals, federal, state and

Percentages of Beds Occupied

Hospital departments of institutions	63.0	63.9	60.1	66.6
All other hospitals	74.6	69.2	79.3	86.9
Total all hospitals	80.1	79.6	78.8	81.4

local had an average of 66,823 idle beds. The nonprofit associations, such as churches, fraternal organizations and independent associations, maintain 100,888 idle beds.

A separate table shows percentage of beds occupied in the different groups of hospitals, showing trends over the past six years. General hospitals had an occupancy of 64.3 per cent in 1935 as against 59.9 per cent in 1933. Nervous and mental hospitals show an occupancy of 95.8 per cent as compared with 95.1 per cent in 1933. Overcrowding is a chronic situation in the majority of state mental hospitals. Tuberculosis hospitals as a group show an occupancy rate of 85.4 per cent, maternity hospitals, 58.3 per cent, industrial, 46 per cent, eye, ear, nose and throat hospitals, 48.1 per cent, children's hospitals, 63.9 per cent, and orthopedic hospitals, 78.3 per cent.

GOVERNMENTAL HOSPITALS

Practically every unit of government has found it necessary or expedient to engage in the hospitalization of the sick and injured. Different departments of the federal government maintain hospitals for the Army, the Navy, the Public Health Service, Veterans, Indians and a few others.

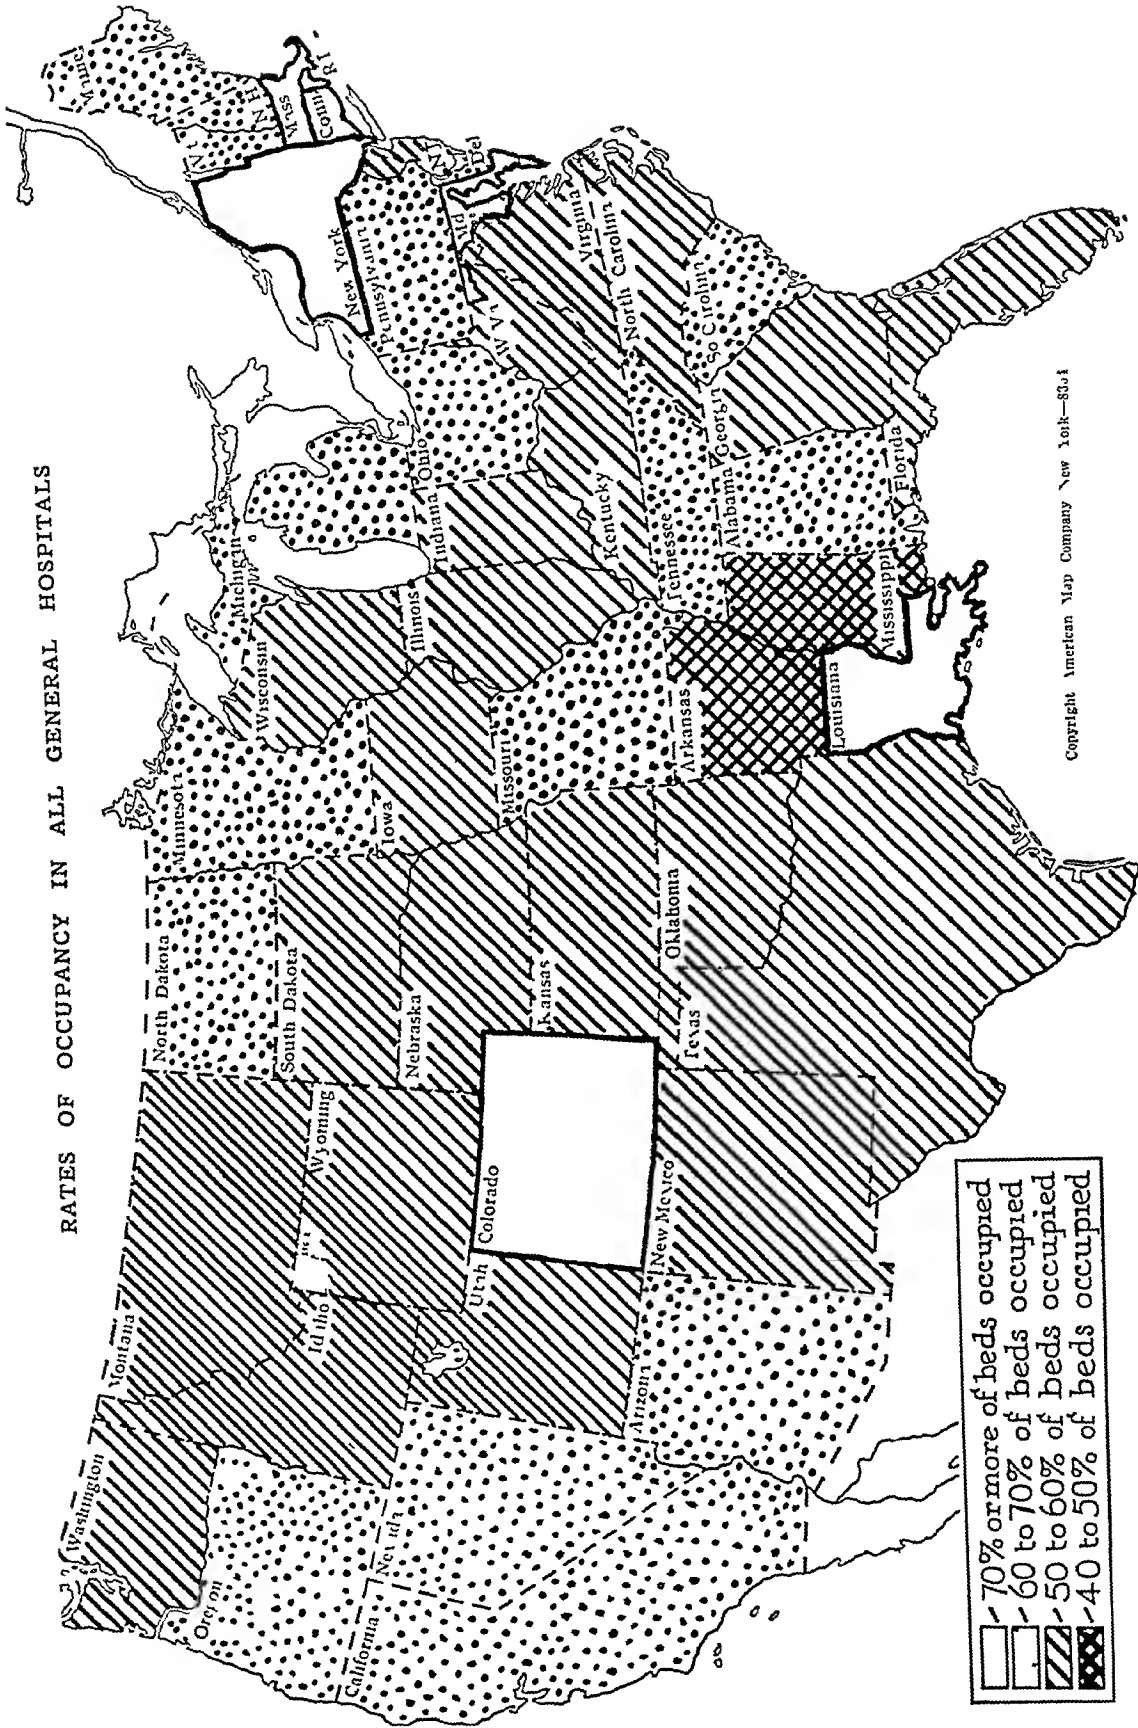

State governments have assumed the duty of providing hospitalization for indigent patients suffering from mental diseases and from tuberculosis. This has given rise to a large system of state mental hospitals. In Wisconsin, custodial care of the insane is provided by counties. Only facilities for study and diagnosis are maintained by the state. The states assume the care of those suffering from tuberculosis and mental diseases because these ailments produce a period of disability longer than the finances of the average citizen will carry him.

Unoccupied Beds in Hospitals

All other hospitals	2,264	1,720	1,535
Total unoccupied beds—all hospitals	180,367	216,775	199,661

States vary greatly in the extent to which the people make use of hospitals. Worthwhile of special study is the table that tells the number of unoccupied beds. It shows trends by comparing figures for 1929, 1933 and 1935. The first section of the table reports for all registered hospitals grouped according to ownership or control and the second section shows the empty

RATES OF OCCUPANCY IN ALL GENERAL HOSPITALS

Occupancy in General Hospitals

The percentages of beds occupied in general hospitals during the year 1935, by states, were as follows

Alabama	59.9	District of Columbia	69.8	Kansas	57.1	Minnesota	63.1	New Jersey	70.0	Oregon	60.6	Utah	54.7
Arizona	60.6	Florida	60.2	Kentucky	54.1	Mississippi	40.6	New Mexico	53.7	Pennsylvania	60.6	Vermont	60.6
Arkansas	49.4	Georgia	60.1	Louisiana	63.6	Montana	64.7	New York	63.3	Rhode Island	60.2	Virginia	58.1
California	60.1	Idaho	54.7	Maine	64.3	Nebraska	58.0	North Carolina	53.3	South Carolina	60.2	West Virginia	54.5
Colorado	48.9	Illinois	57.7	Maryland	64.3	Nevada	68.1	North Dakota	64.6	South Dakota	60.8	Wisconsin	58.9
Connecticut	60.3	Indiana	56.5	Massachusetts	70.8	New Hampshire	63.3	Ohio	63.3	Tennessee	63.2	Wyoming	61.2
Delaware	60.1	Iowa	56.4	Michigan	67.5	New Jersey	60.2	Oklahoma	50.0	Texas	53.7		

For the general care of the indigent and with special relation to injuries and to diseases other than mental and tuberculosis, hospitalization has been assumed by county and city governments or by the two combined Medical services in these hospitals are usually rendered by physicians dwelling within the confines of the county or the city

Regarding growth of governmental hospitalization, in 1923 there were 1,736 of all types of government institutions including federal, state and local, and they had an aggregate capacity of 471,948 beds, in 1927 our census showed 1,809 with a bed capacity of 545,169, in 1935 we found 1,724 governmental hospitals with a capacity of 742,923, admitting 2,285,840 patients and having a constant patient population of 676,100. A very fruitful source of facts on this growth is contained in table 1, section A. The federal hospitals now number 316, with a capacity of 83,353 beds and 604 bassinets. The number of patients admitted reached the unprecedented total of 382,980 and the average census was 64,795. Looming still larger is the work of the state hospitals, which number 526 but have a total capacity of 485,205 beds and 1,186 bassinets. They admitted 506,133 patients and had a constant census of 463,249. The apparent decline in the number of state hospitals from 592 in 1927 to 526 in 1935

Summary of Growth of Hospitals 1909 to 1935

Year	Federal Hospitals		State Hospitals		All Other Hospitals		Total	
	Num ber	Capac ity	Num ber	Capac ity	Num ber	Capac ity	Num ber	Capac ity
1909	71	8 827	232	189 049	4 006	223 189	4 309	421 065
1914	93	12 602	294	232 834	4 600	257 045	5 087	532 481
1918	110	18 815	303	282 204	4 910	331 182	5 323	612 201
1923	220	53 869	601	302 208	6 009	399 645	6 830	700 722
1925	224	61 765	590	369 709	5 963	461 410	6 852	892 934
1927	231	69 170	576	419 282	5 746	450 663	6 613	974 115
1931	301	74 151	568	442 601	5 693	497 602	6 562	1 014 354
1932	290	70 680	507	409 646	5 580	491 760	6 437	1 027 046
1933	290	70 680	507	409 646	5 580	491 760	6 437	1 027 046
1934	313	77 865	544	473 030	5 477	497 201	6 334	1 048 101
1935	316	83 353	526	485 205	5 404	507 792	6 246	1 076 350

is explained mainly by the discontinuance of hospital departments of various state custodial institutions, which found it more economical and effective to hospitalize their sick inmates in existing general hospitals of the community. The average size of governmental hospitals, both state and local, has increased tremendously in recent years. County hospitals now number 490 and they have 90,904 beds and 2,375 bassinets, admitted 476,275 patients in 1935 and had an average census of 79,280 patients. The number of patients admitted increased 22,850 over last year.

City hospitals remain about constant in number, there now being 328, the same as last year. They show a slow growth, now having 73,322 beds and 3,742 bassinets.

Hospitals operated by city and county governments jointly declined in number and in patient population, owing in part to the dropping out of one or the other member of the dual ownership, causing a reclassification either as a county hospital or as a city hospital.

NONPROFIT ORGANIZATIONS

There are 2,640 hospitals that are run by non-governmental, nonprofit organizations. They include churches, fraternal orders, and nonprofit corporations and associations organized for the express purpose of conducting a hospital.

The total capacity of the 2,640 nonprofit hospitals is 268,568 beds and 36,152 bassinets. Most of the hospitals in this group care for the acutely sick and injured

persons, including most types of ailment with the exception of contagious diseases, nervous and mental and tuberculosis. The rapid turnover and the large number of persons served are attested by the fact that 4,477,515 patients were admitted during the year 1935. This was an increase of 313,780 over the previous year.

CHURCH HOSPITALS

Among the nonprofit organizations, churches figure prominently. There are 970 church hospitals with a total capacity of 113,268 beds, and 16,033 bassinets. The patients admitted numbered 1,950,308 in 1935 as compared with 2,013,352 in 1931. Although the number of patients admitted by church hospitals decreased in the five year period, the last year shows a substantial increase. The majority of patients in church hospitals are pay patients, and it is to be expected that their patronage will fluctuate with business conditions.

The state holding the banner for number of church hospitals is Illinois with eighty-six, followed by New York with seventy-eight, Wisconsin with fifty-nine, Ohio with forty-eight, and Iowa and Pennsylvania with forty-two each.

FRATERNAL HOSPITALS

Fraternal hospitals have decreased since 1927 from eighty-five to sixty-nine. At the same time the number of beds has increased from 4,935 to 5,360. The number of patients admitted in fraternal hospitals is on the decrease, but the average census is increasing.

NONPROFIT CORPORATIONS AND ASSOCIATIONS

Nonprofit corporations and associations are organizations other than churches and fraternal orders each of which was brought into being for the sole purpose of operating a hospital at a given place. Usually the hospital is controlled by a board of trustees elected by the members of the hospital association, membership in the association being determined on the basis of donations or contributions. Such organizations are operating 1,601 hospitals, which have a capacity of 149,940 beds and 18,978 bassinets. They admitted 2,493,281 patients. In 1935 their average census was 94,468. Figures are available for comparison only with the previous year, and in that time they show increases in occupancy figures.

The state in which these are most numerous is New York with 212, followed by Pennsylvania with 189, Massachusetts with 103, Illinois with eighty-three, and Ohio with seventy-five.

PROPRIETARY ORGANIZATIONS

The classification of proprietary organizations embraces those hospitals usually spoken of as being operated "for profit." They may be divided into two groups, those operated by individuals and partnerships and those run by corporations that are unrestricted as to profit, they may or may not make a profit, but their form of organization does not keep them from it.

INDIVIDUAL AND PARTNERSHIP

The individual and partnership hospitals number 1,255. They have a capacity of 29,913 beds and 4,384 bassinets. They admitted 413,997 patients during the year and their average census was 14,212. There seems to be a pronounced downward trend here, since these hospitals numbered 1,682 in 1927 with a capacity of 39,118 beds. Nevertheless, this type of control and ownership is especially useful in communities where hospitals on a plan of broader cooperation cannot be obtained.

Conspicuous for the number of individually owned and partnership hospitals are California and Texas, each with 106, New York with seventy-five, Minnesota with seventy-two, Nebraska with forty-nine and Oklahoma with forty-seven

CORPORATIONS (UNRESTRICTED AS TO PROFIT)

Corporations unrestricted as to profit are frequently called "stock" hospitals. Figures on them as a segregated classification have been obtained only for two

TOTALS FOR NONGOVERNMENTAL HOSPITALS

The summary of tables 1 B and 1 C indicates that nongovernmental hospitals show a decline in number but show an increase in capacity and in the number of persons served. The total nongovernmental hospitals is 4,522, with a capacity of 333,427 beds and 44,893 bassinets. They admitted 5,424,102 patients last year as contrasted with 2,285,840 patients, the number admitted by all governmental hospitals.

The list beginning on page 798 was subject to additions and removals of hospitals until going to press. Totals of the list therefore may vary slightly from tables 1 and 2 which were prepared as of Dec 31 1935.

years. Their number is 627, with a capacity of 34 946 beds and 4,357 bassinets. Patients admitted in 1935 numbered 532 590 and the average census was 18 697. An increase in the amount of work during the past year is noticeable, considering that they receive almost wholly pay patients.

The total number of hospitals understood to be operating for profit or with a possibility of profit, therefore, numbers 1 882. They have 64,859 beds and 8 741 bassinets. They admitted 946 587 patients and their average census was 32,909.

HOSPITALS ACCORDING TO TYPE OF SERVICE

GENERAL HOSPITALS

The trend as to the number of general hospitals has been downward for the past eight years. The census of 1935 gives a total of 4,257 general hospitals, as compared with 4 361 in 1928. Comparison of capacity of general hospitals for the two years mentioned tells quite a different story. In 1928 there were 363,337 beds in general hospitals as compared with 406 174, an

increase of 42,837 beds. In the same period, bassinets in general hospitals increased from 38,339 to 48,757. The total number of patients admitted in general hospitals in 1931, the first year for which this figure is available, was 6,321,861, in 1935 the general hospitals admitted 6,867,870. In 1927 the average census of patients in general hospitals was 228,084, in 1935 it was 261,294.

The rate of increase in capacity and increase in patient population in the general hospitals has been

showed that 418 of the general hospitals have tuberculosis departments, aggregating 14,468 beds. These departments admitted 37,124 patients in the year 1934. An unknown number of general hospitals also take care of contagious diseases and mental cases.

The training of interns in their fifth year in medicine is limited almost entirely to general hospitals, 708 of which provide a total of 6,500 approved internships. Of the 405 hospitals approved for residencies in specialties, 193 of these are general hospitals providing

NERVOUS AND MENTAL HOSPITALS

During the past year, hospitals for nervous and mental patients have decreased from 614 to 592 and in the same time the capacity has increased from 513,845 to 530,522, a net increase in capacity of 16,677 beds. Patients admitted during 1935 numbered 173,109, an increase of 694 over the record of the previous year. The average census of patients was 508,448, as compared with 488,481 a year ago. The percentage of beds occupied was 95.84. The 592 hospitals in this classification include mental, nervous and mental, mentally deficient, epileptic, and institutions for special types.

TUBERCULOSIS HOSPITALS

The registered institutions devoted exclusively to the care of patients suffering from tuberculosis numbered 496, a gain of one during the year. Their capacity is 70,373, which is a gain of 310 during the year. The number of patients admitted was 86,113, as against 82,455 for the previous year. The average census was 60,738, as compared with 59,689 for the previous year. The figures here given for tuberculosis hospitals do not

include the tuberculosis departments of general hospitals. The percentage of beds occupied is 86.43.

A complete report on tuberculosis hospitals and sanatoriums and the tuberculosis departments of other hospitals was published in the Tuberculosis Number of THE JOURNAL, Dec 7, 1935.

MATERNITY HOSPITALS

The maternity hospitals now number 121, having lost nine since the last census. The capacity is 6,141 beds and 3,825 bassinets. In the last previous census there were 7,625 beds and 4,131 bassinets. Total patients admitted, not including new-born infants, during the year 1935 was 66,693 compared with 76,980 for the previous year. The average census of these patients was 3,582, as compared with 4,647 of last year. Bed occupancy was 58.33 per cent.

Births in maternity hospitals numbered 35,784, or 4.6 per cent of the births in all hospitals. The cor-

* Owing to reclassification births in industrial hospitals are carried under the heading "All other hospitals."

responding percentage for 1934 was 6.8 and for 1933 it was 10.

INDUSTRIAL HOSPITALS

The classification of industrial hospitals includes hospitals that are devoted exclusively or mainly to the care of accidents and conditions arising in industries. They are run by railroads, mills and other industrial plants. A number of these were found to have become more general than industrial. They have been reclassified as general hospitals.

The number of industrial hospitals now, therefore, is only fifty-two, as compared with 113 a year ago. The total number of beds in these hospitals is 3,421. They admitted 41,432 bed patients and the average census was 1,576. The bed occupancy was 46.07 per cent.

EYE, EAR, NOSE AND THROAT HOSPITALS

The eye, ear, nose and throat hospital also tends to decrease in number. There are at present forty-four of these as compared with fifty-five last year. The capacity is 2,263, they admitted 97,181 patients and had an average census of 1,089. The percentage of occupancy was 48.12.

CHILDREN'S HOSPITALS

The fifty-one children's hospitals now in the Register have a total capacity of 4 874 beds and 118 bassinets. They admitted 83 015 patients and had an average census of 3 115. The percentage of all beds occupied during 1935 was 63.91.

Complete figures are not available on children admitted to general hospitals. There can be no reasonable doubt that the figures would be several times as large as for children's hospitals.

A glance at the column headed "Children's" in table 2 will show the trend in children's hospitals year by

ISOLATION HOSPITALS

The trend in isolation hospitals as shown in table 2 is downward as to number and slightly upward as to number of patients admitted and the average census. The sixty-six hospitals now in existence under this classification are mainly well equipped institutions for the study of contagious diseases, isolation per se being one object in their design.

They have a capacity of 7 384 beds and seventy bassinets, and they admitted 47 004 patients last year. The average census was 3 301. The percentage of occupancy was 44.70.

year since 1927, there being in that time some decrease both in the capacity of those hospitals and in the number of patients admitted. The average size of those in existence is larger than in 1927.

ORTHOPEDIC HOSPITALS

There are sixty-eight orthopedic hospitals with a capacity of 6 394 beds. They admitted 28 280 patients and had an average census of 5 010. The total capacity of these hospitals remained about the same with only a slight increase in the number of patients admitted. The percentage of beds occupied was 78.35.

Separate figures for the orthopedic departments of general and other hospitals have not been obtained. They would without doubt show a great deal more work done in those departments than in the special orthopedic hospitals.

An increasing amount of hospitalization of contagious diseases is carried out by general hospitals, actual figures for which have not been obtained.

CONVALESCENT AND REST HOSPITALS

The classification of convalescent and rest hospitals comprises the least definite of all types of service. We have included only those hospitals that have reported themselves as specializing in providing for convalescence and rest and which provide adequate medical care and nursing service, with equipment sufficient for the purposes for which the institution was designed.

We have 135 of these institutions on the Register, with a capacity of 6 233 beds and thirty-four bassinets, admitting 28 218 patients and having an average census of 4 437. Seventy-two per cent of all beds were occupied during the past year.

Reference to the convalescent and rest column in table 2 shows that there are twenty states reporting no hospitals under this classification and about as many more showing only one or two such institutions. These states are, of course, not without facilities for convalescent care. Most of this service is provided by general hospitals, in which patients are quite welcome to remain throughout their period of convalescence.

Many places used for convalescence and more or less adapted for that purpose are not shown in the Register because they hardly seem to fit in with a classification of hospitals and sanatoriums. Accommodations for convalescents are also afforded for certain types of cases in various special hospitals, such as those for tuberculosis and for mental diseases. Nor can any one question the importance of the home from the standpoint of the amount of convalescence that takes place there.

INSTITUTIONAL HOSPITALS

A phenomenon worthy of notice in the hospital field is the decline in hospital departments of institutions, as

a result of the discontinuance of these hospital departments and transfer of patients to existing hospitals.

In 1927 there were 530 of these institutional hospitals as compared with 275 at the present time. Their capacity is 20,793 beds and 234 bassinets. Their importance is indicated by the fact that they admitted 143,434 patients last year and had an average census of 13,859. The percentage of beds occupied last year was 66.65.

PATHOLOGY DEPARTMENTS

The table summarizing pathology departments affords an opportunity to study the progress made in each state during the past year with regard to the number of clinical laboratories and the number in charge of physicians. New York State reported 409 hospitals having their

* Includes all departments reporting directors other than M D and all departments not reporting a director

own clinical laboratories with 341 in charge of physicians. Pennsylvania is second, with 285 laboratories with 243 in charge of physicians. Illinois reported 259 laboratories, with 189 in charge of physicians. California reported 236 laboratories, with 175 in charge of physicians. Texas reported 211 laboratories, with 137 in charge of physicians. Thus, a number of hospitals in every state of the union admitted that they were using nurses and lay technicians as directors of their laboratories, even though they admit that the practice of pathology is the practice of medicine. The total number of hospitals reporting their own clinical laboratories is 4,364, as against 4,271 in 1934. Those having physician-directors number 3,115, as against 2,950 a year ago. Those having lay and registered nurse directors number 1,249, as compared with 1,321 a year ago.

RADIOLOGY DEPARTMENTS

Increase of radiology in hospitals has been rather striking over a period of years.

The census shows a total of 4,698 hospitals having their own equipment, as compared with 4,589 a year

ago, an increase of 109. There were 3,686 directed by physician radiologists, as compared with 3,563 a year ago. The departments directed by lay technicians and registered nurses number 1,012, as compared with 1,026 a year ago.

New York has 438 departments with 388 physicians, Pennsylvania 274 departments with 246 physicians, California and Illinois tie each having 266 departments, California having 205 physicians and Illinois 204. Texas reported 234 departments using 167 physicians. All the states but Delaware and Rhode Island admitted having a number of departments without physician directors.

SCHOOLS OF NURSING

Schools of nursing were reported from every state except Nevada. The total number of schools reported was 1,476, and 1,444 of these are accredited by the board of nurse examiners of the state in which the school is located. One thousand two hundred and fifty-eight schools reported the number of students, their

Wisconsin	32	2	30	1,477
Wyoming	1	1	1	20
Total	1,476	1,444	1,258	60,046

aggregate enrollment being 65,046, an average of fifty-two per school. The average per school was forty-five in 1932. In 1930, 26 per cent of the hospitals had accredited schools of nursing; in 1935, 23 per cent. In the last five years the number of accredited schools has dropped 320, or 18 per cent, and in the last year the number has dropped eighty-seven, or about 6 per cent.

Reference to the tabulated returns seems to indicate that a considerable number of hospitals operating

schools of nursing evidently omitted to answer the question as to whether they had a school of nursing. This is noticeable in Illinois, in which the state board reports 121 schools and our census brought answers from only 106. The Pennsylvania board reported 128 schools and we heard from only 86.

Totals	2,749	717	533	802,930

It is hoped that all hospitals will answer this question in full next year, because of the keen interest on the part of many hospitals in the question whether or not to maintain a school of nursing.

PATIENTS' LIBRARIES

In this census for the first time the question was asked whether or not the hospital had a library for patients. The question was answered in the affirmative by 2,749 hospitals. Since the size and nature of the library was not stressed, little is known beyond the fact that it may be assumed that a wide variety of libraries would be found among the hospitals reporting.

There were 325 in New York, 187 in Pennsylvania, 168 in Massachusetts, 167 in California, 147 in Illinois, 108 in Ohio, and 103 in Michigan.

AMBULANCE SERVICE

Seven hundred and seventeen hospitals reported that they operate and own ambulances. The number of ambulance calls was reported by 533 hospitals, and the entire number of calls added up to 802,930.

Many hospitals that do not own ambulances obtain their ambulance service as needed through either private or public ambulance services.

HOSPITALS IN ALASKA, CANAL ZONE GUAM, HAWAII, PHILIPPINE ISLANDS, PUERTO RICO AND VIRGIN ISLANDS

A steady, slight increase in the hospital service for this group characterized the year 1935 as it did in former years. The Philippine Islands have 101 hos-

Hospitals in Alaska, Canal Zone, Guam, Hawaii, Philippine Islands, Puerto Rico and Virgin Islands

pitals. Puerto Rico has forty-nine hospitals, Hawaii has forty-seven hospitals, Alaska has nineteen hospitals, Canal Zone has ten hospitals, the Virgin Islands have five hospitals and Guam has two hospitals.

METHODS OF REGISTERING AND APPROVING HOSPITALS

The inclusion of any hospital in the Register is an indication that evidence concerning irregular or unsafe practices in that hospital has not been available to the Council on Medical Education and Hospitals. Considerable investigation is carried out in the case of each hospital before it is admitted to the Register.

First, hospitals supply information regarding their capacity, equipment, classification and list of staff. Each member of the staff is then looked up in the biographic files of the Association.

Second, a personal visit by a member of our staff of hospital examiners is made to each hospital approved, or applying for approval for internships or for residencies. An increasing number of other hospitals are being inspected.

Third, information and advice are obtained from the secretaries and other members of the county medical societies, from state, city or county health departments from the councilors of the state medical association for the district in which the hospital is located, and from other sources. Investigation of hospitals for internship and residency approval is more comprehensive than for registration.

The list of registered hospitals, by states, is presented on later pages of this issue, where considerable data are given about each hospital. Classifications, symbols and

strictly hospitals. In the statistics the two classifications are consolidated.

HOSPITALS REFUSED REGISTRATION

There are 564 institutions which, because of alleged unethical or questionable practices, admission to their staffs of members who are seriously unqualified, either morally or professionally, flagrant methods of advertising, or for other valid reasons, are deemed unworthy of being included in any published list of reputable hospitals.

Only a little over 1 per cent of the total capacity of all hospitals is included in the 564 institutions that are refused registration. From the standpoint of hospitalization, therefore, they are as a rule not needed.

abbreviations are explained at the head of the list. The list in each state is given in two sections: (1) hospitals and sanatoriums, and (2) related institutions. The related institutions include some general hospitals lacking certain essentials: nursing homes, school infirmaries, prison infirmaries, custodial and other institutions designed to give some medical, nursing or convalescent care in an ethical and acceptable manner but not

Not only are they left out of the Register and American Medical Directory but their names are consistently omitted from all the publications of the Association and they are refused admission to the advertising columns.

This helps to distinguish between the good and the bad in hospitals. As a result, it is considered a disgrace among hospitals and physicians to be refused registration, and institutions that are rejected are frequently aroused and correct the objectionable practices in order that they may be recognized. Public and professional opinion forces many such institutions to sell their buildings to more reputable owners or to close up.

The Register is used as a basic list of hospitals. Industrial and governmental agencies use it in selecting hospitalization for their dependents and beneficiaries. Physicians almost universally observe the Register in referring their patients.

The good work that the American Medical Association has accomplished by its vigilance in distinguishing between the fit and the unfit in the hospital field has been shared very largely by other organizations. The American College of Surgeons has cooperated by refusing to consider for its approval an unregistered hospital, and the American Hospital Association has followed the Register in considering applications for institutional membership. It is evident also that the public in general limits its patronage and its donations to hospitals that are considered worthy of a place in the Register.

Opportunity is always open to unregistered hospitals to mend their ways and merit registration.

DEVELOPMENTS IN INTERN TRAINING

Two criticisms directed at the internship period have been subjected to pointed inquiry recently. These are (1) that, as now constituted, the internship period concentrates interest more particularly on the end results of disease rather than on early recognition and treatment, (2) that interns, since they are not in position to translate present experience in terms of future usefulness, are inclined to slight the commonplace in complaints and procedures and to waste time and effort in the pursuit of the unessential, the unusual or the spectacular.

Our knowledge of educational programs in general hospitals indicates that these indictments are too commonly true. It is equally true that most institutions lend themselves to teaching young medical graduates according to accepted standards only after the expenditure of considerable thought and effort. Much reliance has been placed on the personal initiative of interns to translate a mediocre internship into a well-rounded useful service. Such individual industry and application are admittedly indispensable factors in any good internship, but the criticisms mentioned lead one to believe that dependence on this factor is not enough.

Proper use of outpatient material answers the criticism relating to contact with early manifestations of disease and it is pointed out that affiliations are available in most communities for such experience. In this way, interns can observe and manage mental and communicable diseases and attend antepartum, pediatric, metabolic, venereal and other types of clinics. In several instances, use has been made of ambulatory patients in doctors' offices.

There has always been a considerable waste of the many opportunities for experience in commonplace procedures available in most hospitals. The Report of the Commission on Medical Education was largely responsible for focusing attention on the principal demands made on general practitioners. As a result, practical aspects of hospital service useful to practitioners are beginning to receive the attention they deserve. Commentators frequently have noted the ignorance of recent medical graduates in the simplest nursing procedures and the gratitude of the house staff after such demonstrations have been arranged. Similarly, instruction in the dietetic laboratory, pharmacy, physical therapy department and other hospital units has proved extremely useful. Greater emphasis on minor surgery, fractures, infant feeding, conservative obstetrics, anesthesia and the like has been discussed in previous hospital numbers of *THE JOURNAL*. Likewise, training of interns in nonclinical subjects, such as medical organization, economics, jurisprudence, insurance and compensation laws has been inaugurated in

many hospitals by development of seminars conducted by the interns themselves.

Hospitals in many instances attract interns through the merits of outstanding clinicians or services. Evidences of thoughtfully considered, complete internship programs are, however, no longer uncommon. In every such instance, progress in intern training in individual institutions is in direct proportion to the alertness of the staff intern committee.

AVAILABLE CLINICAL MATERIAL

The attention of hospitals has been called to the change in the Council's requirements covering available clinical material in hospitals seeking internship approval. This regulation now reads: "General hospitals are eligible which admit at least 2000 patients per year and/or have a daily average census of seventy-five patients, and which provide a variety of medical, surgical, obstetric and pediatric patients either in the hospital proper or through suitable affiliations with other institutions. New-born infants are included in computing the daily average census but are not counted as admissions. Deviations from this rule are occasionally permitted by the Council but only on the basis of individual investigation. Allowances are occasionally made for additional sources of patients such as an active, organized outpatient department or affiliation with other special institutions."

A change of even greater significance has been the abandonment of the beds per intern ratio as a reliable index to diversification and availability of clinical material. A recent study indicates that a much more satisfactory index rests on the number of admissions per intern annually. It has been found that the best teaching hospitals employ one intern for each 430 yearly admissions, which means that each intern is responsible for a complete workup on slightly more than one admission daily. In the opposite sense it is thought that an intern cannot be expected to make adequate routine investigations on more than two patients a day, which places the maximum yearly admission rate per intern at about 700. Since the average length of stay in general hospitals is in the neighborhood of ten days and with the preceding ratios in mind, it follows that the total number of inpatients per day over which an intern should assume responsibility lies between the limits of ten and twenty.

If these ratios are accepted as adequate indexes, it can be foreseen that in time hospitals will, as a general rule, be expected to develop a program for at least four interns. If for any reason fewer are employed, special precautions would be necessary to prevent spreading intern effort over too wide a field.

It should also be borne in mind that logically these proportions should be applied to clinical material in each of the larger clinical departments—medicine, surgery, obstetrics and pediatrics. Preponderance of admissions in one department would not under this arrangement compensate for scarcity in another.

RESIDENCY APPROVAL

There is widespread interest at the present time in residency approval, a circumstance following closely on the development of special examining boards. It is hoped that the Council may secure assistance and cooperation from these boards in the further development of the hospital as an integral part of postgraduate training in medicine and in the elaboration of standards which will assist in the evaluation of hospital training in each of the residency classifications.

HOSPITALS REGISTERED BY THE AMERICAN MEDICAL ASSOCIATION

The following list contains the names of 6,246 hospitals, sanatoriums and related institutions that are located in the United States and 233 in Alaska, Canal Zone, Guam, Hawaii, Philippine Islands, Puerto Rico and Virgin Islands. It omits the names of 564 hospitals which, after investigation, were not accepted. The inclusion of the name of any institution may be taken as an indication that evidence concerning irregular or unsafe practices in that institution has not come to the attention of the Council on Medical Education and Hospitals. The list in each state is given in two sections: (1) hospitals and sanatoriums, and (2) related institutions. The related institutions include some general hospitals lacking certain essentials, nursing homes, school infirmaries, prison infirmaries, custodial and other institutions designed to give some medical, nursing or convalescent care in an ethical and acceptable manner, but not strictly hospitals. In the statistics the two classifications are consolidated. The words "No data supplied" following the name of a hospital mean that no report was received although at least three requests were sent.

KEY TO SYMBOLS AND ABBREVIATIONS

- * Approved for general internship the fifth year in medicine by the Council on Medical Education and Hospitals
- + Approved for certain residencies in specialties for graduates in medicine who have already had a general internship or its equivalent in private practice

- ◇ School of nursing accredited by state board of nurse examiners
- Affiliated for nurse training on state accredited basis

The column headed "Type of Service" tells what diseases or conditions are treated in each institution, as follows:

Ca	Cancer	ENT	Eye ear nose and throat	Inst	Institutional	Orth	Orthopedic

The column headed "Control" indicates for each institution the ownership, control, or auspices under which it is conducted, as follows:

GOVERNMENTAL		NONPROFIT ORGANIZATIONS		PROPRIETARY	
Federal	State	Church	Individual	Individual	
Indian Affairs	City	Fraternal	Partnership	Partnership	
United States Army	County	Nonprofit association	Corporation	Corporation	
United States Navy	City County		(unrestricted as to profit)		
United States Public Health Service					
Veterans Administration Facility					

ABBREVIATIONS

CyCo	City and county	Frat	Fraternal	NPAsn	Nonprofit association
Corp	Corporation unrestricted	IA	Office of Indian Affairs	Part	Partnership
	as to profit		Department of the Interior	USPHS	United States Public Health Service
Fed	Federal	Indiv	Individual	Vet	Veterans Administration Facility

Population of cities is based on the 1930 census of the United States Bureau of the Census. Consultation with the Bureau led to this decision. Population of states is based on estimates of the Bureau as of July 1934.

The accompanying list was subject to additions and removals of hospitals until going to press. Totals of the list therefore may vary slightly from tables 1 and 2 which were prepared as of Dec 31, 1935.

HOSPITAL SERVICE FOR THE AMERICAN PEOPLE

The fifteenth annual presentation of hospital data in this issue of *THE JOURNAL* provides facts about hospital service. Returns have come from 96 per cent of all the registered hospitals in the United States, representing around 99 per cent of the bed capacity. Appreciation is here tendered to hospital superintendents and other officials, to members of staffs and to officials of county and state medical societies and others who have made the annual census successful.

Hospitals have made an average gain of more than 25,000 beds a year for twenty-six years. Over 7,700,000 persons, not including new-born infants, were admitted as bed patients during 1935. Ninety per cent of all admissions were in general hospitals. Three fourths of the 200,000 idle beds in the country are in general hospitals. Confronted with these figures, all of which are conservative, can any one doubt the importance of the hospital as an adjunct to the practice of medicine? Will any one fail to see the significance of 769,660 babies born in the hospitals and a total of 320,000,000 patient days during the year? The operation of hospitals is one of America's major enterprises.

The three divisions or types of organizations controlling hospitals are nonprofit organizations, organizations for profit, and governmental agencies. The patronage of the nonprofit hospitals although charging full or part cost when feasible and usually not subsidized increased 75 per cent during the year 1935 as against an increase of 27 per cent in county and city hospitals and in proprietary hospitals and 58 per cent in governmental hospitals. The nonprofit organizations cared for nearly 60 per cent of all patients admitted to hospitals, the remaining 40 per cent going to governmental agencies and organizations for profit. Nonprofit hospitals, numbering 2,640, are composed mainly of general hospitals distributed over the entire country and each serving a more or less definite community. To this group go most of the acute cases of sickness and injury. Most of them are general hospitals. They

accommodate the private patients of a majority of physicians. They are training places for most of the resident physicians, interns, medical students and nurses. These organizations therefore deserve support from the public, the profession and philanthropists. The nonprofit voluntary organization, whether independent corporation, church or other type of nonprofit association, must continue, increase and improve, with the support of the whole people.

The development of hospitals as educational institutions is introducing new problems into hospital administration and control. Occasionally public hospitals are exploited as institutions for postgraduate study without any attempt to demand adequate fundamental training or certification of prerequisite knowledge of those who take the postgraduate study. Hospital administrators must determine whether or not their main educational function is education of the undergraduate, education of the intern or postgraduate training. Moreover, the rights of the patient are paramount to any educational function.

IVAN PETROVITCH PAVLOV

On February 27 Prof Ivan Petrovitch Pavlov died at the age of 87 years. Dr Pavlov was the most prominent character in science and medicine in Russia of the past generation. In his passing the medical profession of the world mourns the loss of a congenial and brilliant colleague, whose contributions to scientific medicine will ever be a cherished heritage.

Son of a Russian priest, educated in the schools of Leningrad, he early betook himself to the laboratories of the leaders of physiologic research in Germany, the workshops of Ludwig and Heidenham. In the laboratory of Heidenham, Pavlov received the stimulus to research on the function of the alimentary canal. His contributions, particularly on the role of the nervous system in gastric and pancreatic functions, were of great significance. This work gained him the Nobel prize in physiology and medicine in 1904.¹ The essentials of Pavlov's investigations in this field have stood the test of time and the results stand as a milestone in this field of physiology and medicine.

During the last thirty years Pavlov was engaged in developing a new method of investigation of the central nervous system, the method of "conditioned reflexes."² Conditioned reflexes differ from the inherited reflexes in the sense that the former are the sequelae of individual experience. Following the lead of Pavlov, investigators have employed the conditioned reflex method extensively in the study of learning in all types of animals, from fishes to man. The method appears applicable in earliest childhood as well as in various conditions of the disturbances of the central nervous system in man and in animals. The possibility of this

¹ The Work of the Digestive Glands translated by W. H. Thomson 1902

² Conditioned Reflexes translated by Prof. A. N. S. P. Oxford University Press 1927

method in the analysis of disorders of the central nervous system in man still lies mainly before us. As in the case of Pavlov's work on the digestive glands, the essentials of his contributions by the method of conditioned reflexes have stood the test of repetition. Of course, many facts and many interpretations have been challenged by other workers and require further study.

Professor Pavlov twice visited this country first in 1923, and again at the meeting of the International Congress of Physiologists in Boston ten years ago. In the winter of 1935 he had a severe attack of pneumonia but recovered and was able to take part in the International Neurological Congress in London last July. He was president of the International Physiological Congress meeting in Leningrad and Moscow last August. At this congress he was given many tokens of high honor and personal regard by his fellow countrymen³ and the thousand colleagues from other parts of the world. The present generation of physiologists and medical investigators in Russia is made up mainly of the pupils of Pavlov.

Professor Pavlov was a man of tremendous industry and enthusiasm in medical research, in poverty and in prosperity, fearless and uncompromising, but, with all, displaying the true democracy of science. He could laugh at his own folly as well as at the folly of his fellow men. He was deeply troubled by the misfortunes of his colleagues in his own and other countries in the present generation.

SURGEON GENERAL HUGH S. CUMMING RETIRES

On January 28 President Franklin D. Roosevelt sent the following letter to Surgeon General Hugh S. Cumming of the United States Public Health Service:

It was with great regret that I learned that the state of your health would no longer permit you to bear the heavy strain of your work as Surgeon General of the Public Health Service and that Secretary Morgenthau had therefore given approval to the findings of a medical board convened at your request, which recommended that you be placed on waiting orders as of February first.

Your release from active duty marks the rounding out of a career in the public service which the American people can view with pride and admiration because of the honor you have brought to them as their faithful servant and benefactor. You yourself may view it with the most thorough satisfaction in a task well done.

I am happy to recall that your labors in protecting humanity against disease and in advancing health standards everywhere have brought you deserved recognition and honor not only in your own country but throughout the world.

I am privileged to express to you the gratitude of the Nation and to add my own thanks for the great service you have rendered.

The action followed the report of a board of medical officers, which indicated that the physical condition of Dr. Cumming no longer permitted him to bear the heavy burdens of his office. The announcement of his

retirement brought messages of appreciation of his services from leaders in statesmanship and in public health throughout the world.

Dr. Cumming was the fifth Surgeon General of the United States Public Health Service. He was born Aug. 17, 1869, at Hampton, Va., and, after graduation in medicine from the University of Virginia in 1893, entered the Public Health Service as assistant surgeon in 1894. Between that time and February 1920, when he was first appointed Surgeon General, he served notably at Ellis Island in San Francisco and abroad, acquiring extended knowledge of the medical aspects of the immigration question and also intimate knowledge of the details of public health and sanitation. During the World War he was detailed to the Navy as adviser in sanitation and later served in Europe as president of the interallied sanitary commission to Poland. He has represented the United States in innumerable foreign conferences on health matters and is a member of the permanent committee of the Office international d'hygiène publique, and of the health committee of the League of Nations. His distinguished career has been recognized by the decorations of Commander of the Legion of Honor of France, Commander Poland Restituta of Poland, Order Al Merito of Ecuador, Order of Carlos Finlay of Cuba, and Order of El Sol of Peru.

Space does not permit a listing of the unusual accomplishments of the United States Public Health Service during Dr. Cumming's administration. It is important to realize, however, that he was renominated to office by each succeeding President since 1920 and that his entire term of service embraces forty-two years, during sixteen of which he was Surgeon General.

The work of the Surgeon General of the United States Public Health Service gives him control of a department that must ever be in intimate contact with the medical profession. As a leader of that service Dr. Cumming showed always a sympathetic insight into the problems of the practicing physician and an earnest desire to be of the utmost assistance in working out those problems, so as to maintain the high quality of medical service rendered to the people by the American medical profession. In his appearances before numerous governmental commissions and legislative bodies he spoke always in behalf of the highest ideals. He recognized, however, the great responsibility which the medical profession bears to the public in rendering its service. Thus he said in concluding one of his best addresses on this subject:

From time immemorial the medical profession has been regarded as the natural sponsor not only of individual but also of community health. Legal provisions relating to standards of medical education and privilege of the practice of medicine rest on this foundation. Whether this service in future shall be rendered by the profession in cooperation with health authorities or be made incumbent on the legal health representatives must depend on the character of the service rendered by the profession. It should be the object of the organized profession to impress on each individual physician his responsibility in this matter.

³The Russian government had built a splendid new research laboratory and a comfortable home for Pavlov on a charming country site a few miles out of Leningrad.

Dr Hugh S Cumming retired on January 31, leaving for what should be a long and happy period of recreation following his arduous and distinguished work

Current Comment

PROGRESS IN TRAINING OF INTERNS

The hospital internship has long been an accepted institution. Nearly every graduate takes a year or more of intern training whether it is required or not. The internship essentially is an educational experience. It is the fifth year in the study of medicine. The intern in his four years in medical school has been subject to a routine of class work, laboratory and the lecture room, with periodic examinations. In his fifth year, educational responsibility is shifted to the hospital. It is still an educational year. The hospital now assumes the role of an educational institution—a school. Staff physicians are the teachers. The patient-physician-intern relationship should prove a benefit to each member of the trio and to the hospital management as well. The hospital field has been covered by visits of inspection. Much study has been made of best methods and traditions in the training of interns. Much aid has been given, particularly to the newer and smaller hospitals that train interns, with the result that there are now 708 hospitals approved for intern training, each being marked by a star in the list of registered hospitals appearing in this issue. These furnish a total of about 6,500 approved internships. Interest in intern training is greater now than at any time since the Council published its first approved list in 1914. In addition to the Council's activities, the internship is receiving special attention and study in both large and small centers. The special study of approved internships in New York City is described in one of the contributed articles of this issue. During the present year the Council on Medical Education and Hospitals will pursue its study of the internships with increased zeal, and its staff of examiners expects to revisit not less than 500 hospitals approved for internship.

RESIDENCIES IN SPECIALTIES

One or more educational years of hospital experience following the internship is becoming more and more common. The increased use of hospitals for medical practice makes more hospital jobs for physicians. There is increasing desire for more experience and greater skill before entering independent practice. To help both the hospitals and young graduates, the Council has developed a list of hospitals approved for residencies in specialties. This was first issued in 1927 with 270 hospitals and 1,699 residencies. In the list of hospitals appearing elsewhere in this issue there are 405 hospitals approved for residencies in specialties, indicated by a plus sign. They provide for 2,600 residencies. A residency in a hospital is not of itself

preparation for the practice of a specialty. It may be a proper step in that direction. Whether the erstwhile intern pursues additional hospital years as further preparation for general practice or as a step toward specialization, each year of additional service in an approved hospital is credited in the biographic file of the American Medical Association. Approved internships are likewise credited. Residencies in specialties are of special importance at this time, when certification of specialists is being rapidly developed through the formation of special examining boards, which will determine by an examination the fitness of the candidate to practice his specialty. The public and the profession may then know by turning to the American Medical Directory or other sources of information physicians who have been found to qualify in the practice of their specialty. Ten boards have already been formed and two additional ones are in the making. Five boards have been approved by the Council on Medical Education and Hospitals, one has been tentatively approved and three additional ones have applied. The combined efforts of these boards, the staffs of teaching hospitals, the Council and others will be required to develop residencies that will give the training needed toward meriting the qualifying certificate of a specialty examining board.

Association News

ABSTRACT OF MINUTES OF MEETING OF BOARD OF TRUSTEES HELD AT THE PALMER HOUSE, IN CHICAGO, FEB 20 AND 21, 1936

LEGISLATION

The Board went on record as offering no objection to the principles embodied in bill H R 10586 to provide for the more adequate protection of the revenue, a more effective enforcement of the revenue and other laws administered by the Treasury Department and for other purposes, with the understanding that the consolidation proposed in the amended bill would maintain the integrity of the Bureau of Narcotics and the functions of the Commissioner of Narcotics in an independent unit and that the medical profession would not be placed under the direct surveillance of the Secret Service Division of the Treasury Department as such.

S 3744 and its companion bill H R 10385, to amend the act creating the Federal Trade Commission, to define its powers and duties and for other purposes, the purpose of which is to enlarge the powers and the authority of the Federal Trade Commission, was approved.

Concerning H J Res 449, which proposes to authorize the Secretary of Labor to appoint a board of inquiry to make a prompt and thorough investigation of all facts relating to health conditions of workers employed in the construction and maintenance of public utilities, the Board voted to endorse action that will limit the study of problems in regard to industrial medicine to the United States Public Health Service and medical agencies.

It opposed H R 10632 to amend the act entitled "An Act to amend and consolidate the Acts respecting copyright," which would divest the publisher of control of copyrights and vest them in the author."

REQUESTS FOR SPECIAL SESSION OF HOUSE OF DELEGATES

Consideration was given to requests for the calling of a special session of the House of Delegates, even though they were not made as prescribed by the By-Laws, and in view of

the fact that the Kansas City Session is imminent, being less than ten weeks away, the Board deemed it inexpedient to call a special session prior to that time

INVITATION TO SEND REPRESENTATIVES TO MEETING
OF BRITISH MEDICAL ASSOCIATION

The Board voted to accept the invitation from the British Medical Association to send representatives to its meeting to be held in Oxford, July 21-24

APPROPRIATIONS

Appropriations were made for the conduct of the work of the several councils, bureaus and committees as well as for the continuance of scientific and therapeutic research, also for the purchase of presses and other machinery to replace equipment that is worn out and to provide additional much needed facilities for handling the work in the headquarters office

PARTICIPATION IN EXPOSITION IN SAN DIEGO,
CALIF., AND IN DALLAS TEXAS

The Board approved of the preparation of exhibits by the Bureau of Educational and Scientific Exhibits for the expositions in San Diego and Dallas

DR FRANK J CLANCY SUCCEEDS DR ARTHUR J CRAMP
AS DIRECTOR OF BUREAU OF INVESTIGATION

Approval was given to the employment of Dr Frank J Clancy of Seattle as director of the Bureau of Investigation, to succeed Dr Arthur J Cramp, who retired November 1 because of ill health

ELECTIONS

To fill vacancies caused by expiration of terms, resignations and deaths, the following appointments were made: Council on Pharmacy and Chemistry—Dr Torald Sollmann to succeed himself, Dr W C Rose, Urbana, Ill to succeed Dr Lafayette B Mendel (deceased), and Dr E M K Geiling, Baltimore, to succeed Dr Reid Hunt (resigned). No appointment was made to fill Dr L G Rowntree's place at present, it being decided that the work of the Council could be conducted with one less member. Council on Physical Therapy—Drs Robert B Osgood, F J Gaenslen and Howard T Karsner to succeed themselves. Committee on Foods—Dr Russell M Wilder to succeed himself, and Dr Martha Eliot, Washington, D C, to succeed Dr Lafayette B Mendel (deceased). To expedite work of this committee, it was decided to make its secretary a member of the committee. *Archives of Internal Medicine*—Dr Arthur Bloomfield, *Archives of Ophthalmology*—Dr Arnold Knapp, *Archives of Neurology and Psychiatry*—Dr H Douglas Singer, *Archives of Otolaryngology*—Dr Ralph A Gerton, *Archives of Pathology*—Dr Frank R Menne—all to succeed themselves. *Archives of Dermatology and Syphilology*—Dr Howard Fox of New York to succeed Dr Charles J White. *Archives of Surgery*—Dr William Darrach to succeed himself, and Dr Waltman Walters, Rochester, Minn, to succeed Dr E Starr Judd (deceased). Committee for the Protection of Medical Research—Drs Lewis H Weed and Walter Cannon to succeed themselves. Committee on Scientific Research—Dr Ludwig Hektoen to succeed himself.

The resignation of Dr Victor C Jacobsen from the editorial board of the *Archives of Pathology* was received and it was decided not to fill his place

MISCELLANEOUS BUSINESS

Numerous other matters received careful attention, and many of these will be reported on at a later date

RADIO BROADCASTS

The American Medical Association broadcasts over WEAF the Red network instead of the Blue as formerly and certain additional stations of the National Broadcasting Company at 5 p m eastern standard time (4 o'clock central standard time, 3 o'clock mountain time 2 o'clock Pacific time) each Tuesday, presenting a dramatized program with incidental music under the general theme of Medical Emergencies and How They Are Met. The title of the program is Your Health. The program is recognizable by a musical salutation through which the voice of the announcer offers the toast 'Ladies and gentlemen your health'. The theme of the program is repeated each week in the opening announcement which informs the listener

that the same medical knowledge and the same doctors that are mobilized for the meeting of grave medical emergencies are available in every community, day and night for the promotion of the health of the people. Each program will include a brief talk dealing with the central theme of the individual broadcast

Red Network—The stations on the Red network of the National Broadcasting Company are WEA, WEEL, WTIC, WJAR, WTAG, WCSH, KYW, WFBR, WRC, WGY, WBEN, WCAE, WTAM, WWJ, WMAQ, KSD, WHO, WOW, WDAF

Pacific Network—The stations on the Pacific network are KGO, KPO, KFI, KGW, KOMO, KHQ, KFSD, KTAR

Network programs are broadcast locally or rejected at the discretion of the local station. The lists indicate stations to which programs are available

The next three programs are as follows

March 10 Hard of Hearing Morris Fishbein M D
March 17 Eyesight Saving W W Bauer M D
March 24 Hay Fever and Asthma Morris Fishbein M D

CALIFORNIA

Society News—Dr Hans Lissner, San Francisco, addressed a joint meeting of the Los Angeles Society of Neurology and Psychiatry and the Endocrine Study Club of Los Angeles, February 19, on "Adrenal Cortical Syndromes with a Consideration of Cushing's Disease and Arrhenoblastoma."—At a meeting of the Los Angeles Society of Ophthalmology and Otolaryngology, February 18, Dr Harry S Gradle, Chicago, discussed "Surgery of Retinal Detachment. End Results of Various Methods."

COLORADO

Society News—The Larimer County Medical Society was addressed in January in Fort Collins by Drs Roy P Forbes and Osgood S Philpott, Denver, on "Common Errors Made in Pediatric Diagnosis" and "Commonly Missed Dermatologic Diagnoses," respectively.—At a meeting of the Northeast Colorado Medical Society, January 29, a symposium on cancer of the female genital tract was presented by Drs Lyman W Mason, Sanford M Withers and Charles B Kingry, Denver.—Dr Henry M Powell, Colorado Springs, addressed a joint meeting of the El Paso County Medical Society and the staffs of the various hospitals in Colorado Springs January 15, on peptic ulcer.

GEORGIA

Health at Atlanta—Telegraphic reports to the U S Department of Commerce from eighty-six cities with a total population of 37 million, for the week ended February 22, indicate that the highest mortality rate (24.4) appears for Atlanta and the rate for the group of cities as a whole, 14. The mortality rate for Atlanta for the corresponding period last year was 16.8 and for the group of cities, 12.1. The annual rate for eighty-six cities for the eight weeks of 1936 was 13.5 as against a rate of 12.9 for the corresponding period of the previous year. Caution should be used in the interpretation of these weekly figures as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate.

ILLINOIS

Society News—Dr Martin F Engman, St Louis, discussed the subject of eczema before the Madison County Medical Society, Granite City, February 7.—At a meeting of the Kankakee County Medical Society in Kankakee, February 20, Dr Kellogg Speed, Chicago, discussed skull fractures.—Dr Leon Unger, Chicago, among others, addressed the Will Grundy Medical Society, February 19, on "Recent Advances in the Study of Allergic Conditions."—Dr Isaac A Abt, Chicago, discussed "Management of the Infant During the First Three Months of Life" before the Decatur Medical Society, February 18.

Chicago

Correction—Clinical Meeting—The Institute of Traumatic Surgery will hold an all day clinical session at St Luke's Hospital, March 13, instead of March 15, as announced in THE JOURNAL, February 29

Lectures on Mental Hygiene—The Illinois Society for Mental Hygiene is sponsoring a series of lectures at Fullerton Hall, Art Institute. Dr Charles F Read, Elgin gave the first in the series February 19, on 'Modern Hospital Care of the Mentally Ill,' Dr Abraham A Low, the second, February 26, 'A Common Form of Mental Disease Dementia Praecox (Schizophrenia),' and Dr Low, the third March 4 'A Common Form of Mental Disease Manic-Depressive Psychosis' Other speakers will be

Dr David B Rotman March 11 Mental Illness in Old Age

Dr Fred Temple Burling March 18 Nervousness

Dr Rotman March 25 Alcohol and Mental Disease

Society News—The Chicago Medical Society was addressed, March 4, by Drs Ralph M Waters, Madison, Wis., and John S Lundy Rochester Minn., on anesthesia—At a meeting of the Chicago Society of Internal Medicine, February 24 Dr Edmund Jacobson among others, spoke on 'The Influence of Skeletal Muscle Tension on Blood Pressure'—Dr Russell D Herrold discussed 'Environmental Altered Gonococcal Forms and the Probable Mechanism of Cure in Gonorrhea' among other speakers before the Chicago Urological Society February 27—The Chicago Laryngological and Otolological Society was addressed March 2 by Dr Louis Z Fishman on 'Bilateral Spastic Adductor or Flaccid Abductor Paralysis of the Larynx—Experimental Interpretation,' and Clarence Simon, Ph D professor of speech reeducation, Northwestern University, 'Functional Disorders of Speech and Their Correction'—Dr Earl R Carlson, New York, addressed a joint meeting of the Jane A Neil Club and the Chicago Orthopaedic Society, March 4, on 'Treatment of the Spastic Child'

IOWA

Physician Honored—Dr Jennie May Coleman received the Des Moines Tribune community service cup for 1935 at a ceremony, February 14 The ceremony was broadcast over radio station KSO with Basil L Walters, managing editor of the Register and Tribune introducing Dr Coleman The physician is 67 years of age and a graduate of the State University of Iowa College of Homeopathic Medicine, class of 1898

Society News—Dr Carlo S Scuderi Chicago, addressed the Scott County Medical Society, January 7 in Davenport on 'Injuries of the Vertebral Column'—Dr Charles A Elhott Chicago, discussed 'Management of Hepatic Disease' before the Woodbury County Medical Society in Sioux City, January 8—Dr Irving F Stein, Chicago addressed a joint meeting of the Grimes Study Club and Des Moines Academy of Medicine in Des Moines, January 25 on 'Gynecologic Diagnosis with the Aid of Pneumoroentgenography and Hysterosalpingography', in the morning Dr Stein conducted a clinic

KENTUCKY

Society News—Dr Frank M Stites Jr, Louisville, addressed the Christian County Medical Society Hopkinsville, January 21, on hypertensive heart disease—Speakers at a meeting of the Bourbon County Medical Society, Paris January 16 were Drs Arthur B Barrett, Lexington on 'Significance of Pulse, Temperature and Blood Pressure in Obstetric Complications' Eugene H Hyden Auer, 'Inhibition in Prostatic Hypertrophy,' and Eugene L D Blake, Paris 'Significance of Sedimentation Tests'—A symposium on treatment of peptic ulcer was presented at a meeting of the Jefferson County Medical Society, Louisville February 17 by Drs Chauncey W Dowden Frank A Simon and Irvin Abell Speakers in a symposium on hypertension February 3 were Drs Woodford B Troutman Frank M Stites Jr Frank W Pirkey, Louisville and Garland L Dyer, Buechel

MARYLAND

Dr Williams Honored—A testimonial dinner was given in honor of Dr Huntington Williams health commissioner of Baltimore January 22, by more than 200 Baltimore physicians and officers of the Baltimore Association of Commerce at the Southern Hotel Dr John M T Finney professor emeritus of surgery, Johns Hopkins University School of Medicine was toastmaster Speakers at the dinner included Mayor Jackson Drs Thomas S Cullen who was honorary chairman Charles C W Judd Allen W Freeman Baltimore and Reginald M Atwater New York secretary of the American Public Health Association Dr Williams has been commissioner of health of Baltimore since 1932, when he succeeded the late Dr C Hamp-

son Jones The previous year he resigned as secretary of the New York State Department of Health Albany, to become director of health of Baltimore

MASSACHUSETTS

Bills Introduced—H 1097, to amend the dental practice act, proposes to prohibit registered dentists and dental hygienists from advertising "in any newspaper or by radio, display sign or by means of show cases, containing the representation of a tooth, teeth, dental restoration of any kind or of whatsoever design or description of any portion of the human head or neck or photograph of any person, in any other manner whatsoever" H 1528, to amend those provisions of the medical practice act relating to the educational qualifications of applicants, proposes (1) to require applicants to possess the educational qualifications required for graduation from a public high school, (2) to have attended courses of instruction for four years of not less than thirty-two school weeks in each year, or course which, in the opinion of the board, are equivalent thereto, in one or more legally chartered medical schools and (3) to have received the degree of doctor of medicine or its equivalent from legally chartered medical schools having the power to confer degrees in medicine and, if chartered under the laws of any other state than Massachusetts, approved by the board

MICHIGAN

Arts and Craft Exhibition—The third annual exhibit of arts and crafts under the auspices of the art committee of the woman's auxiliary to the Wayne County Medical Society will be held March 8-13 Physicians and members of their families are eligible to exhibit their work

MINNESOTA

Dr Lyon Will Retire as Dean—Dr Elias P Lyon, since 1913 professor of physiology and dean of the University of Minnesota School of Medicine, will retire from the faculty June 30 Dr Lyon, who is 68 years of age, received the honorary degree of doctor of medicine from St Louis University in 1910 He taught at Hillsdale College, Harvard School Chicago, and Bradley Polytechnic Institute, Peoria, Ill He became assistant professor at Rush Medical College in 1900 This position he held until 1904, carrying concurrent appointments of assistant professor of physiology and assistant dean of the University of Chicago from 1901 to 1904 He was professor of physiology at St Louis University School of Medicine from 1904 to 1913 and dean from 1907 to 1913 In the latter year he went to the University of Minnesota School of Medicine a professor of physiology and dean Dr Lyon was president of the Association of American Medical Colleges in 1913

MISSISSIPPI

Society News—At a meeting of the Coahoma County Medical Society and the staff of Clarksdale Hospital in Clarksdale January 8, Dr William H Brandon, Clarksdale, discussed hypotension, among other speakers—Dr Guy C Jarrett Vicksburg, read a paper before the Homochitto Valley Medical Society in Natchez, January 8, entitled 'Pyuria in Children'—Among others, Dr James S McLester, Birmingham, Ala President, American Medical Association addressed the North Mississippi Medical Society January 15 in New Albany, on 'Deficiency Syndrome in America'—The Isaquena-Sharkey-Warren Counties Medical Society devoted its meeting, January 14 to a discussion of medical economic speakers were Drs Winston C Pool and Henry S Goodman Cary, and William K Purks, Willard H Parsons, Leon C Lippincott and Edley H Jones all of Vicksburg

MISSOURI

Dr Cannon Gives First Loeb Lecture—Dr Walter B Cannon George Higginson professor of physiology, Harvard Medical School Boston delivered the first Leo Loeb Lecture at Washington University School of Medicine March 2 His address was entitled 'Some Adventures in Discovery'

Society News—A joint meeting of the Jackson and Wyanotte County medical societies in Kansas City was addressed February 11 by Dr Wheelan D Suthiff Chicago, who discussed Cases of Pneumococcus Infection Illustrating Pneumothorax Therapy Oxygen Therapy and the Spontaneous Development of Immunity—A symposium on urologic diagnosis was presented before the St Louis Medical Society February 11 by Drs John F Patton, James M Macmillan, Elmer E Sexton and James A O Dowd Speakers February 4 were Drs Vilray P Blair and Duff S Allen on 'Peridontal Infections and Lateral Aberrant Thyroid' respectively

NEW JERSEY

Bill Introduced—A 416, to amend the laws relating to the practice of the healing art, proposes to require the board of medical examiners to issue a license to practice osteopathy to any licensed chiropractor in New Jersey who possesses an unrevoked license to practice osteopathy in another state or in the District of Columbia. The scope of the license to practice osteopathy to be issued to such a practitioner is to be equivalent to the scope of the license to practice osteopathy on the basis of which his license to practice osteopathy in New Jersey is issued.

NEW YORK

Bills Introduced—S 1063, to amend the medical practice act, proposes that notwithstanding any other provisions of that act, a graduate of a medical school or college registered and maintaining at the time a standing satisfactory to the education department, who has been licensed in a foreign state or country on written examination, may have his foreign license endorsed without examination and be licensed to practice medicine in New York. S 1065, to amend the medical practice act, proposes to make it a ground for the revocation of a license for a physician to advertise for patronage by means of handbills, posters, circulars, letters, stereopticon slides, motion pictures, radio or newspapers. S 1083 and A 1356 propose to appropriate \$100,000 to the department of labor to be used for the prevention of silicosis and other dust diseases. S 1084 and A 1355, to amend the workmen's compensation act, propose to restrict, within the limits set out in the bill, the compensation and medical treatment for which an employer is liable under that act, to a worker partially or totally disabled from silicosis or other dust diseases. A 1445 proposes that the provisions of the pharmacy practice act shall not apply to the manufacture of proprietary medicines except such as are poisonous, deleterious and/or habit forming.

New York City

Society News—Dr Alexander W. Jacobs addressed the Bronx Gynecological and Obstetrical Society, February 24, on "Radiation Therapy in Gynecology." Drs Louis J. Ferrara and Joseph Lozner addressed the Bronx Pathological Society, February 18, on "Present Concept of Jaundice."—At a meeting of the International Spanish Speaking Association of Physicians, Dentists and Pharmacists, February 21, a program of surgical, medical and dental motion picture films was presented. Dr Jacob M. Gershberg was recently reelected president of this association.—Speakers before the Medical Society of the County of Queens, February 25, were Drs Charles C. Wolferth, Philadelphia, on "The Present Status of Electrocardiography in the Study of Coronary Arteriosclerosis and Its Complications," Irving R. Roth, "Prognosis of the Various Types of Heart Disease," and Daniel Porte, "Newer Methods of Treatment of Diseases of the Heart." Dr Benjamin Koven gave the society's Friday afternoon lecture March 6 on "Painful Feet."—Dr William P. Murphy, Boston, addressed the National Society for the Advancement of Gastro-Enterology, February 25, presenting "An Analysis of the Complications in a Series of Patients with Pernicious Anemia with Special Consideration of the Digestive System," and Dr Leon Schiff, Cincinnati, on "Jaundice."—Dr George W. Crile, Cleveland, addressed the New York Cardiological Society, February 26 on "The Genesis and Operative Treatment of Essential Hypertension."—Drs Leo M. Davidoff and Raphael Kurzrok addressed the New York Endocrinological Society, February 26 on "Pituitary Tumors" and "Clinical Value of Sex Hormone Tests, respectively."—Dr Percy Klingenstein addressed the New York Surgical Society, February 26, on "Problems in the Surgical Management of Gastric Ulcer."

NORTH CAROLINA

University News—Dr Alfred Blalock, Nashville, Tenn., delivered lectures on "Shock and Lymphatic Obstruction" at Duke University School of Medicine January 30-31. Dr Charles L. Strosnider, Goldsboro, president-elect of the Medical Society of North Carolina, spoke, January 23 on "Organized Medicine and Medical Ethics."

OHIO

Dr Huston Honored—The Montgomery County Medical Society gave a dinner at the Biltmore Hotel, Dayton, January 24 in honor of Dr Edwin M. Huston, Dayton, president-elect of the Ohio State Medical Association. Dr Harold F. Koppe, president of the county society, presided and speakers were Drs. Huston, Clud N. Chrisman and Walter M. Simpson. Flowers and a volume containing signatures of the guests were presented to Dr Huston.

PENNSYLVANIA

Personal—Dr Francis S. Chambers has resigned as chief surgeon of the State Hospital for Crippled Children, Elizabethtown, it is reported.—Dr David Moore Davis, Broughton, was honored by a testimonial dinner given by the community, January 28, in recognition of his thirty-five years of service.

Philadelphia

Medical Forum Lectures—The second lecture in the Medical Forum in the auditorium of the Philadelphia County Medical Society will be delivered by Dr Cornelius P. Rhoads of the Rockefeller Institute for Medical Research, New York, March 13, on "The Newer Knowledge of Blood Diseases." Dr Walter C. Alvarez, Rochester, Minn., will give the third lecture, April 24 on "The Emergence of Modern Medicine from Ancient Folkways."

Symposium on Cancer—Nine physicians will present a symposium on cancer before the Philadelphia County Medical Society, March 11. Various aspects of the disease will be discussed by Drs Stanley P. Remann, whose subject will be pathology, George E. Pfahler, x-ray treatment, Frank C. Knowles the skin, George M. Dorrance, the mouth, John Stewart Rodman, the breast, George P. Muller, the chest, Damon B. Pfeiffer, the gastrointestinal tract, Leon Herman, the genito-urinary tract, and Collier F. Martin, the rectum.

RHODE ISLAND

Bills Introduced—S 76 proposes to create a board of examiners in naturopathy and to enact a naturopathic practice act. The bill defines the practice of the "profession" of naturopathy "as non medical and drugless" and as a science "dealing with the diagnosis and treatment of disease through natural therapeutics." It is to "embrace and include physiological, mechanical and dietetic sciences, such as mechanotherapy, electrotherapy, use of diet and herbs including powdered and dehydrated foods and fruits, and other methods as taught in the various recognized schools of naturopathy, excepting, however, surgery and the prescription of compounded drugs." H 714, to amend the chiroprody practice act, proposes (1) to define chiroprody or podiatry as the "diagnosis of foot and leg ailments, the dressing, padding and strapping of the foot, the making of plaster models of the feet and legs and the palliative medical, surgical, manipulative, electrical and mechanical treatment of functional disturbances of the feet and legs as taught and practiced in the schools of chiroprody, recognized by the examining board" and (2) to permit licentiates to practice chiroprody in all its branches pertaining to foot and leg ailments as taught and practiced in the schools or colleges of chiroprody, not including however, the amputation of the foot or the use of any anesthetic other than local.

SOUTH CAROLINA

Bill Introduced—S 1310 to amend the dental practice act, proposes to make it additional grounds for the revocation of a license to practice dentistry for a licentiate to employ "cappers" or "steerers" to obtain business to obtain any fee by fraud or misrepresentation, to betray wilfully a professional secret, to employ directly or indirectly any student or any suspended or unlicensed dentist to perform operations of any kind to use any advertising statements of a character tending to deceive or mislead the public to advertise professional superiority or the performance of professional services in a superior manner to advertise prices for professional services, to advertise by means of large display, glaring light signs, or any sign containing as a part thereof the representation of a tooth, teeth, bridgework or any portion of the human head to employ or use advertising solicitors or free publicity press agents, to advertise any free dental work or dental examination, or to advertise to guarantee any dental service or to perform any dental operation painlessly.

TEXAS

Personal—Dr David T. Bundy Tyler was recently named health officer of Smith County, succeeding the late Dr Benjamin T. Bryant.—Dr Wiley C. Morrow, Greenville, has been appointed to the state board of medical examiners to succeed the late Dr Herman H. Blankmeyer, Aransas Pass.

Medical Assembly in San Antonio—Dr Roy T. Goodwin, San Antonio, was elected president of the Southwest Texas District Medical Society (fifth and sixth districts of the state medical association) at the International Post Graduate Medical Assembly sponsored by the society in San Antonio, January 28-31. Speakers at the meeting included Drs. Hiram Winnett

Orr, Lincoln, Neb., Edward H. Richardson, Baltimore, Nathaniel G. Alcock, Iowa City, Earl R. Kirklin, Rochester, Minn., Abraham Cantorov, Philadelphia, David P. Barr and Alexis F. Hartmann, St. Louis, John R. Hume and Edward William Alton Ochsner, New Orleans, Clement L. Martin, Chicago, Francisco de P. Miranda and Teofilo Ortiz y Ramirez, Mexico City.

UTAH

Annual Registration Due April 1—All practitioners of medicine and surgery licensed to practice in Utah are required to register annually on or before April 1 with the department of registration and to pay a fee of \$3. If a licentiate fails to reregister within from ninety days to six months after April 1, his license can be revoked, and if revoked it will be reinstated only on his paying the delinquent registration fees and an additional year's fee as a penalty.

WASHINGTON

Microscope Stolen—Dr. Willard F. Goff, Seattle, reports that his comparatively new Spencer microscope was stolen from King County Hospital, Seattle, in the few days preceding February 23. The instrument is number 120478, is black with chromium trimmings, and has a black cloth cover and a yellow wooden case with a nickel handle. It has three objectives (including a fluorite oil immersion) and a mechanical stage with graduations. Dr. Goff's name is on the book of directions and on the bottom of the case. The substage mirror is missing and a black metal substage was also taken.

WYOMING

Annual Registration Due April 1—All practitioners of medicine and surgery licensed to practice in Wyoming are required by law to register on or before April 1 with the secretary of the Board of Medical Examiners and to pay a fee of \$2.50. If a licentiate fails to pay the fee within three months after April 1, his license can be annulled and if annulled it will be reinstated only on his paying the stated fee, plus \$5 as a penalty.

GENERAL

Licenses Lost—Drs. Vincent Edward and Grace St. Clair Wagner, San Dimas, Calif., report that on a recent shopping tour their California medical licenses issued to them Aug. 11, 1927, were left on a store counter. Their medical diplomas issued May 11, 1927, by the University of California Medical School also were lost.

Surgical Congress—The seventh annual assembly of the Southeastern Surgical Congress will be held at the Roosevelt Hotel, New Orleans, March 9-11. In addition to clinics and round table discussions, there will be addresses by the following physicians, among others:

Arthur W. Allen and Henry F. Howe, Boston, Calcified Mesenteric Glands: Their Relationship to Abdominal Pain.
Roger Anderson, Seattle, Fractures of the Shaft of the Femur: An Ambulatory Method.
Guy A. Caldwell, Sberveport, Surgical Measures for Prevention of Gas Gangrene.
George W. Crile, Cleveland, Malignant Hypertension.
Roger G. Doughty, Columbia, S. C., Use of the Time Factor in Peritonitis.
Chevalier Jackson, Philadelphia, Tumors of the Trachea with Special Reference to General Surgical Phases.
James S. McLester, Birmingham, Nutritive Failure as a Cause of Vague Ill Health.
Alan C. Woods, Baltimore, Ocular Manifestations of Intracranial Tumor.

"Cancer Research Aid Fund"—A letter describing an "association for the purpose of financially assisting cancer hospitals, cancer clinics and cancer research stations" has recently been sent to numerous hospitals, universities and research organizations. The letter, which bears the signature of one Maxlar Greenfield as "managing director," asks the recipient to file a detailed statement of activities, financial requirements and purposes for which funds are used. On filing this information the institution will become a member of the proposed association, the letter says. A research organization in New York turned one of these letters over to the Better Business Bureau, which after investigation reported that Mr. Greenfield had not been available personally at any time. In telephone conversations he had said that he had no definite plans as yet, that he knew nothing about cancer, that the idea was his own and that he could not give any further information. When asked if he had promoted other things he replied that he had but would give no details. He is not listed in the New York telephone directory but has desk room in the office of an interior decorator at 570 Seventh Avenue according to the report.

Medical Bills in Congress—Bills Introduced H. J. Res. 505, introduced by Representative Whitte, Idaho, proposes that the Civil Service Commission shall not disapprove the application of any person for examination for medical officer in the Indian Service solely on the ground that such application was filed more than twenty years after graduation from a medical school. H. R. 11505, introduced by Representative Disney, Oklahoma, and H. R. 11525, introduced by Representative McGroarty, California, propose to grant retirement pay to disabled emergency officers at the rate paid them on March 19, 1933, if the disability resulted from disease or injury or aggravation of a preexisting disease or injury incurred in service and directly resulting from the performance of duty. H. R. 11452, introduced by Representative Doughton, South Carolina, proposes, among other things, to abolish the Bureau of Narcotics and to create in the Secret Service Division of the Treasury Department a Section of Narcotics. The bill provides for the appointment of a deputy, to be known as the Commissioner of Narcotics, to be in charge of the section. It expressly provides that the following functions shall be continued to be performed by the Commissioner of Narcotics: (1) All functions performed under treaties to which the United States is a party, so far as such functions require communication or cooperation with foreign governments, (2) all functions relating to cooperation with the states and relating to the development of treaties, with regard to the supervision and control of the traffic in narcotic drugs, and (3) the functions of supervising the legitimate traffic in narcotic drugs.

Requests and Donations—The following gifts have recently been announced:

Woodstock Public Hospital, Woodstock, Ill., \$50,000 under the will of the late Mrs. Jeannie Lee Bentley.
Lankenau Hospital, Philadelphia, \$5,000 from the late Mrs. Josephine Eckert, \$3,000 by the will of the late Caroline Lachenmayer.
Lenox Hill Hospital, New York, \$15,000 by the will of Mrs. Anna Thalmann.
Frisbie Memorial Hospital, Rochester, N. H., \$10,000 worth of x-ray equipment, the gift of former Governor and Mrs. Huntley L. Spaulding, Rochester.
Pennsylvania Hospital, Philadelphia, \$54,369, the residuary estate of Mrs. Hattie Grace Copp. The fund is to be used for research in memory of Mrs. Copp and her husband Dr. Owen Copp, who was for several years superintendent and medical director of the Pennsylvania Hospital for the Insane.
Pennsylvania and Protestant Episcopal hospitals, Philadelphia, \$5,000 each by the will of the late Mrs. Anna M. Moorhead.
Hahnemann Medical College and Hospital, Philadelphia, \$750,000 by the will of Mrs. Ada Norton Jamison to endow rooms and beds in memory of her parents, also River Crest Preventorium, Mont. Clare, Pa., \$10,000.
Bryn Mawr Hospital, Bryn Mawr, Pa., \$5,000 by the will of Albert L. Baily, Haverford.
Mount Sinai Hospital, Philadelphia, \$100,000 from the residuary estate of the late Anthony A. Schwartz after the death of the beneficiaries of three trust funds.
Ossining Hospital, Ossining, N. Y., \$2,000 by the will of Mary Goss Young.
Jewish Hospital of Brooklyn, \$5,000 by the will of Simon Frank Rothschild.
Memorial Hospital, New York, \$5,000 by the will of the late Miss Emeline Roach.
House of Rest at Sprain Ridge, Yonkers, N. Y., \$5,000 by the will of Benjamin Welles.
Jefferson Hospital, Philadelphia, \$10,000 under the will of Edward I. Smith, Jr.
University of Cincinnati College of Medicine, \$12,500 added to the David May Fund, \$5,000 anonymously given for the department of surgery, \$450 from Dean Alfred Friedlander for the Friedlander Fund in internal medicine, \$300 for the Eleanor C. U. Alms Fund.
Elyria Memorial Hospital, Elyria, Ohio, \$50,000 given by David L. and Arthur E. Johnson, Cleveland, as a memorial to their parents.

FOREIGN

Deaths in Other Countries

Dr. Charles Jean Henri Nicolle, director of the Pasteur Institute of Tunis, Tunisia, since 1903, died February 28, aged 69. Dr. Nicolle was born in Rouen, France, studied medicine at the University of Paris and worked under the late Emile Roux at the Pasteur Institute. He was made a professor at the Rouen Medical College in 1893 and in 1896 founded the bacteriology laboratory there. In 1928 he received the Nobel prize in medicine for his research on typhus, notably the discovery that the disease is transmitted by lice in clothes. It was as a result of his discovery that delousing was made a part of army operations during the World War. Other research for which Nicolle was noted included work on the use of convalescent serum in treatment of typhoid and measles, on cholera, trachoma, relapsing fever, undulant fever, cattle plague, leishmaniasis, scarlet fever and German measles.

Prof. Ivan Petrovitch Pavlov, famed physiologist, died in Moscow, February 27, of a form of grip, according to Associated Press dispatches. Born Sept. 14, 1849, the son of a village priest in the district of Ryazan, Pavlov was educated at the University of St. Petersburg and the Military Medical

Academy in St Petersburg, now Leningrad. In 1890 he was appointed director of the department of physiology at the Institute of Experimental Medicine in St Petersburg and in 1897 professor at the Military Medical Academy. Under the Soviet rule Pavlov received special favors from the government, many of which he refused to accept, insisting that he would live in the same manner as other scientists. When he was 85 the government gave him a pension of 20,000 rubles a year, and a fund of a million rubles was made available for extensions of his laboratory in Leningrad. Pavlov's best known work was that on conditioned reflexes, which is considered to have opened the way for new schools of physiology and psychology. He was many times honored for his achievements. In 1904 he received the Nobel prize in medicine for his research on the salivary glands. He was a foreign member of the Royal Society of England and an honorary fellow of the Royal College of Physicians. In the summer of 1935 he served as president of the fifteenth International Physiological Congress at its meeting in Moscow. Pavlov visited the United States twice, first in 1923 as the guest of friends in New Haven, Conn., and in 1929 as the guest of the thirteenth International Physiological Congress, which met in Boston.

Government Services

Retirement of Captain Bell

Capt William H. Bell retired from the medical corps of the U. S. Navy, January 1, on his own application, with the rank of rear admiral. Admiral Bell was born in Wisconsin in 1873. He graduated from the University of Pennsylvania Medical Department in 1897 and was appointed an assistant surgeon in the navy in 1898. Advancing through the various grades of the service, Admiral Bell was the first editor of the U. S. Medical Bulletin when it was established in 1907 and has been head of the division of preventive medicine in the bureau of medicine and surgery. From 1932 to 1934 he was in command of the Naval Medical School.

Examination for Appointment to Public Health Service

The U. S. Public Health Service announces an examination to be held April 13 for entrance into the regular corps of the service in the grade of assistant surgeon (medical only). Applicants must not have passed their thirty-second birthday. They must be graduates of a reputable medical college and must have completed at least one year of internship or its equivalent since graduation. Boards will be appointed in various cities so as to cause as little travel as possible, and travel is at the candidate's expense. The examination will consume about a week. Compensation of officers in the grade of assistant surgeon is \$3,158 a year with dependents and \$2,699 without dependents. Persons wishing to take this examination should request the necessary blanks and information from the Surgeon General, U. S. Public Health Service, Washington, D. C.

Course for Reserve Medical and Dental Officers

The fourth annual medical military refresher course for reserve medical and dental officers of the army, navy and national guard will be held at the University of Michigan, Ann Arbor, April 12-25. Reserve officers living in Michigan, Illinois and Wisconsin on application to their respective commanders may obtain orders to attend this inactive duty school and officers in Ohio, Indiana, Kentucky and West Virginia are invited to attend. The morning hours during the two weeks will be occupied in ward walks, observation of surgical operations, clinical conferences and demonstrations in internal medicine, general surgery and oral and dental surgery. Medical officers will be required to elect either internal medicine or surgery as their clinical field of study in medical school and the University Hospital. The dental officers will follow a course arranged by the school of dentistry and the section on oral surgery at the hospital. The afternoon and evening periods will include lectures and demonstrations on clinical subjects pertinent to civilian practice but also of military importance, military information of value to medical and dental officers and other general discussions by members of the faculties of the university and officers in the reserve and regular services of the army and navy. All inquiries should be directed through military channels.

The Treatment of Paralytic Ileus

Mr. Sampson Handley devoted his presidential address before the Section of Surgery of the Royal Society of Medicine to the treatment of paralytic ileus in acute appendicitis, a subject on which he has done original work. He holds that these cases are amenable to timely and energetic treatment, based on a study of the pathology of peritonitis. He pointed out that so-called general peritonitis is rarely universal, even at the time of death. Peritonitis begins in the pelvis even when the septic focus, such as a pinhole duodenal perforation, is high in the abdomen, and still more in infections arising lower down, such as appendicitis. Unless adhesions form, the infective matter drains rapidly into the pelvis. Thus only limited spread occurs round the original focus, but an intense inflammation arises in the rectovesical pouch, to which the septic products are led. The pelvis fills with pus from below upward. Thence the pus gradually rises into the hypogastric region, and hypogastric rigidity appears. When the peritonitic flood reaches the umbilicus, intestinal paralysis kills the patient. An important consequence of this floodlike invasion of the peritoneal cavity is that the stomach, jejunum and transverse colon remain uninfamed and unparalyzed until the patient is moribund. This is the key to successful treatment.

There are thus three clinical stages of so-called general peritonitis: (1) pelvic peritonitis, (2) hypogastric peritonitis and (3) the hopeless "clinical picture" or textbook stage. In pelvic peritonitis, acute rectal and vaginal tenderness, with edematous thickening of the rectovesical fold and uterosacral ligaments, are found on pelvic examination. There is hypogastric distention and tenderness, and perhaps vomiting, but there is no hypogastric rigidity, though there may be iliac rigidity. If the appendix is pelvic it may be felt as a definite swelling. The patient's life depends on recognizing the next stage, that of hypogastric peritonitis, which is characterized by the supervention of hypogastric rigidity and immobility on the previous hypogastric distention. It is assumed that pelvic drainage has already been done at the appendectomy. Above the umbilicus the abdomen is flat or only slightly distended, still soft and only moderately tender. On palpation a resonant rounded swelling almost as definite in its upper outline as the distended bladder and reaching to the umbilical level, can be felt in the hypogastric region. It is formed by distended coils of small intestine. Mr. Handley calls it the "hypogastric football." Soon the supra-umbilical region though remaining soft and returning some movement begins to share in the distention and the stretching of its muscles may be mistaken for genuine rigidity. Vomiting is vigorous and copious and at first is not offensive. Though obstruction is evidently present, small quantities of flatus may be passed. The hypogastric stage is short, lasting perhaps twenty-four hours. In the third or textbook stage of general peritonitis, rigidity is present above as well as below the umbilicus.

Intestinal paralysis may arise in the pelvic stage. Then only the pelvic intestine—a length of pelvic ileum, and later not invariably and sometimes incompletely, a length of pelvic colon—is paralyzed. In 1910 Mr. Handley described this condition as ileus duplex to emphasize the fact of the two obstructions. He showed that successful treatment depended on recognizing this and performing ileocecostomy and cecostomy. Intestinal paralysis may not supervene until the hypogastric stage. The operative problem is then different for longer and less defined tracts of both large and small intestine are involved in the

paralysis When the "hypogastric football" is palpable the time is short, but it may be assumed that paralysis has not involved the stomach, jejunum and transverse colon Here are the materials for constructing a short but complete alimentary canal above the level of the peritonic flood A distended coil of jejunum is anastomosed to the transverse colon, and the secum is opened Reflux occurs from the anastomosis along the transverse and ascending colon to the cecostomy Within twenty-four hours the almost moribund patient with paralytic ileus is transformed, free discharge occurs, and the abdomen becomes soft and flaccid

Mr Handley holds that enterostomy is not a rational operation for cases of combined obstruction of the lower part of the small intestine and of the lower part of the large unless the latter obstruction is likely to pass off spontaneously in a day or two Spontaneous and sufficiently prompt recovery of the large intestine is unlikely in the grave streptococcal infections of appendicitis Enterostomy drains only the small intestine The obstructed large intestine is prevented by the ileocecal valve from emptying into the small intestine In spite of the enterostomy the patient dies from toxic absorption from the distended large intestine Cecostomy is necessary for drainage of the large intestine It has been objected that the ileotransverse colostomy recommended by Mr Handley is a long and difficult operation involving great strain on the vital resources, but that depends on the technic Only two inches of large and 2 inches of small intestine need be exposed or extracted and local anesthesia usually is sufficient Cecostomy is also performed under local anesthesia and a large rubber catheter is tied into the cecum

The King's Last Illness

The country is shocked by the death of the king after a short illness He attained the age of 70 last June and seemed to be in his usual health up to January 15 when he was out and rode on his pony On the 16th he showed signs of mild bronchial catarrh and on the 17th a serious bulletin was issued by his physicians stating that while the catarrh was not severe there had appeared "signs of cardiac weakness which must be regarded with some disquiet" On the 18th the cardiac weakness and embarrassment of the circulation was slightly increased On the 19th it was announced that in spite of a restless night he had maintained his strength On the 20th the bulletin issued at 10 45 a m stated that he had had a more restful night but that there was no substantial change in his condition At 5 30 p m 'diminishing strength' and at 9 25 'the king's life is moving peacefully toward its close' were announced He died at 11 55

It was the cardiac weakness that proved fatal and this was but a culmination of loss of cardiac reserve In 1928 he had a serious illness—streptococcal septicemia with pleurisy, which terminated in empyema, requiring rib resection He slowly recovered It is suggested that this illness which placed a heavy burden on the heart may have had a casual relation to the last illness It is said to be a remarkable achievement that he should have recovered from the septicemia and reigned for seven years through eventful times

Physical Education in the Schools

A circular has been issued by the board of education to local authorities stating that physical education must have regard not only to the requirements of the school child but also to the wants of those leaving school who will be no less in need of healthy exercise and games There should be a daily period of organized physical activity in every school For girls dancing may on occasion be substituted for games or swimming Taking the country as a whole organized provision for the physical education of youth falls far short of the requirements but any imitation of the centralized methods of some continental

countries is considered altogether inappropriate On grounds of general health there is a strong case for helping the unemployed to maintain and develop their physique More gymnasiums are required if the physical education of young people, employed or unemployed, is to be developed as it should be

The main directions in which our system of physical education calls for improvement are summarized as follows 1 A more complete organization of physical education through the appointment in every area of an adequate number of competent full time or part time men and women organizers, who can advise teachers and help to develop the provision of physical activities 2 A larger output of teachers competent to give gymnasium training also an increase in the number of courses for teachers 3 More thorough organization to enable young people no longer attending school to receive physical education

The Fellowship of Medicine for Postgraduate Education

In an editorial the *Postgraduate Medical Journal* gives an interesting retrospect of the work of the Fellowship of Medicine Until the beginning of the century, organized graduate teaching was almost nonexistent in this country Since the early nineties, certain institutions in London, such as the West London Postgraduate College and the Medical Graduates College and Polyclinic, had been doing valuable work, but they could not make available more than a fraction of the rich and varied medical material of the metropolis To remedy this the Postgraduate Medical Association was founded twenty-five years ago, mainly at the instigation of Osler The war brought its activities to a standstill Immediately after the armistice the presence of many colleagues from overseas, on their way home from the front, gave rise to the Fellowship of Medicine to facilitate "intercommunication in all subjects of professional interest" and the promotion 'of mutual hospitality between fellows and with the dominions and overseas and foreign visitors' In 1919 this new organization was united with the Postgraduate Medical Association under the title of their conjoined names But this title was too cumbersome and the first part was dropped, leaving only the title 'Fellowship of Medicine' From small beginnings the Fellowship of Medicine has grown in influence The number of students annually enrolled has risen from 100 in the years 1919-1923 to nearly 700 in 1935, of which nearly two-thirds are from the British Isles and one third from the British empire overseas

The activities of the fellowship are directed by an executive committee, which is constantly receiving suggestions both from students and from teachers and is thus able to make the fullest use of the available facilities for the varying requirements In the first days of the fellowship, interest was limited to the arranging of lectures and visits to the teaching hospitals But in the teaching hospitals, i e., the medical schools, preference must be given to the undergraduates Therefore use was made of the enormous wealth of clinical material in the nonteaching hospitals, by enlisting the help of their physicians and surgeons and coordinating the hours of visits As no other British center has such a profusion of special hospitals, these were turned to account Thus it was possible to arrange special courses of instruction in diseases of the lungs, heart, skin, urology, proctology and diseases of children The increased number of men who desire to take higher qualifications and who require advanced instruction for the examinations next engaged attention For these courses of lectures, lecture-demonstrations, clinical meetings and finally tutorial classes were arranged chiefly during the evenings so that they could be attended by men engaged in practice during the day The increased demand from the general practitioner for instruction and his inability to visit London frequently over a prolonged period led to the institution of short and intensive week end courses Debates

have also been held on topical subjects, such as tonsillectomy, medicine versus surgery in the treatment of peptic ulcer, and maternal mortality

A New Conception of Mumps

Polyneuritis following mumps is rather rare, hardly twenty cases have been reported. Drs Lamache and Dutrey add four carefully investigated observations which they presented before the Societe medicale des hopitaux. The first patient was a policeman, who had a complex neuritic syndrome, first located in the crural nerve and very painful as a consequence of a primitive meningitis, the onset of which appeared five days before the mumps. The neuritis in its first stages went to make up the picture of the paresthetic meralgia of Roth and then extended to the lower limbs. The second case was a neuritis of the polyneuritic type which occurred ten days after the parotitis. One case was a meningoradiculitis, very painful, which occurred three days before the onset of mumps. Another case occurred two days after the mumps in the form of meningo encephalitis with hemiparesis in a child aged 7 years. These cases suggest to the authors the following comment. The first stage of the neurotic complications of parotiditis is as a rule a very painful neuralgia. The motor symptoms come later most often as paresis. Every part of the nervous system may be related and often many parts at a time. The evolution is favorable. Do not those cases tend to confirm the recent conception, initiated by Bezançon and Philibert, that mumps is secondary to the meningo encephalitic symptoms and the swelling of the parotid glands the consequence and not the cause of the ailment?

A Method of Embalming

In the *Revue de pathologie comparee* Dr S. Icard sets forth a simple and inexpensive technique for embalming, without any mutilation of the body. It can be applied to the provisional preservation of bodies for any purpose. The routine method intravascular injections, does not comply with all conditions and can hardly be made by the general practitioner. Dr Icard prefers to use solution of formaldehyde. The technique consists in keeping the corpse in close contact with the solution internally and externally. The formaldehyde is injected in the body cavities and in the principal organs and the corpse is kept in a metallic coffin hermetically sealed the atmosphere of which is saturated with formaldehyde vapor. The formaldehyde is injected directly in large amounts through the abdomen, in the right hypochondrium and the stomach and around the liver, a syringe introduced into the nostrils sends another stream into the esophagus. Then the lungs are injected by way of the thorax and trachea and then the brain, by the ethmoid or the orbits. In all two or three liters must be used for an adult corpse. The coffin must be double lead or zinc for the interior wood for the outside. It must be filled with sawdust, impregnated with 4 or 5 liters of solution of formaldehyde. If necessary one can of course substitute for the lid of the coffin a carefully fitted glass which would permit the body to be viewed for an indefinite period.

Vaccination in France in 1934

As usual, a report was made to the Academie de medecine as to vaccination in the calendar year 1934. The results are fairly satisfactory, although in some instances the local authorities lacked means to enforce the law. Vaccination is compulsory at birth in the tenth year and at 21 but women escape, generally speaking this last obligation. In continental France including Corsica the total number of vaccinations and revaccinations was 1,394,446 in a population of 41,696,771 persons.

The law includes penal provisions against refractory persons, but the mayors, who are in charge of enforcement, too often forgot it and do not deal severely. In one department only (Seine inferieure), more than 1,370 policemen's reports were drawn up, and the great majority of law-breakers were dealt with leniently. Only thirty one were held culpable. The complications comprised only some general reactions after vaccination, some local reactions, including two adenitis, and two deaths.

The New Law Extends Professional Secrecy

Professional secrecy has been regarded at all times as one of the most important of a physician's obligations. It stands to reason that this fundamental proposition should find a place in the revised basic law of the medical profession. Heretofore it has been dealt with in the penal code, where it has been applied to solicitors, apothecaries and others as well as to physicians, and it has further been established by a number of criminal and professional decisions. In the recently promulgated German reichsärzteordnung (reich physicians' ordinance) professional secrecy is removed from the general body of criminal law and formulated anew. According to the penal code, physicians and their assistants have been liable to a fine or to imprisonment for a period not to exceed three months on conviction of having divulged, without authorization, confidential secrets entrusted to them in virtue of their office, profession or trade. Now, according to the reichsärzteordnung, a physician incurs the penalty of a fine or of imprisonment not to exceed one year or both, whenever he "reveals, without authorization, another person's secret entrusted or made known to him in the course of the practice of his profession." The definition has thus been extended. Heretofore the physician has been placed on a level with his assistants and others connected in some capacity with his professional activities. Medical students too were drawn into the question of medical professional secrets. Likewise a person was punished who, after the death of a physician, made known a secret that had been obtained through the laxity of the physician. Such secrets could be revealed only with the consent of the patient involved.

But the new ärzteordnung does not confine itself to the restatement of an old provision of the penal code, rather for the first time, it formulates rules to govern the exceptional cases in which a violation of professional secrecy would be permissible. "The physician is not subject to penalty, if he reveals such secret in the course of fulfilling a lawful or moral duty, or if such revelation of the secret serves a sound, legitimate public spirited purpose and when continued secrecy would do more harm than good." The principle is not fundamentally new that in cases in which professional secrecy serves to protect a criminal offense a physician is released from his obligation. While heretofore the law has been obscure on the matter of secret violation as a matter of actual legal practice the conflicting duties of the physician and his right to violate professional confidences in certain cases have been equitably taken into account. For example. A physician treated a woman who had a contagious disease. This woman showed affection for the children of a neighbor. The physician deemed it necessary to warn this neighbor. Brought to trial for violation of professional secrecy he was tactfully acquitted although contestable arguments were made in his behalf. This was more than thirty years ago. In another case, recently reported, a woman patient, while in a narcosis revealed to a physician an old crime committed by her husband. For this crime an innocent man was serving time. It was indisputable that in such circumstances the physician could not simply keep silence. Now this sort of

thing receives sanction in the basic law. But the innovation goes further still, the obligation of secrecy is no longer the self-evident starting point of the problem. It ceases to be so the moment the law provides that secrecy may be annulled by circumstances involving a "legitimate public spirited purpose," even where no moral duty is involved. For, as between the maintenance of secrecy and a consideration of public welfare the latter henceforth preponderates. Heretofore, because of a lack of legal precedents, little light has been shed on the latter subject. It may be possible, for example, for a physician to obtain, under seal of secrecy, knowledge of some unsolved crime. It is to be taken for granted that problems of this sort may, even under the new law, still be difficult of solution. Important as is the threatened equity, the inequity of a violation of secrecy may be equally serious, even more so. For in professional secrecy is rooted that confidence of the patient without which the physician cannot function.

The Condition of the Sick Insurance Societies

The latest figures on the condition of the sick insurance societies have just been made public. The average number of members of the state-regulated sick insurance societies (not including the so called ersatzkassen [indemnification societies] which are of no substantial importance) amounted in the period from October 1934 to September 1935 to 18,500,000, namely, 1,700,000 (10.2 per cent) more than in 1933. The greatest relative increase was noted in industrial and trade guild sick insurance societies (23.6 and 18.7 per cent, respectively). The membership in the municipal insurance societies had increased around 8 per cent, that of the mine workers' sick insurance societies around 4.9 per cent and that of the rural sick insurance societies around 3.8 per cent. The number of persons incapacitated by illness stood at 7,300,000 from October 1934 to September 1935, against 6,100,000 in 1933, that is to say about 20.7 per cent greater. For each 100 members there were, for the same periods compared, forty persons incapacitated by illness (1934 to 1935) against thirty-six (1933). This increase can probably be almost entirely attributed to the improvement in industry, the more the work is speeded up, the greater the demands on the body, this is particularly true when a certain number of newly employed workers are not accustomed to the exertion required.

Total expenditures of these insurance societies amounted from October 1934 to September 1935 to 1,245,400 reichsmarks, the intake for the same period grossed 1,181,400. The intake was up 14.6 per cent and the amount paid out 21.1 per cent as compared with the calendar year 1933. Instead of a surplus in excess of 2,700,000 reichsmarks a deficit of 64,000,000 is shown, which, however, stands against unencumbered assets of 800,000,000. The expenditure calculated per member increased from 61.12 to 67.15 reichsmarks, or about 9.9 per cent. In terms of the particular types of sick care provided by the insurance societies (for members and their families) the disbursement increased as follows: medical treatment around 2.2 per cent, hospital care around 2.3 per cent, dental service 10.9 per cent, medicines and other therapeutic supplies 20.1 per cent. Any critical examination of these increases must take into consideration, however, that from 1929 to 1933 by far the smallest change took place in the cost of hospital care and by far the greatest in the cost of dental care. The amount expended on dental care was in 1933 around 7.6 per cent and from October 1934 to September 1935 around 19.14 per cent above that of 1929. The rate of increased expenditure for medicaments and hospital care for the dependents of members is greater than that for the members themselves: 3.2 per cent against 4.2 per cent. Of the remaining services, care in childbirth showed the greatest increase (around 35.8 per cent) owing to the increase in the number of births, but the payment of death claims has also considerably increased (around 17.6 per cent).

Intoxication in Traffic Accident Statistics

Greater attention is constantly being given to the part played by intoxication as a cause of accidents. Accident statistics for Bavaria covering the years 1930 to 1934 inclusive are available. The only differentiation made in this enumeration is between pedestrians and drivers of vehicles. According to official police records, intoxication as a cause of accidents was established in the number of cases given in table 1.

TABLE 1—*Intoxication as a Cause of Accidents*

	Drivers	Pedestrians	Total
1930	646	170	816
1931	525	125	650
1932	495	106	601
1933	436	67	503
1934	780	113	893

Up to 1933 the number of intoxicated showed decided substantial decreases from one year to the next. Even in 1933, although an increase in cases of intoxication was feared on account of the greater volume of motor traffic, the decline continued further. Noteworthy therefore is the rise in 1934 in the number of drunken drivers (increase of 79 per cent) as well as in the number of pedestrians (increase of 68.7 per cent).

No less important is the ratio between the number of accidents due to drunkenness and the total number of accidents for

TABLE 2—*Relation of Accidents Due to Drunkenness to the Total Number*

	Driver Responsible All Causes	Per Cent Intoxicated	Pedestrians Responsible All Causes	Per Cent Intoxicated	Total Responsible for Accidents	Per Cent Intoxicated
1930	16,158	3.98	2,157	7.67	18,315	4.44
1931	14,037	3.73	1,775	6.93	15,812	4.1
1932	12,573	3.93	1,620	6.48	14,193	4.93
1933	11,676	3.72	707	8.48	12,383	4.6

which both drivers and pedestrians are responsible. As the number of drunken women involved is negligible, the figures in table 2, for the four years including 1933, represent only male offenders.

According to the figures, the number of guilty drivers and pedestrians decreased up through 1933, yet the relative proportion of intoxicated persons showed marked fluctuations and was higher for pedestrians than for drivers.

The Brussels Medical Convention

Endocrinology was the subject discussed this year by the Brussels Medical Convention (Journées médicales de Bruxelles). The role of the glands of internal secretion in the pathogenesis of arterial hypertension was discussed by Mr. Maurice Roch, professor of the Geneva Faculty of Medicine. He stated that those glands the secretions of which are increased under the influence of an orthosympathetic excitation provoke hypertension while glands that obey the parasympathetic exert a hypotensive influence. The internal secretions of the pancreas, antagonists of epinephrine, have a hypotensive effect. Insulin, interesting in this connection from a theoretical point of view, is hardly to be employed in practice. Testicular insufficiency would not of itself seem to cause hypertension. The same appears true of ovarian insufficiency. Thyroid hyperfunctioning produces a certain degree of hypertension. As for the suprarenals their prominent role in producing crises of paroxysmal hypertension is well known. The hypophysis is interesting in several respects. (1) the posterior lobe that furnishes sub

stances acting on the smooth fibers is energetically hypertensive, (2) the adenoma of basophil cells in the anterior lobe, described by Cushing, produces a specific type of hypertension (3) certain products secreted by the anterior lobe and which act on the thyroid, suprarenals and gonads may be the indirect cause of hypertensive crises. Little is known of the effects produced by the parathyroids, the liver and the kidneys, on the other hand, certain decomposition products of metabolism, such as choline and adenylic acid, are vasodilators and hypertensors. The production of these substances may perhaps explain the good reaction to muscular exercises observed in many persons with hypertension whose hearts are yet resistant.

Postencephalitic obesity was studied by Mr. René Cruchet, a professor at Bordeaux. One, two or even more years after the acute stages of epidemic encephalomyelitis, obesity frequently develops. This may be regarded as a sequela of the disease and, although stubborn, it usually moderates. Such forms of obesity may be reasonably related to certain states of emaciation following attacks of epidemic encephalitis. Both conditions are evidently due to hypophyseal disturbances.

Mr. N. Goormaghtigh, professor on the Ghent Faculty of Medicine, discussed the autonomic nervous system. In a histologic study he seeks to determine the importance of parasympathetic tissue. His paramount objective is to clarify an idea that is still a subject of controversy: the conveyance of humors to the synapses and nerve terminations of the sympathetic nervous system. It might be asked: Is not the liberation of sympathicotrophic substances registered on the ganglions, the seat of the synapses, conditioned by a stimulation of attached parasympathetic ganglions? It is interesting to note the integrity of the parasympathetic ganglions and the maintenance of their histochemical character after sympathectomy and double adrenalectomy. The author calls attention to the existence in mice of parasympathetic ganglions connected with the branches of the vagus that lead to the stomach and to the celiac plexus. These parasympathetic ganglions are characterized by a more compact grouping of cells and by the absence of chromaffin. The sympathetic nervous system possesses centripetal fibers as well. There are two known vasosensory reflexogenic zones, the sinus caroticus and the arch of the aorta. These zones have a vascular connection with the glomus caroticum and the glomus of Pletschka, the latter of which is situated between the pulmonary artery and the arch of the aorta. Other zones recording the variations of local circulation are found distributed throughout the vascular system, such as Ruffini's corpuscles of the skin (Masson), the glomus coccygeum of Luschka, the neuromuscular juxtaglomerular apparatus of the kidney and the coats of Weidenreich in the spleen.

Mr. L. Mayer, agrégé of the University of Brussels, who discussed clinical results from the use of ovarian grafts based on his remarks on eighty-eight bilateral ovariectomies with ovarian grafts. He states emphatically that the operation should be supplemented by autograft of healthy ovarian fragments. If the uterus also must be removed, it is preferable to limit the hysterectomy to the supra-isthmus portion and thus permit menstruation in at least some of the cases.

Mr. F. de Quervain, professor of clinical surgery at the Berne Medical Faculty, discussed surgery in malignant goiter, pointing out that the majority of malignant goiters develop in a benign goiter that has persisted. The author distinguishes between two types both marked by a slow growth and attenuated malignancy—the proliferating adenoma and the papillary. A third intermediary type, the hemangioendothelioma, is more malignant than the first two. Finally, there is epithelioma and sarcoma. Whenever a benign goiter increases in size especially from the fifth decade on without apparent reason that is to say, not following pregnancy or intracystic hemorrhage, malignancy should be suspected. The treatment comprises radical operation followed by irradiation with radium or

x-rays. The results are survival of one third of the patients after three and even five years. The results obtained in the treatment of cancer proper and sarcomas continue to be misleading.

Mr. A. P. Dustin, professor at the Brussels Faculty of Medicine, defends the idea of the thymus as essentially a focus of nucleoprotein accumulations. The cells containing such accumulations are of an extreme lability, and they are therefore easily liberated, probably along with certain humoral substances, by the thymus. While absence of the thymus is extremely rare, a reduction in the volume of the gland may result from infection, alimentary insufficiency, fever, suppuration or prolonged fasting. In simple hypertrophy the subjects show retarded growth, signs of mild rachitis, dyspnea, chronic bronchitis, lack of vasomotor equilibrium and frequently glottic spasm, sometimes with serious and even fatal accidents. In thymic lymphatic hypertrophy the child appears bloated, obese, rachitic, and subject to mucocutaneous disorders (dermatoses, blepharitis, rhinitis, enterocolitis and so on). Thymic enlargement takes place during the course of exophthalmic goiter. Although the pathogenesis of thymic hypertrophy is not well understood, it is known that the volume of the organ may be increased by a diet rich in nucleoproteins.

Rechlorination After Prostatectomy

Dr. Van Den Branden reported to the Belgian Urologic Society the remarkable results of his method of immediate rechlorination after prostatectomy by injection of a 20 per cent hypertonic solution of sodium chloride. The results may be summarized as follows: diuresis considerably increased, absence of postoperative shock, scarcely any postoperative azotemic pressure. The procedure will make anuria a rarity. This harmless prophylactic measure is therefore most emphatically indicated.

The Bunge Research Center

Thanks to the generosity of a wealthy citizen, Antwerp has possessed for the past year a center of medical and biologic research, the Bunge Institute (l'Institut Bunge). There is a diagnostic section and an experimental section where the most elaborate research can be pursued. It is under the direction of Mr. Van der Stricht, who first conceived its organization. Among his colleagues should be mentioned Prof. Ludo Van Bogaert in the field of pathologic anatomy and his brother in the field of physiology. The institute organizes lectures to which the physicians of Antwerp and vicinity are invited. In one of these lectures Mr. Negre of the Pasteur Institute some months ago outlined his researches on tuberculosis. December 15, Prof. Georges Mouriquand of Lyons described his work in a lecture on "Clinical Avitaminoses."

Marriages

JAMES BROWN SHELTON to Miss Elizabeth Caroline McReynolds both of Birmingham Ala. Dec. 14, 1935.

MARVIN I. McCLAIN, Scottsburg, Ind., to Miss Harriett Ford in Kankakee, Ill., Dec. 21, 1935.

HARRISON JOHNSTON SHULL to Miss Margaret Cavert both of Nashville, Tenn., Dec. 28, 1935.

DEWITT HENDREE SMITH to Miss Mary Campbell Smith both of New York in December 1935.

THOMAS GREGORY DOLGHERTY to Miss Kathleen M. Brock both of New York February 22.

FURMAN YATES SORRELL to Miss Julia L. Little both of Wadesboro, N. C. Dec. 3, 1935.

RUSSELL T. DRAPER, Cambridge, Mass., to Miss Edith E. Tucker of Dedham recently.

CLARENCE W. ROGERS, Rineville, Ky., to Mrs. Malinda Raine of Vine Grove, January 16.

FLOYD W. SHAFER, Gilbert, Pa., to Miss Lucy J. Erwin of Bethlehem February 19.

Deaths

William Bradbury McClure * Evanston, Ill., Johns Hopkins University School of Medicine, Baltimore, 1912, house officer, Harriet Lane Home for Invalid Children, Johns Hopkins Hospital 1912-1913, assistant resident and resident physician Children's Memorial Hospital, Chicago, 1913-1915, instructor in pediatrics, State University of Iowa College of Medicine Iowa City, 1915-1916, associate in pediatrics, Northwestern University Medical School, since 1930, attending pediatrician, Evanston Hospital, since 1918 and associate physician since 1930, attending physician to the Children's Memorial Hospital, Chicago, since 1920, fellow, at one time director, associate member, and member of the Otho S. A. Sprague Memorial Institute Laboratory for Research of the Children's Memorial Hospital served during the World War, member of the American Pediatric Society and the American Academy of Pediatrics contributed to pediatric textbooks and to the periodical literature, aged 51, died, February 13, of hypertensive cardiovascular disease and acute angina pectoris

George Gellhorn * St. Louis, Julius-Maximilians-Universität Medizinische Fakultät Würzburg, Bavaria, Germany, 1894, since 1932 professor of clinical obstetrics and gynecology Washington University School of Medicine, professor and director of the department of gynecology and obstetrics, St. Louis University School of Medicine, member and past president of the American Gynecological Society, fellow of the American College of Surgeons, member of the Deutsche Gesellschaft für Gynaekologie, aged 65, on the staffs of the Barnard Free Skin and Cancer Hospital, City Hospital Missouri Pacific Hospital, St. Louis Maternity Hospital Barnes Hospital, Jewish Hospital and St. Luke's Hospital, where he died, January 25, of heart disease

William Lawrence Clark * Philadelphia, University of Pennsylvania Department of Medicine, Philadelphia, 1903, past president of the American Academy of Physical Therapy, American Physical Therapy Association and the American Congress of Physical Therapy, member of the American College of Radiology and the American Radium Society, formerly lecturer on electrotherapeutics, Jefferson Medical College, at various times on the staffs of the Jefferson, St. Agnes' and St. Mary's hospitals, formerly owner of a hospital bearing his name, author of numerous articles in literature, and contributor of chapters to "Keen's Surgery," "Da Costa's Surgery" and "Mock's Practice of Physical Medicine", aged 59, died, January 12, of biliary infection

James Fairchild Baldwin * Columbus, Ohio, Jefferson Medical College of Philadelphia, 1874, professor of physiology and anatomy, Columbus Medical College, 1875-1882, professor of surgical gynecology and chancellor, Ohio Medical University, 1892-1899, and formerly professor of clinical surgery, Ohio State University College of Medicine, member and past president of the American Association of Obstetricians, Gynecologists and Abdominal Surgeons, past president of the Ohio State Medical Association, surgeon and chief of staff, Grant Hospital, author of "Operative Gynecology," 1898, aged 85, died, January 20, of carcinoma of the stomach

William Johnson Taylor * Philadelphia University of Pennsylvania Department of Medicine, Philadelphia, 1882, member of the American Surgical Association past president of the College of Physicians of Philadelphia and the Philadelphia Academy of Surgery, served during the World War at one time professor of orthopedic surgery, Philadelphia Polyclinic, for many years attending surgeon to the Philadelphia Orthopedic Hospital and Infirmary for Nervous Diseases on the staffs of St. Mary's, St. Agnes', Philadelphia General and the Woman's hospitals, aged 74, died, January 22, of bronchopneumonia

Isaac Scott Stone, Washington D. C., University of Maryland School of Medicine, Baltimore, 1872, member of the Medical Society of the District of Columbia a founder, vice president in 1905 and president in 1918 of the Southern Surgical Association for many years professor of gynecology and abdominal surgery, Georgetown University School of Medicine, fellow of the American College of Surgeons on the staff of the Columbia Hospital for Women, aged 84, died Dec. 22, 1935 of cerebral thrombosis

Jeffrey Charles Michael * Houston, Texas Tulane University of Louisiana Medical Department, New Orleans, 1909, chairman of the Section on Dermatology and Syphilology, American Medical Association, 1934-1935, member of the American Dermatological Association, formerly secretary of the Harris County Medical Society, served during the World War,

on the staffs of the Jefferson Davis and Hermann hospitals aged 47, died, January 21, as the result of a fall from a tenth story window

Justus Ohage, St. Paul, University of Missouri School of Medicine, Columbia, 1880, member and past president of the Minnesota State Medical Association, past president of the Ramsey County Medical Society, at one time professor of clinical surgery, University of Minnesota Medical School, Minneapolis, Civil War veteran health officer of St. Paul, 1899-1918, aged 86, died, Dec. 26, 1935

Louis Fleming Fallon * Augusta, Maine, University of Pennsylvania School of Medicine, Philadelphia, 1916, fellow of the American College of Surgeons, on the staffs of the Veterans Administration Facility, Gardiner (Me.) General Hospital, Sisters Hospital, Waterville and the Augusta General Hospital, aged 44, died, January 8, of cerebral hemorrhage

Thomas M. Blake, Double Springs, Ala., University of Nashville (Tenn.) Medical Department, 1907, member of the Medical Association of the State of Alabama, past president of the Winston County Medical Society, formerly superintendent of education of Winston County, aged 63, died, Dec. 29, 1935 in a hospital at Jasper

Edgar Klopp Conrad * Hackensack, N. J., Bellevue Hospital Medical College, New York, 1893, past president of the Bergen County Medical Society, on the staff of the Hackensack Hospital, aged 65, died, January 27, of carcinoma of the head of the pancreas with metastasis to the liver

Jane Ketchum Wildrick Banes, Damascus, Pa., Woman's Medical College of Pennsylvania, Philadelphia, 1909, member of the Medical Society of the State of Pennsylvania on the staff of the Carbondale (Pa.) General Hospital, aged 59, died January 5, of cardiovascular renal disease

Erestus Talbot Hanley, Seattle, Rush Medical College, Chicago, 1905, member of the Washington State Medical Association, past president of the Western Branch of the American Public Health Association, aged 59, on the staff of the Providence Hospital, where he died, January 23

Robert William Benner * Tiffin, Ohio, University of Michigan Medical School, Ann Arbor, 1925, vice president and formerly secretary of the Seneca County Medical Society, on the staff of the Mercy Hospital, aged 37, died, January 4, of pneumonia following scarlet fever

Earl Albert Linger * Oconto, Wis., Rush Medical College, Chicago, 1914, served during the World War, health officer of Oconto, on the staff of the Oconto City and County Hospital, aged 48, died, Dec. 22, 1935, in St. Vincent's Hospital, Green Bay, of pneumonia

Marion Cicero McClain, Tate, Ga., University of Georgia Medical Department, Augusta 1887, member of the Medical Association of Georgia aged 76, died, Dec. 25, 1935, of anuria in chronic nephritis and edema of the lungs

Delzie Roy Lee * Indianapolis, University of Louisville (Ky.) Medical Department, 1916, served during the World War, on the staffs of St. Vincent's and Methodist hospitals, aged 45, died suddenly, January 3, of coronary occlusion

Louis Lorenzo Kelley, Okemos, Mich., University of Michigan Department of Medicine and Surgery, Ann Arbor 1875, formerly state senator, aged 86, died, Dec. 21, 1935, of hypostatic pneumonia

Willard Rea Allison, Lafferty, Ohio, Western Pennsylvania Medical College, Pittsburgh, 1901, member of the Ohio State Medical Association, aged 62, died, January 9, of cerebral hemorrhage

Max Charles Hawley * Agnew, Calif., Central College of Physicians and Surgeons, Indianapolis, 1904, on the staff of the Agnews State Hospital, aged 56, died, Dec. 28, 1935, of coronary thrombosis

James Elias Dodson, South Pasadena, Calif., University of Nashville Medical Department 1885, aged 78, died, Dec. 16, 1935 in the Pasadena Hospital, of a hip fracture and pneumonia

Szymon Szudrawski, Manistee, Mich., University of Michigan Department of Medicine and Surgery, Ann Arbor, 1899, aged 69, died Dec. 23, 1935, of carcinoma of the stomach

Jerre C. McMahan, Los Angeles Vanderbilt University School of Medicine, Nashville, Tenn. 1881, aged 85, died, Dec. 29, 1935, of cerebral hemorrhage and bronchopneumonia

John Matson Stowell, San Francisco, College of Physicians and Surgeons of San Francisco, 1901, aged 73, died, Dec. 18, 1935 of hypertension, myocarditis, uremia and nephritis

Oliver Perry Pisor, Monmouth, Calif., Jefferson Medical College of Philadelphia, 1881, aged 82, died, Dec. 20, 1935, of coronary occlusion and arteriosclerosis

VITAMIN D AND PARATHYROID HYPERPLASIA

To the Editor—In a recent article (THE JOURNAL, February 8, p 427) Wilder and Howell discussed the relationship of vitamin D to parathyroid hyperplasia and concluded that the latter was compensatory. Quick and Hunsberger (THE JOURNAL, March 7, 1931, p 745), who in their study of hyperparathyroidism likewise considered the relation of vitamin D to parathyroid hyperplasia, reached similar conclusions and presented as a possible explanation the hypothesis that the maintenance of the calcium level in the blood is under the dual control of vitamin D and the parathyroids, the former aiding in the absorption of calcium from the intestinal tract, the latter in mobilizing the element from osseous tissue, and that when a depletion in the supply of vitamin D occurs the entire burden of maintaining the normal concentration of serum calcium is thrown on the parathyroids. Under those conditions the organism responds by means of a physiologic hyperplasia of these glands. Quick and Hunsberger furthermore emphasized the value of administering large doses of vitamin D preoperatively to guard against postoperative tetany, a serious and frequent complication following the removal of a parathyroid adenoma. It appears that this suggestion has received relatively little attention. Nevertheless, the fact that it is based on sound experimental evidence, is exceedingly simple and entirely without harmful effect warrants that attention be again directed to it.

ARMAND J. QUICK, M.D., Milwaukee

SPLANCHNIC NERVE SECTION IN JUVENILE DIABETES

To the Editor—In THE JOURNAL, January 25, page 279, Dr J. M. Rogoff reported the production of Addison's disease following adrenal denervation in a patient with diabetes. He pointed out the real danger of interfering with the blood supply of the cortex and also emphasized the fact that the sectioned nerves regenerate in a few weeks. This report, together with the editorial comment on it, no doubt will deeply impress the medical profession with the hazards of adrenal denervation.

The surgical procedure of adrenal denervation is frequently confused with splanchnic nerve section, an operation that is performed without any hazard to the blood supply of the cortex.

In several publications (*Arch Surg* 26:750 [May] 1933, 30:151 [Jan] 1935; *Ann Int Med* 7:422 [Oct] 1933, 7:1201 [April] 1934; *Ann Surg* 102:22 [July] 1935) my co-workers and I on the basis of experimental evidence and clinical observations stated that (1) splanchnic nerve section produces an identical change in carbohydrate metabolism with adrenal denervation, (2) the additional denervation of pancreas and liver may be an added advantage, (3) interference with the blood supply of the adrenal does not take place after splanchnic nerve section nor has a single clinical case or considerable experimental material shown any cortical insufficiency, (4) regeneration of the nerve fibers can be effectively prevented in the supradiaphragmatic approach by anastomosing the proximal end of the splanchnic nerve to an intercostal nerve.

Both objections to adrenal denervation then, namely, interference with adrenal blood supply and early regeneration, can be met by splanchnic nerve section. Should one feel that this is not a complete denervation of the adrenal, the upper two lumbar sympathetic ganglia can be sectioned.

The third and most important criticism of this article is leveled against tampering with the adrenals in case of many unrelated conditions. Again one can most heartily agree with this view. In the case of severe, juvenile, insulin resistant

diabetes, however, my co-workers and I have accumulated sufficient data to justify splanchnic nerve section in carefully selected cases. This operation is done with the view of collecting data over a long period of time on patients whose disease hazard is not as small as some might believe. The low mortality statistics of Joslin, Wilder and Allen, and Priscilla White cannot be reproduced in the country at large. The actuarial statistics of the Metropolitan Life Insurance Company portray a sad picture of diabetes mortality. In an average of four individual statistics of diabetic mortality in different states of the United States and Canada, roughly one third of all patients who died of diabetes had never used any insulin and less than half of them ever tested their urine (*J Kansas M Soc* 36:177 [May] 1935). Thus in addition to other considerations a definite social and economic indication must be recognized in the selection of diabetic children for operation.

The object of this operation on juvenile diabetic patients is to slow down or inhibit excessive glycogenolysis. Not the adrenal gland but the liver is the center of the attack. Splanchnic nerve section produces increased glycogen storage and fixation and this is all we wish to accomplish with the operation.

We are continuing our experiments on the surgical treatment of juvenile diabetes. So far the postulate of the editorial that the therapeutic hazard should not exceed the disease hazard has not been overstepped.

GEZA DE TARATS, M.D., Chicago

THE PRACTICAL FACTOR IN DRUG NIHILISM

To the Editor—Dr Norman A. David in his article "The Recent Graduate and Drug Nihilism" (THE JOURNAL, February 1, p 405), accuses the recent graduates of drug nihilism. The real cause, which he failed to mention, is the modern drug store with its glorified counter prescribers, especially in a small town where a druggist treats everything from cancer to venereal diseases. The doctors in these small communities are forced to dispense their own drugs, hence they deal with houses whose medicines are reliable and their composition known. Let us reform these unlicensed practitioners! Let us have more rigid laws! Why should we fatten the pocket books of the druggists with our prescriptions? If the evil is destroyed then our young doctors, especially in the towns, will go back to the art of pharmacology and posology.

F. F. SCHWARTZ, M.D., Fairport Harbor, Ohio

HEART BLOCK AND PREGNANCY

To the Editor—In THE JOURNAL, February 15, page 532, in an article on heart block and pregnancy, by Mitchell Bernstein, the following statement is made: "It is interesting to note that a study of the literature up to Jan 1, 1936, yielded only six recorded cases of complete heart block in which successful gestation had occurred." The six cases listed by the author were reported by Jeanmn and Clerc, Clerc and Levy, Laubry, Titus and Stevens, Dressler and Herrmann and King.

For the sake of completeness may I add that three years ago I reported a case of complete heart block that was found in a pregnant woman (*Am J Obst & Gynec* 25:125 [Jan] 1933). As was done in Bernstein's case, I performed a cesarean section under local anesthesia and delivered a living child. The mother's recovery was uneventful. In my article I mentioned eleven previously reported cases of complete heart block associated with pregnancy. The first case of this kind was reported by Freund (*Ztschr f Geburtsh u Gynak* 30:175, 1918). This patient an octipara, died after having had a miscarriage. She also had had signs and symptoms of heart block during her seventh pregnancy. The second case was

reported by Walz (*Zentralbl f Gynak* 46 1941, 1922) In this case pregnancy was uneventful and labor was easy and spontaneous One of the two patients with complete heart block observed by McIlroy and Rendel (*J Obst & Gynaec Brit Emp* 38 7, 1931) went through two gestations, the second of which terminated in the delivery of twins In the series of eleven cases of complete heart block complicating pregnancy that were reported in my article, there were two deaths (Freund and Herskovics)

FELTON'S SERUM AND DIATHERMY IN PNEUMONIA

To the Editor—1 Why isn't Felton's serum more generally used by the profession in the treatment of pneumonia? 2 Please give reference to the latest contribution on this subject 3 Is it conceded that diathermy produces sequela such as empyema if used in the treatment of pneumonia? 4 Do you approve, when indicated of the use of diathermy in pneumonia? Please do not sign name

M D New Jersey

ANSWER—1 Physicians who have the largest experience in the management of the pneumonias regularly use refined and concentrated serums in the treatment of those pneumonias for which serums are available This statement is based on published reports from Bellevue Hospital (Cecil, R L, and Plummer, Norman Pneumococcus Type I Pneumonia, *THE JOURNAL*, Nov 22, 1930, p 1547) and Harlem Hospital (Bullock, J G M Studies in the Serum Treatment of Pneumonia, *New York State J Med* 33 13 [Jan 1] 1933) of New York and from Massachusetts (Sutcliffe, W D and Finland, Maxwell Type I Pneumococcus Infections, with Special Reference to Specific Serum Treatment, *New England J Med* 210 237 [Feb 1] 1934, Heffron, Roderick, and Anderson, G W Two Years' Study of Lobar Pneumonia in Massachusetts *THE JOURNAL*, Oct 21, 1933, p 1286) and Great Britain (Report of the Therapeutic Trials Committee of the Medical Research Council The Serum Treatment of Lobar Pneumonia, *Lancet* 1 290 [Feb 10] 1934) Physicians with less experience and opportunity for observation of the pneumonias are more frequently using serum in the treatment of pneumonia whenever they have been educated to do so by such intensive campaigns as have been undertaken in Massachusetts and New York

Physicians may refrain from the use of Felton's serum because of ignorance of its benefits, fear of untoward serum reactions, or mistaken motives of economy Modern methods for differentiating and studying the pneumonias have changed the point of view concerning their treatment Stress is now placed on specific treatment and prevention and cure of bacteremia which is present in most fatal cases Serum treatment requires knowledge and skill comparable to those necessary for surgical procedures The prompt dramatic termination of the disease is a gratifying reward for effort Physicians with little experience are prone to expect that their particular patient will not have a blood invasion and will recover without serum by crisis on the eighth day The ordinary death rate in adults from type I pneumonias ranges from 20 to 40 per cent The death rate from pneumonia in children between the second and twelfth year is much smaller than in infants and adults In a large hospital 120 consecutive adult type I pneumonias were treated with serum, with ten deaths, 8.3 per cent No patients succumbed who had been treated before the sixth day

Immediate serum reactions are infrequent and with some lots they do not occur Serum sickness of varying severity occurred in 13 per cent of 500 cases of type I pneumonia Ophthalmic and skin tests for sensitivity should be made before giving serum

To a certain extent the amount of serum required depends on the earliness of administration The cost for serum is frequently no more than the expense for operating room and dressings for patients suffering from appendicitis Against the cost of the serum should be offset the reduced cost of nursing and of oxygen therapy the shorter convalescence the more rapid return to work and the less frequent occurrence of complications The value of the lives saved may be estimated from the tables in Dublin's 'The Money Value of a Man' (Ronald

Press Company, 1930) Massachusetts, Connecticut, Maine and New York supply serum for type I, as do the cities of New York and Detroit All except New York State supply serum also for type II cases Detroit supplies serum for type VII and New York supplies serum for type VII and a number of other types Bullock and Mayer (Hazards of the Induction of Pneumothorax, *THE JOURNAL*, July 20, 1935, p 191) encountered no cases of empyema in fifty-three type I cases treated with serum within the first two days

2 An excellent paper presenting the advantages of the treatment of pneumonia with serum was contributed by William P Belk (The Specific Treatment of Lobar Pneumonia, *THE JOURNAL*, Sept 14, 1935, p 868)

3 It is improbable that empyema can be attributed to the use of diathermy Empyema in pneumonia is the result of a very severe pleuritic invasion and frequently is associated with bacteremia

4 John S Coulter, in a recent review on medical diathermy (*THE JOURNAL*, January 18, p 209), says "In the management of pneumonia, medical diathermy does seem to be of definite benefit in reducing the severity of the thoracic pain It is not an accepted specific treatment in lobar pneumonia"

While oxygen is being administered diathermy should not be employed, because ignition of the bedclothes may occur from small sparks in the presence of oxygen-enriched air In the management of pneumonia it is important to relieve anoxemia

SYPHILIS IN PREGNANCY

To the Editor—A woman aged 27 developed a sore on her lower lip in July 1929 while engaged to a supposedly healthy young man This sore was treated unsuccessfully for some weeks until finally a Wassermann test was taken and it came back strongly positive In August 1929 she was given a series of twenty intravenous injections of arsphenamine two injections a week The dosage is not known In February 1930 she received a course of forty intravenous injections one week apart In June 1931 and in January 1932 she was given another series of twenty injections of arsphenamine again one week apart This makes a total of 100 injections (intravenous) from August 1929 to May 1932 all being arsphenamine according to the patient's story Several different doctors gave these treatments in various cities the patient only recently coming under my care She is sure that she has had no medication by mouth and no intramuscular injections and says that she had one course of mercury inunction sometime during this period A Wassermann test in June 1932 was negative and one taken in February 1935 and sent to two laboratories came back negative from both The question that now arises is this She is now two months pregnant and wants to know what the chances are of having a healthy child She suffered so much both from intravenous injections and from the reactions after each injection which made her feel miserable for twenty four hours or more after each one that she flatly refuses any more intravenous therapy and insists that she would rather run the risks of an abortion than have any more injections She might be persuaded to have some bismuth intramuscularly if this would assure her a healthy child For herself alone she would rather take the chances of future trouble than have any more injections of any kind The points I should appreciate your opinion on are these 1 The chances of her having a healthy child on no more treatment 2 If these are absolutely essential how much and what preparation would you recommend other than intravenous as this she refuses even to consider 3 What are the chances of her developing some form of tertiary lesions if she takes no more treatment? (She also refuses lumbar puncture because of an unfortunate experience) 4 Is it necessary for her to have some heavy metals now and if so what and how much? 5 Would prolonged medication by mouth of a mixture of iodides and mercury be of any real value? Except for being rather nervous and very worried as to what course to pursue the patient seems to be in excellent physical condition her heart blood pressure and so on all being apparently normal I will appreciate any information you may be able to give me Should you care to print this in any form will you kindly omit my name

M D Pennsylvania

ANSWER—The answer to this inquiry is based on the results reported in Cooperative Clinical Studies in the Treatment of Syphilis Syphilis in Pregnancy (Reprint 46, *Veneral Disease Information* U S Public Health Service)

A syphilitic mother should be given early and adequate treatment throughout every pregnancy whether her Wassermann reaction is positive or negative This statement may be augmented by saying that treatment received previous to conception is not an assurance that a nonsyphilitic child will ensue Likewise all pregnant syphilitic women should receive treatment throughout the pregnancy, the earlier in the pregnancy that the treatment is started, the higher is the incidence of nonsyphilitic children When treatment was started before the fifth month of pregnancy and consisted of not less than ten injections of an arsphenamine and ten injections of a heavy metal 91 per cent of the children born were nonsyphilitic

1 Sixty-two per cent of the syphilitic pregnant mothers with negative Wassermann reactions who were treated previously but not during this pregnancy gave birth to normal children

Accordingly, if the patient in the case cited is not treated, there is a 38 per cent chance that she will have a syphilitic child

2 Arsphenamine and a heavy metal, preferably a preparation of bismuth, should be given in alternation, with a minimum of ten injections, and preferably more, of each. One of the preparations of arsphenamine for intramuscular use, such as bismuth arsphenamine sulfonate or sulfarsphenamine, might be tried

3 About 4 per cent of the cases adequately treated during pregnancy showed clinical progression subsequently

4 The average pregnant syphilitic woman tolerates the arsenicals more satisfactorily than she does the heavy metals. Kidney complications were quite common from the heavy metals. Intramuscular injections of a bismuth compound in small doses every five days might be well tolerated. If a heavy metal is used, weekly urine examinations should be made

5 Medication by mouth has no place in the treatment of a pregnant syphilitic woman

HEAT AND POSTURE IN ARTERIAL HYPERTENSION

To the Editor—Where can I obtain information referred to by Dr Irving Cutter in his syndicated article on reduction of blood pressure by heat applied to the extremities? The same author refers to variations in pressure according to posture

F BRITTON LANGDON, MD Des Moines Iowa

ANSWER—The origin of the quotation in the article by Dr Irving Cutter was a report by R F Fox appearing in the *Lancet* (1 984 [April 27] 1935). It has been repeatedly reported that external heat, in the form of hot baths or otherwise, causes a reduction of the arterial tension through the induction of active cutaneous hyperemia. This is the converse of the reaction of the arterial tension to cold. Exposure of one extremity to cold (ice water) has been employed (Hines E A, Jr, and Brown, G E *Ann Int Med* 7 209 [Aug] 1932, and others) to determine the vasomotor lability. It is asserted that after a single hot bath the systolic tension falls as much as 15 mm and remains reduced for from two to six hours. Reduction of the diastolic tension is less notable and less persistent. In the management of hypertensive arterial disease such hydrotherapy is an adjunct to rest and to the lessurely existence at spas. The increased fluid intake encouraged at such watering places also is of value

Variations in arterial tension due to changes in posture are of minor importance except in certain instances of postural hypotension. In these patients there is a failure of the normal control of the arterial tension when they quickly change from the horizontal to the vertical position. Normally such change in posture is associated with a compensatory rise in the arterial tension to overcome the hydrostatic pressure of the column of blood to the head. Symptoms of cerebral anemia appear when the patient is vertical. Syncope, presyncope, vertigo or tinnitus frequently occurs soon after the erect position is assumed (Ganshorn, J A, and Horton, B T *Proc Staff Meet Mayo Clin* 9 541 [Sept 12] 1934)

FREQUENCY OF URINATION WITH ENLARGED PROSTATE

To the Editor—I am 61 years old weigh 222 pounds (101 kg) and am 5 feet 11 inches (180 cm) in height. I had a tonsillectomy ten or twelve years ago for arthritis with complete relief. The arthritis returned two years ago and was again relieved by the extraction of an abscessed tooth. Except for a good many attacks of influenza and a gastroduodenal inflammation nearly thirty years ago my health has been in the main good. But for the past twelve or fifteen years I have been annoyed by polyuria both nocturnal and diurnal. Urinalysis has never shown anything abnormal. It interferes so much with sleep at night that it has become a nuisance. There is some prostatic enlargement but the last test showed no residual urine. The polyuria is worse in winter than in summer as I perspire very freely in hot weather. I have always drunk a good deal of milk but not much water except in hot weather. I have tried solution of posterior pituitary and ergotamine with no results. Can you suggest something to better this annoying condition? Please do not publish name

MD Virginia

ANSWER—Frequency of urination at night in a patient aged 61 in whom there is some prostatic enlargement, can best be explained on the basis of the prostatic enlargement in spite of the fact that the patient does not show residual urine. In a certain number of patients who suffer from prostatic obstruction the symptoms are marked and residual urine is often absent. In other words, it is not necessary in every patient with prostatic obstruction to have residual urine

Polyuria as a general proposition is worse in winter than in summer. On the other hand polyuria at this time of life may be due to conditions other than prostatic enlargement, for instance, it may be due to stone in the bladder, stone or tones in the prostate, diabetes or nephritis. Therefore, the

patient should have a complete physical examination and if this is negative he should be examined with the cystoscope and the resectoscope and if this shows, as it probably will, intravesical or intra-urethral enlargement, the patient should consider having the obstruction removed by transurethral electroresection

Drugs, such as solution of posterior pituitary and ergotamine, will not help much if the trouble is due to the conditions mentioned

HEREDITARY SYPHILIS

To the Editor—In a family in which three or four children have hereditary syphilis the condition was discovered several years ago and Wassermann tests were all positive. Likewise the blood Wassermann reaction of the mother was positive. The history of infection before her marriage was then elicited. The condition was suspected in the children because of keratitis. They have all had two or more courses of anti-syphilitic treatment but of course still have positive Wassermann reactions. There are no demonstrable lesions of any kind. These children have been permitted to attend public school but recently a local doctor has registered strenuous objections to the children remaining in school because of the danger of infecting others. He has gone so far as to threaten to withdraw his own children from school if these children are permitted to attend. The question was brought to me as city school physician whether these children could infect others and whether or not they should continue in school. My opinion is that they are not a menace and cannot transmit the disease. Because of the situation that has arisen, however, they have been withdrawn from school pending investigation to determine whether or not they might be infective. It seems a pity that these children should be further handicapped by being denied the advantages of some education. Before I make a definite recommendation I want to be reasonably sure that I am doing the right thing. If you are in possession of any information that will be a guide in this case or if you can procure such information or direct me to reliable sources for this information I will greatly appreciate it

MD Utah

ANSWER—The decision that these children are not infectious is justifiable. The fact that they are of school age indicates that they are old enough to have the tardive type of congenital syphilis, which is noninfectious in practically all cases. After even a moderate amount of treatment the possibility of a tardive syphilitic person being able to transmit the disease is eliminated for all practical purposes. It is the practice in most pediatric hospitals to place most children with this type of syphilis in general wards and to permit them to intermingle with other patients there. It would seem unfair to take away from these children the opportunity for an education when there is not justification from past experience that they would in any way endanger the other children with whom they came in contact at school

ADAMS STOKES DISEASE

To the Editor—A woman aged 57 has experienced several syncopal attacks during the past year. The blood pressure is 240 systolic 90 diastolic. The pulse rate is 36. There is moderate arteriosclerosis. The urine shows a trace of albumin and an occasional pus cell. The remainder of the physical examination reveals nothing significant. I have made a diagnosis of Adams-Stokes disease. What procedure should I follow in treating her? Would you advise the use of barium chloride or atropine in the free of the systolic reading? MD North Carolina

ANSWER—The diagnosis probably is quite correct. This could be conclusively proved by observation during the attack of syncope. In typical Adams-Stokes disease the syncopal period is associated with a total absence of systolic sounds (soft muffled auricular beats may occasionally be heard). Electrocardiographic evidence of ventricular standstill is corroborative proof. Syncopal attacks of vagus origin, which may simulate Adams-Stokes disease, are usually brief and occur more frequently in younger persons. The symptoms can be induced by pressure on the carotid sheath

Of great interest is the enormous pulse pressure. This in itself is indicative of chronic heart block, for the systolic pressure is quickly but persistently increased in hypertensive arterial disease on the occurrence of heart block. The exact mechanism of this phenomenon is uncertain

The use of atropine (0.001 Gm) or tincture of belladonna (1 cc) is not contraindicated by the systolic hypertension. It is essential to depress, so far as possible, the vagal effects, which may enhance the bradycardia. Atropine may be wisely administered to the point of tolerance. Barium chloride is used for the purpose of stimulating the ventricular pacemaker, and its use is justified. Ephedrine hydrochloride and/or epinephrine have also been so employed, but their notable vasoconstrictor activity strongly contraindicates their use

More logically employed are vasodilators, which may aid in improving the coronary circulation. The presence of arteriosclerosis is not a coincidence, for the interference with the conduction of the cardiac impulses is unquestionably due to

myocardosis secondary to impairment of the coronary circulation and hypertensive arterial disease. Reduction of the cardiac burden by reducing the peripheral resistance to the circulation through systemic reduction of the arterial tension should serve to aid the handicapped myocardium. Such vasodilators include aminophylline, soluble nitrite, the alkyl nitrates and bismuth subnitrate. If aminophylline is well tolerated (gastric irritation is best avoided by solution of the tablet before administration) it may prove of considerable value. The soluble nitrites or the alkyl nitrates are best employed in very small doses at frequent intervals, for their effects are only transient and tolerance may be acquired. Bismuth subnitrate may be administered in doses of 0.6 Gm. three times a day for many weeks as a prophylactic arterial sedative, which often diminishes the frequency and severity of anginal attacks. Adams-Stokes disease is in many essentials a form of angina pectoris.

The ultimate prognosis is precarious. Death may occur in acute syncope from ventricular standstill or with intense cardiac pain from further interference with the coronary circulation. Death by congestive cardiac failure is exceptional in Adams-Stokes disease. Activity should be minimal and attention to nutrition, anemia and general physical health not neglected.

DIPHTHERIA ANTITOXIN BEFORE POSITIVE CULTURE

To the Editor—I was called to see a patient aged 14 suffering from sore throat difficult breathing respiration 32 to 45 per minute temperature 103 F general prostration and pulse rate 140-160 weak and thready. Physical examination revealed an extensive dirty white pseudo-membrane over the tonsils uvula and nasopharynx. The lungs were negative for pneumonia. The abdomen was normal. The patient presented clinical symptoms and signs of diphtheria however as there was no other case of diphtheria in the community I gave digitalis one half grain (0.03 Gm.) of codeine sulfate 5 grains (0.3 Gm.) of sal. ethyl carbonate and a hexylresorcinol gargle. Within a few hours I was again called and found the patient worse. This time I gave 40,000 units of diphtheria antitoxin. The patient began to improve the membrane disappeared and the patient recovered with no ill effects. My pay is being refused because I did not get a report from the state laboratory before giving the antitoxin. I am 250 miles from the state laboratory and my practice is in the woods. I maintain that to have waited would have placed the patient's life in jeopardy and if the patient had not died would have had impaired heart nephritis and so on. Was it proper for me to give diphtheria antitoxin immediately or should I have waited from thirty six to forty eight hours for a laboratory report? I was formerly resident physician at Sydenham Hospital for Contagious and Infectious Diseases and while there saw many deaths due to delay in giving diphtheria antitoxin before patients came to the hospital. Please omit name.

M D Wisconsin

ANSWER—The physician should be commended for prompt administration of diphtheria antitoxin. Ordinarily the laboratory should be relied on only to confirm the clinical diagnosis. It is unfortunate that such valuable service was not appreciated.

HYPERTHERMIA IN PARALYSIS AGITANS

To the Editor—I have been appealed to by a former patient as to the advisability of taking the hyperthermia treatment for Parkinson's disease. Having observed the results in a few cases of infectious origin I refrained from speaking my mind until I could consult an unbiased authority hence this letter to you. This is an advanced case of Parkinson's disease and I felt that a prolonged maintenance of a high body temperature could only do harm. The operator asks \$100 for eight treatments of five hours duration each. Whether this is the chief therapeutic indication I am unable to say. Please reply as promptly as possible.

M D Illinois

ANSWER—No logical reason for the use of fever therapy in Parkinson's syndrome has yet been presented in the medical literature. No carefully controlled clinical study in a large group of cases has yet been set forth.

In the letter of inquiry it is not stated whether the advanced Parkinson's syndrome is senile or postencephalitic.

W H Schmidt, an exponent of fever therapy in the treatment of Parkinson's syndrome has merely recommended it in the postencephalitic type (Fever Therapy and Other Recent Developments in Physical Therapy, *New England J Med* 209:419 [Aug 31] 1933). There is apparently no particular reason to use it in the senile type, in fact it may be quite dangerous to use fever therapy for an aged individual. The Council on Physical Therapy has pointed out that in the administration of hyperpyrexia produced by physical agents, "advanced age (with a few exceptions 60 years may be taken as an arbitrary limit)" should be regarded as an "absolute" contraindication (Hyperpyrexia Produced by Physical Agents *The Journal*, Oct 27, 1934 p 1308).

In the postencephalitic group, Schmidt's statement that "we have also treated a number of cases of postencephalitis showing

the parkinsonian syndrome with marked improvement in quite a few" is so vague that it can carry little weight. In at least one clinic careful studies in four cases have revealed no significant beneficial effects when fever treatments were given.

Until a satisfactory series of controlled clinical studies in at least 100 cases is presented in the literature, either to confirm or to refute the statement of Schmidt, no final conclusion can be drawn.

In the meantime it would probably be best to heed the statement of David Riesman that "fever therapy in the form of diathermy or malarial or bacterial injections seems to produce no permanent benefit. It may even do harm" (*Encephalitis Lethargica*, *Ann Surg* 101:303 [Jan] 1935).

INSTRUMENTS FOR MASSAGE OF PROSTATE

To the Editor—In the issue of Dec 21 1935 in the answer to the query on emptying seminal vesicles an instrument was mentioned to be attached to the index finger for massage of the prostate and vesicles. Will you please let me know the name of the concern making the instrument? My index finger is rather short and I have difficulty reaching the upper borders of the vesicles.

B W W M D New York

ANSWER—There are two such instruments. 1 Eastman Masseur, made by the Eastman Company, Indianapolis. This is a long hollow tube with a curved knob at the tip. The finger fits snugly into the lower end. There are two slits along the sides at the base to allow for different size fingers. 2 The Leusman, which consists of a long curved hollow metal tube that fits the finger. There is a handle attached to the open end which fits into the palm of the hand and allows for a grip on the instrument. This instrument is not available.

DEFICIENCY OF BEARD

To the Editor—What will stimulate the growth of a beard in a man aged 23 otherwise normal? Please omit name.

M D Wisconsin

ANSWER—The absence of hair growth in the beard in a man of 23 usually has some endocrine basis. These cases often show other evidences of endocrine deficiencies, such as sparsity of hair in the axilla and pubic area, underdeveloped genitalia and voice changes.

There should be a basal metabolic determination for thyroid deficiency. If there is any present, thyroid may be given, or it may be given empirically. While anterior pituitary substance by mouth or injection may be used, its value in the promotion of hair growth is questionable.

Council on Medical Education and Hospitals

ADDITIONAL HOSPITALS APPROVED

The Council on Medical Education and Hospitals of the American Medical Association has given its approval to the following hospitals since the publication of the last previous list in *THE JOURNAL*, Dec 28, 1935.

Hospitals Approved for Intern Training

Homoeopathic Hospital Wilmington Del
Henrotin Hospital Chicago
Rex Hospital Raleigh N C
Fitzgerald Mercy Hospital Darby Pa
Homeopathic Medical and Surgical Hospital Reading Pa
St Mary's Hospital Superior Wis

Hospitals Approved for Residencies in Specialties

Grady Hospital (White Unit) Atlanta Ga. Medicine obstetrics gynecology ophthalmology otolaryngology and surgery
Wesley Memorial Hospital Chicago. Medicine and surgery
Free Hospital for Women Brookline Mass. Gynecology
State Hospital No 4 Farmington Mo. Psychiatry
City Memorial Hospital Winston Salem N C. Medicine and surgery
Toledo State Hospital Toledo Ohio. Psychiatry
St Elizabeth's Hospital Youngstown Ohio. Medicine and surgery
Children's Hospital Chattanooga Tenn. Pediatrics
Chesapeake and Ohio Railway Hospital Clifton Forge Va. Mixed

Hospitals Approved for Additional Residencies

Gallinger Municipal Hospital Washington D C. Urology
Hurley Hospital, Flint Mich. Surgery
Kings County Hospital Brooklyn. Neurology
Millard Fillmore Hospital Buffalo. Obstetrics
Bellevue Hospital New York City. Anesthesia
Charity Hospital Cleveland. Pathology
Starling Loving University Hospital Columbus Ohio. Gynecology
St Francis Hospital Pittsburgh. Obstetrics gynecology
Roper Hospital Charleston S C. Radiology

Arkansas November Examination

Dr A. S. Buchanan, secretary, State Medical Board of the Arkansas Medical Society, reports the written examination held in Little Rock Nov. 12 13 1935. The examination covered 12 subjects and included 120 questions. An average of 75 per cent was required to pass. Two candidates were examined both of whom passed. The following school was represented:

School	PASSED	Year Grad	Per Cent
Tulane University of Louisiana School of Medicine	(1935)	97.5	87

Nine physicians were licensed by reciprocity and 1 physician was licensed by endorsement from May 20 through October 21. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad	Reciprocity with
Northwestern University Medical School	(1934)		Illinois
Kansas City Medical College Missouri	(1892)		Kansas

School	Year Grad	Endorsement of
Memphis Hospital Medical College	(1909)	Tennessee
Univ. of Tennessee Col. of Med.	(1928) (1932) (1933)	Tennessee

University of Pennsylvania School of Medicine	(1927)		Penna.
University of Texas School of Medicine	(1931)		Texas

Book Notices

Diet and Physical Efficiency. The Influence of Frequency of Meals upon Physical Efficiency and Industrial Productivity. By Howard W. Haggard M.D. and Leon A. Greenberg Ph.D. of the Department of Applied Physiology in Yale University. Cloth Price \$3. Pp. 180 with 31 illustrations. New Haven: Yale University Press. London: Oxford University Press. 1935.

This well written monograph deals with that much neglected aspect of human nutrition the quantitative distribution of the daily diet into meals. It comprises the report of a well conceived and carefully executed piece of research and also presents sufficient of the fundamental physiologic background to make the results and conclusions available to the general reader as well as to the trained physiologist. The work was based on the initial premise that the distribution of the food intake among the conventional three meals a day is largely a matter of national habit and is determined by economic necessity and social usage rather than by scientific principles of nutrition. The object of the research was to discover the best meal time interval and to establish the scientific principles for its being. After demonstrating proper criteria in the laboratory and devising a suitable method for their application in industry, the authors were able to show that 'a high muscular efficiency is the objective and measurable accompaniment of a subjective feeling of well being and vigor, and that the rise and fall of this efficiency is correlated also with the rise and fall of productivity among factory operatives performing manual tasks.' From their observations on the muscular efficiency and the 'pattern of productivity' of industrial workers engaged in the tasks at which they ordinarily earned their livelihoods, the authors have concluded that the usual practice in this country, of eating the day's supply of food in three installments does not permit the greatest vigor and efficiency of which the individual is capable. Five meals a day (the total amount and quality of the food remaining the same) yields the maximum efficiency. This volume should be of particular interest to employers of labor as well as to students of nutrition.

High Blood Pressure and Its Common Sequelae. By Hugh O. Cunningham M.B. B.S. D.M.P.P. Cloth Price \$3. Pp. 172 with 11 illustrations. Baltimore: William Wood & Company. 1935.

This small volume presents a brief sketch of the major aspects of hypertensive disease. It cannot be classed as a comprehensive monograph. It reflects throughout the British background of the author and presents some original and apparently heretofore unpublished studies on the relationship of the arterial tension to habits of life. The observation that the average arterial tension of the rickshaw men, or 'runners,' is notably

lower than the average for others of similar race but of most sedentary habits is interesting and thought provoking. The discussion of the etiology of hypertensive arterial disease is all of the book, is remarkable for its unbiased sanity but is wholly incomplete. The presentation of the cardiac phenomena of hypertension is concise and clear. The analysis of the problems of renal function impairment as it occurs in hypertension merely touches the surface and leaves out much that should be incorporated. The description of the proper technique of sphygmomanometry is adequate and precise. The author's emphasis on the importance of the diastolic tension early in the book is well made, but he does not follow this concept further along. To be reminded of the frequency of hypertension in the tropics is of value for we are prone to take a somewhat provincial attitude against the American emphasis on hypertension. The author writes clearly and well. Where he has some original concept to present there appears enthusiasm and conviction that are lacking elsewhere. The chapters on apoplexy and on pulmonary edema are unusually well written. The book, although apparently intended for general consumption, appears to be too brief and sketchy to yield a really clear picture of hypertensive arterial disease to those whose work has not dealt extensively with the problems. For the internist it has little to offer that is new. More comprehensive American monographs, such as Fishberg's "Hypertension and Nephritis" (Lea & Febiger) and Steglitz's "Abnormal Arterial Tension" (National Medical Book Company), cover the subject more fully and with perhaps a better placement of emphasis.

Malyariynaya terapiya nevrolyuesy i drugikh zabolevaniy nervnoy sistemy [By] P. A. Vinlovich. Iz khimii i nervnykh bolezney Rostovskogo n. D. Meditsinskaya i kraevogo neuro-psikhiatricheskogo Instituta. [Material Therapy of Neurosyphilis and Other Diseases of Nervous System]. Cloth. Pp. 200 with illustrations. Azov-Chernomorsk Regional Publishing Company. 1934.

This, the first monograph on the subject in the Russian language, presents an exhaustive discussion as well as an analysis of the author's experience with the method of malarial therapy. The author discusses indications, contraindications, the choice of the parasite, the technique of inoculation, the course of experimental malaria and the methods of terminating it. From ten to twelve paroxysms constitute one course. The literature concerning the results obtained in dementia paralytica is critically reviewed. The author's impressions are based on an experience with 1,000 cases treated by him in the last seven years. Of this number he was able to study and follow up 712 cases for from one to eight years. He feels that both the specific and the nonspecific therapy are indicated in the post-syphilitic diseases and in the refractory early cases of syphilis. Of the nonspecific agents he considers malarial therapy to be the most effective. Best results in dementia paralytica and in locomotor ataxia will be accomplished by an early diagnosis and timely application of malarial therapy. For some of those cases repeated courses of malaria will be advisable. The parasite best suited for repeated courses is the quartan. The effect of malarial therapy in nonsyphilitic diseases of the nervous system requires further observations. One might expect some improvement in cases of epilepsy with a syphilitic etiology and in the early cases of schizophrenia. The author stresses the necessity of establishing special centers for the rational application of malarial therapy and the study of associated problems. The appended exhaustive bibliography enhances the value of this excellent monograph.

A B C of the Endocrines. By Jennie Gregory, M.S. Foreword by Carl G. Hartman, Department of Embryology, Carnegie Institution of Washington. Cloth. Price \$3. Pp. 126 with illustrations. Baltimore: Williams & Wilkins Company. 1935.

The distinctive feature of this volume is the absence of text, the entire material being presented in charts and graphs. The diagrams and legends comprise a novel and interesting attempt to review in a simple and concise manner, the present status of endocrinology for the benefit of the general practitioner, the medical student and the intelligent layman. This method of presenting the hormone activities, the functional interrelationships of the various glands and the commoner glandular disorders compresses a remarkable amount of factual material and hypothesis into a small space. The method, however, does not lend itself to the ready distinction between fact and theory nor

does it allow for the use of the many reservations with which much of our present knowledge must be seasoned. The author has apparently made every effort to avoid misrepresentation by basing her material on the works of the acknowledged authorities in the field. Those who use this book for the purpose for which it was designed should find it extremely interesting and useful. It is not, however, intended to be a diagnostic or therapeutic manual, and practitioners who may be tempted to use it as such should be reminded, in the words of Pope, that "a little learning is a dangerous thing."

Lehrbuch der Gynäkologie. Von Prof. Dr. W. Stoeckel, Geh. med. rat. Direktor der Universitäts-Frauenklinik zu Berlin. Fifth edition. Paper. Price 33 marks. Pp. 760 with 531 illustrations. Leipzig: S. Hirzel. 1935.

The book primarily written by Fritsch has been so completely gone over by the present author, who wrote five editions, that it bears no resemblance to the original work either in text or in its external appearance. As in previous editions, the operative technique is considered by the author as beyond the scope of the book. In addition to having all the good qualities of the preceding edition, the present one may rightly boast of a painstaking revision of chapters on menstruation, uterine cancer, heat and light treatment, conception, sterility, methods of sterilization and female hygiene. Numerous new illustrations have been added. The constructive criticism may be limited to a few remarks. Little is said about trichomonas vaginitis, the treatment of this condition is not discussed separately, the author apparently applying the same therapy in any kind of vaginitis. The modern appliances for colposcopic examination are not described. The subject of lymphogranuloma inguinale is too briefly treated. One is disappointed with the bare mention of granuloma inguinale. The use of proprietary drugs not popular in foreign countries is regrettable from the point of view of non-German readers. One may deplore the paucity of discussion of the relations between the genital system and the various endocrine glands. Reproduction of photographs of nude patients with faces uncovered is not in keeping with good taste, at least according to views prevailing in the American literature. Except for a few such shortcomings, the book excels in every respect, especially the chapters on uterine cancer and myomas, ovarian cysts and tumors are real masterpieces. The various subjects throughout the book are presented in a clear, concise manner, the style is fluent, terse and easily readable. The book is replete with high grade illustrations and beautiful reproductions in color. The author's attitude toward the treatment of cancer of the cervix deserves attention. He advocates preoperative radium treatment and postoperative applications of x-rays and advises a surgical removal of the cancer because some tumors are radioresistant. He prefers Schuchardt's vaginal extirpation of the uterus to an abdominal hysterectomy. The chapter on x-rays has been written by Mikulicz-Radecki. This most modern and thorough book on gynecology is well worth adding to one's library.

The Bacteriology of Typhoid, Salmonella and Dysentery Infections and Carrier States. By Leon C. Havens, M.D., Director of Laboratories, Alabama Department of Public Health. Edited by Kenneth F. Macey, M.D. Foreword by Wilson G. Smillie, M.D. Cloth. Price \$1.75. Pp. 158 with 6 illustrations. New York: The Commonwealth Fund. London: Oxford University Press. 1935.

In this small volume the author has described his experience in those fields which were his main interests as director of the Alabama state laboratories. It is exceedingly regrettable that Dr. Havens' death occurred to end his work so early in life and before the publication of this useful handbook. The publishers are to be congratulated, however, on having the material presented under the editorship of Dr. Kenneth F. Macey. The various subjects discussed in the thirteen chapters are of particular interest to the laboratory worker and to the field epidemiologist whose work involves the investigation of these problems. To these workers especially the volume will serve a useful purpose as a reference handbook, since the author stresses the importance of the standard techniques and procedures accepted by most public health laboratories. While the review of the carrier problem and its relation to the control of typhoid is not as complete as one would desire, it does include a discussion of the most important aspects and particularly those applicable to the problem as it affects the Southern states. The considera-

tion of the Salmonella group is reasonably complete, giving emphasis to many laboratory and epidemiologic points incident to the full discussion of the bacteriology of this interesting and intricate group of "food poisoning" organisms. Undoubtedly this laboratory and field manual will be widely used not only by those investigating the related problems in the laboratory and in the field for state and local health departments but also in the field of medical education since the presentation is clear, concise and accurate thereby making the volume suitable for teaching purposes. The format is attractive and the paper and printing are excellent, in the usual manner of Commonwealth Fund publications, all making for a volume that is inviting to the reader.

Glands and Efficient Behavior By Florence Masteer Ph.D. Director Merryheart Clinic Merryheart Schools Columbus Ohio. With an introduction by Max A. Goldzieher M.D. Endocrinologist of the Gouverneur Hospital New York. Cloth Price \$2.50 Pp 213 New York & London D Appleton Century Company Inc 1935

This is an enthusiastic dissertation, intended for lay consumption, on the relation of endocrine deficiencies to behavior problems in children and adults. The author is a psychologist who exhibits a commendable degree of skepticism in her own field. However, this critical attitude is not carried through the book, many unexpected lapses in judgment occur, particularly when the author invades little known territory in the realm of endocrinology. Many case histories are included these add to the interest but unfortunately not always to the scientific value of the treatise. Some of the therapeutic measures employed, such as calcium feeding and the administration of vitamin D bear a questionable relation to the subject of the book. The author appears to have more faith than present knowledge warrants in the oral administration of such glandular products as desiccated pituitary or parathyroid. While it contains some sound and valuable information, this volume will probably serve to mislead quite as much as to inform the unwary reader.

Diet Manual St Mary's Hospital Compiled by Sister Mary Victor R.N. B.S. Director of the Department of Nutrition St Mary's Hospital Rochester Minnesota. Second edition. Cloth Price \$2.50 Pp 191 Rochester Minn. St Mary's Hospital 1935

This edition, revised by Sister Mary Victor, constitutes a well organized outline of present-day diet therapy and is useful both to the doctor and to the dietitian. The organization of material has as its central idea the "optimum diet," with the therapeutic diet as a modification that still supplies all the nutritional essentials. Diet therapies for adults and those for children are treated in separate sections. The author has divided her material according to the conditions of disease which require treatment by diet. She outlines the general principles underlying the choice of food for each condition and lists the foods that may be used. A menu outline indicates how the average nutritive requirements may be satisfied with the foods allowed. Recipes for dishes suitable for diabetic diets are particularly helpful to the doctor or the dietitian who is looking for some ways to add variety to an otherwise rigid regimen. The material is well indexed and with the tables in the appendix it serves as a useful and compact manual of diet therapy.

Cardiac Output and Arterial Hypertension By Sidney A. Goldstone M.D. Cloth Price \$1.15 Pp 56 with illustrations New York The Author 1935

This little volume is a collection of four individual papers rather than a monograph dealing with the subject as a whole. The first two papers present a critical outline of methods of determining the cardiac output in man by foreign gas inhalation. The third paper deals with an application of the author's modification to a study of the cardiac output in arterial hypertension. It is shown that the cardiac output is normal in the hypertensive state and that therefore it is concluded that the increased cardiac work which results in hypertrophy may be attributed solely to increased peripheral resistance. The fourth paper is a scholarly, critical analysis of the literature dealing with the pathogenesis of nephritic hypertension no new facts are presented. The philosophical discussion is interesting reading although many assumptions make one question the validity of the conclusions. For those deeply interested in investigative work on circulatory dynamics the book is worthy of study. It is not applicable or intended for general reading.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice Ischemic Paralysis Following Fracture of Humerus—Dr Weeks, one of the defendants in this case, while visiting a patient in a hospital was asked to treat the plaintiff, a 6 year old child who had just been brought in in an emergency, because of an injury to her left arm. He diagnosed the injury as a fracture of the bone just above the elbow joint, reduced the fracture, and immobilized the arm with the elbow joint acutely flexed and the forearm supinated. The forearm was bandaged to the upper arm by 2-inch adhesive tape and was fastened to the chest wall with a sling made of the same material. Dr Weeks' services then ended, and the patient was returned to her home. From a dissenting opinion in this case, it appears that before the patient left the hospital Dr Weeks notified her mother of the danger of swelling and instructed her to notify her own physician at once if it occurred, and there is nothing to indicate that he did not do so.

During the night following the injury, the arm became swollen and painful, and on the following day the patient's parents called in Dr Salomon. He examined the arm and had roentgenograms made but apparently did nothing more. That night, because of the continued swelling of the arm, the patient's mother on her own initiative cut the bandage, but not completely through. The following day, on Dr Salomon's advice, she released the bandage and placed the patient's arm in a loose sling. On the third day after the injury a specialist, summoned at the instance of Dr Salomon, found that ischemic paralysis had developed. Blood blisters appeared at the wrist and elbow, and the tissues at those sites were infected, suppurated and sloughed. At the time of the trial, one and one-half years after the injury, the muscles had wasted and hardened so that the patient could flex her elbow only 90 degrees and her thumb 10 degrees, and her fingers were powerless. She presented the usual deformity incident to ischemic paralysis of this type and there was no possibility of improvement by medical aid.

Through a guardian appointed for that purpose, the patient sued both Dr Weeks and Dr Salomon. She made no complaint of Dr Weeks' diagnosis and reduction of the fracture, nor did she allege that he did not have the requisite skill and learning. Her sole complaint was that he was negligent in the application of that skill and learning in the treatment of her injury. The jury returned a verdict exonerating Dr Salomon and awarding damages against Dr Weeks. Dr Weeks thereupon appealed to the district court of appeal, first district, division 1 California.

In the course of the trial, to support her charge of negligence on the part of Dr Weeks, the plaintiff introduced the testimony of only one medical expert. He interpreted the roentgenograms that had been taken as showing that the elbow joint had been flexed as far as it could possibly go under pressure, that the forearm had been placed against the upper arm as close as it would go without being heavily forced, and that the bandage was too tight. On behalf of the physician-defendant, Dr Weeks two roentgenologists testified that the roentgenograms showed a degree of flexion usually used in the treatment of fractures such as the plaintiff had and that there was no undue pressure from the bandage. The opinion of the sole medical expert introduced by the plaintiff was further contradicted by the testimony of five medical experts and of the defendant Weeks himself. The defendant Weeks argued that he was not chargeable with negligence since the course he had pursued was approved by many experts and disapproved by only one. But the difference in the number of witnesses said the court, is a false quantity, since, under the California Code of Civil Procedure, "the direct evidence of one witness who is entitled to full credit is sufficient for proof of any fact," and the jury "are not bound to decide in conformity with the declarations of any number of witnesses, which do not produce conviction in their minds against a less number."

The defendant Weeks contended further that the plaintiff's medical expert witness had invaded the province of the jury when he stated his opinion as to the cause of the plaintiff's paralysis. But, said the court, quoting with approval *DeGroot v Winter* 261 Mich 660, 247 N W 69

When a result may or may not be occasioned by malpractice an expert medical witness invades the province of the jury when permitted to go beyond stating that it *could* and in saying that it *did* occasion the result. Such an opinion is but the private judgment of the witness and not competent evidence. Whether the alleged malpractice could occasion the result complained of was one of science only. Whether malpractice did occasion such result was in the controversy and therefore not one of mere science. When the facts are admitted and not in dispute the question if answered may be considered one of science. But when a result could have been occasioned by one of two or more causes the ultimate fact of which cause occasioned the result is for determination by the jury and a medical expert may not in case of conflicting evidence invade the province of the jury and testify that the result was in fact occasioned by one cause only.

The appellate court could find nothing in the record to show that the plaintiff's expert witness had transgressed the rule thus laid down.

The defendant claimed that the trial court erred in admitting in evidence, over his objection, enlargements of the roentgenograms that were taken. In rejecting this claim, the appellate court quoted 22 C J 918, as follows:

It is no objection to the admissibility of a photograph that it is enlarged showing the subject or object magnified where this does not have a tendency to mislead. Photographs of instruments already in evidence which are so enlarged as to make the proportions plain and to illustrate the testimony of the witnesses may go to the jury in the same way as would a magnifying glass or microscope.

It is for the trial court to determine from the evidence before it whether enlargements of photographs already in evidence are correct representations thereof, and its ruling will be sustained unless it is apparent that there has been an abuse of discretion. Moreover, conceding that the enlargements in this case exaggerated and distorted the alignment of the bones, the defendant was not thereby prejudiced since there was no dispute as to the reduction of the fracture and no claim is made that the enlargements had a tendency in any other respect to mislead.

In the opinion of the appellate court, the nature and extent of the injury to the tissue, muscles and blood vessels of the patient's arm at the time of the fracture and the progressive development of injury to those parts following the emergency treatment given by the defendant Weeks, not only supported the jury's conclusion that paralysis was caused by trauma, arising from the treatment, but negated a conclusion that the paralysis developed pathologically and from internal pressure. The judgment of the trial court was therefore affirmed. The presiding justice, however, filed a dissenting opinion, concluding that the judgment was without evidentiary support and should be reversed.—*Sims v Weeks (Calif)* 45 P (2d) 350

Death from Hemolytic Streptococcal Infection Attributed to Debility Following Trauma—Deceased was struck by an automobile driven by the defendant May 31, 1930. She had a miscarriage and subsequently, notwithstanding treatment she had prolonged hemorrhages, became anemic, and lost vitality and strength. She was taken to a hospital Feb 12, 1931. According to the report of the case she was not infected by hemolytic streptococci when she entered the hospital but was so infected while there. What the portal of infection was and the nature of its manifestation, the reported decision does not show. The first manifestation of infection appeared however February 17. The patient died Feb 19, 1931. Her husband thereupon sued the defendant charging him with liability for the death of the plaintiff's wife, because of the automobile accident eight and one-half months earlier.

There was medical testimony to show that a causal relation existed between the accident and the death, based on the theory that the hemorrhages from which the deceased suffered were caused by the accident and that they so lowered her vitality that she could not resist the subsequent infection by streptococci. The trial court charged the jury that they would be justified in finding that there was a causal relation between the accident and the death if they found that the accident caused

the hemorrhages, that because of those hemorrhages the deceased's vitality was impaired and her capacity to resist disease weakened, and that because of that lowered vitality infection by hemolytic streptococci occurred and caused death. The jury so found and returned verdicts in favor of the plaintiff in each of the several suits instituted by him. From these verdicts the defendant appealed to the Supreme Judicial Court of Massachusetts.

The defendant contended that the injury suffered as a result of the automobile accident was not legally the proximate cause of death. But, said the Supreme Judicial Court, a cause which in a continuous sequence, unbroken by any new cause, produces an event, and without which cause that event would not have occurred, is a proximate cause. It may be assisted or accelerated by other incidental and ancillary matters, but if it continues as an operative potent factor, the course of causation is not broken. If any injury progressively so reduces the general vitality of an injured person as to make him peculiarly susceptible to a disease which he contracts, the chain of causation, as a matter of law, is not broken.

If the negligent actor is liable for another's injury which so lowers the other's vitality as to render him peculiarly susceptible to the disease the actor is also liable for a disease which is contracted because of the lowered vitality.—2 *Am. Law Inst. Restatement Torts* Sec 458

The Supreme Judicial Court regarded the case as close, but in its opinion it could not quite be said that there was no evidence to support the verdicts of the jury. Accordingly, it allowed the verdicts in favor of the plaintiff to stand.—*Wallace v Ludwig (three cases) (Mass)*, 198 N E 159

Current Medical Literature

AMERICAN

The Association Library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1926 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Prophylaxis of Rickets in Premature Infants—Davidson and his associates gave eleven premature infants vitamin D milk, from cows fed irradiated yeast, during the first six months of life to determine how far they could be protected from rickets by this means alone. Clinical evidence of rickets was slight and when present appeared about a month later than it was noted in the roentgenogram. In only one instance was the calcium-phosphorus value found to be definitely lowered. By roentgenogram, two of the infants remained free from rickets throughout the period of study, the other nine showed rickets of mild degree from the third to the fifth month which had satisfactorily healed by the sixth month without a change in the antirachitic regimen. Vitamin D milk, when used in routine feeding as the sole antirachitic substance, is shown to be inadequate for the complete protection of the premature infant against rickets.

Creatinuria of Infancy and Childhood—Marples and Levine made a study of physiologic creatinuria and the influence of extraneous factors on such creatinuria in eight normal infants aged from 3 weeks to 7 months. The composite data were collected from a total of 129 days and gave the following results: 1. All the infants excreted creatine in the urine the creatine coefficients (mg. of nitrogen per kilogram of body weight in twenty-four hours) varying from 0.3 to 5.14. The coefficients ranged from 374 to 578 with an average of 493. The total creatine coefficients (creatinine plus creatine) ranged from 482 to 105, with an average of 886 for the group of infants more than 1 month of age. 2. Age appeared to have no influence on the excretion of creatinine within the limited age range studied. Premature infants excreted practically no creatine, and this was also true for some very young full term infants. 3. Creatinuria of infants could be diminished by feeding diets low in protein but of adequate caloric value. It could be increased by feeding diets high in protein. The excretion of creatinine was not materially affected by these changes in diet. 4. Infants have a low tolerance for ingested creatine. From 55 to 65 per cent of the amount ingested was excreted in the urine as creatine in the first twenty-four hours and from 63 to 82 per cent in forty-eight hours. 5. The ingestion of aminoacetic acid increased the spontaneous creatinuria of infants but had no effect on the excretion of creatinine. Only a small fraction of the ingested aminoacetic acid was represented in the extra creatine excreted, and there was no specific quantitative relationship between the amount of aminoacetic acid ingested and the extra creatine excreted. 6. The ingestion of

sodium benzoate causes an initial increase in creatinuria, perhaps because of the increased protein metabolism caused by the benzoate, followed by a decrease to below the foreperiod level. The authors state that the study forms a background for an investigation of the effect of endocrine products on creatinuria, which will be reported subsequently.

Seventh Nerve and Transmission of Poliomyelitis—Toomey states that although the virus of poliomyelitis may be absorbed by any gray nerve fiber, the production of the clinical condition depends on the size of the absorbing nerve fiber and the nearness of it to the central nervous system. Although the skin contains gray fibers, it would take thousands of minimal paralyzing doses of the virus to produce the effect that a single dose of the same amount would produce after intracerebral injection into a monkey. The length of the chorda tympani nerve, the small size of this nerve, the fact that it is medullated and its devious course to the medullary area are factors that would tend to retard the virus from spreading to the medullary area. Many taste buds might absorb the virus and yet the disease might not be produced since the virus might be absorbed and its spread checked somewhere between the peripheral absorbing area and the nucleus of the nerve. Obviously, there are fewer cases in which the seventh nerve is involved than there are cases in which the spinal nerves are involved. Experimentally, however, such an entity can be produced in the *Macacus rhesus* monkey. This method of spread is not entirely hypothetical since the author has produced the same condition experimentally in the *Macacus rhesus* monkey when this avenue of approach was used. It is only when the virus can approximate the gray fibers by dilating the intestine that the disease follows. Many things may cause natural distention. Analogously, although he punctured the taste buds to achieve his purpose, he was able to demonstrate a condition in the experimental animal similar to that which appears in the human being. He concludes that the production of the isolated paralyzes of the muscles of the seventh nerve that occur as a result of poliomyelitis can be best explained by assuming that the point of entry is by way of the gastrointestinal tract, in this instance the gustatory fibers.

Brain Tumors in Children—Scott names gliomas, congenital tumors and tuberculomas as the three types of tumors occurring in children and divides the gliomas into spongioblastomas, medulloblastomas and astrocytomas. He states that in the differential diagnosis one must rule out brain abscess,

when there is a history of trauma, ear or mastoid operation, or sinus infection with or without operation, by the acute onset, increase in temperature and a leukocytosis. When vomiting occurs daily or at fairly frequent intervals, gastro-intestinal disturbances must be ruled out. The same applies to eye strain. This will sometimes cause morning vomiting. An eyeground examination should be insisted on when the eyes are being tested. If, on spinal puncture, the fluid shows old blood, one may suspect a hemorrhagic pachymeningitis, or, if fresh blood is present, the history should be studied carefully for trauma. When a child presents a gradual increase in irritability from no known cause, such as overfatigue, it is well to study the history carefully. A complete physical examination must be made, including a study of the eye and the eyegrounds. If a child who has been apparently normal becomes awkward in the use of his arms or legs, chorea must be considered and ruled out. Here there are usually the involuntary movements so characteristic of chorea. In the brain tumor case, the awkwardness varies when voluntary movements are attempted. Gastro-intestinal disturbance of a chronic nature may be suspected from the vomiting and headaches. Here too the careful history and physical examination and in addition possibly a roentgen study of the gastro-intestinal tract will help clarify this. The prognosis is always poor. Medulloblastomas are highly malignant and spread through the spinal fluid, where they become implanted in the spinal spaces. They are radiosensitive. The postoperative clinical course is from six months to five years. Treatment is surgical, followed by high voltage roentgen therapy in the case of medulloblastomas. The surgical mortality is high. A decompression may relieve the symptoms for a while.

- *Pneumothorax Therapy in Lobar Pneumonia. T. J. Abernethy, F. L. Horsfall Jr. and C. M. MacLeod. New York—p. 35.

Neurosyphilis—Kemp and Menninger base their remarks on a study of 680 patients, in whom all necessary data are given and of whom 265 had neurosyphilis. 1. Early inadequate treatment (given within two years after infection) apparently does not increase the incidence of neurosyphilis; with no treatment, neurosyphilis comprises 52.6 per cent of cases, and with early inadequate treatment it comprises 43.4 per cent of cases. 2. The incidence of neurosyphilis in males with no or inadequate treatment remains the same, i. e., 57.4 and 57 per cent; in females the inadequate treatment group represents 32.2 per cent and in the group without treatment 50 per cent. 3. The incubation period of clinical neurosyphilis is reduced approximately five years in a group of early inadequately treated patients as compared with a group receiving no treatment, i. e., from 19.2 to 13.1 years in males and from 14.9 to 8.7 years in females. 4. The incubation period of neurosyphilis is shorter in females than in males in both treated and untreated groups. The reason for this difference is not apparent from the study.

Pneumothorax Therapy in Lobar Pneumonia—Abernethy and his associates state that the introduction of large amounts of air into the pleural cavity with marked collapse of a pneumonic lung can be accomplished without serious harm to the patient. Although massive pneumothorax is necessary to effect relatively complete collapse of the consolidated lung, it frequently causes an increase in dyspnea, tachypnea and cyanosis. Pleural pain accompanying pneumonia is relieved after the introduction of a small amount of air into the pleural space, but larger amounts frequently induce substernal pain. Certain changes in the systolic blood pressure following massive artificial pneumothorax appear to be related to the elevation of the intrapleural pressure. Massive pneumothorax did not

favorably influence the course of pneumonia in six early cases. Decompression or withdrawal of air from the pleural cavity after subsidence of acute symptoms permitted reexpansion of the lung and did not cause reactivation of the infection.

Some Experimental Findings on Blood Pathology. M. Gerundo. Independence—p. 14.

Blood Clot Culture an Adjunct to Widal Test—Laybourn states that, because of the indefinite character of the early symptoms of typhoid, laboratory aids in diagnosis assume considerable importance. As a consequence, there is an unfortunate tendency to base the diagnosis solely on the Widal test (a test that is of no value until the disease is well advanced) to the exclusion of physical observations and histories. Both theory and practice have shown that the blood culture is the procedure of choice as an aid in the early diagnosis of typhoid. Of first importance is the fact that the typhoid bacillus can be isolated from the blood stream of practically all cases during the first few days of the illness—the time when the establishment of a definite diagnosis is of the most importance. The second point in favor of the blood culture is the fact that it gives more definite and conclusive evidence than is obtained from the Widal test, since the isolation and identification of the typhoid bacillus leave little room for doubt as to the cause of the illness. A third and most important point, so far as the prevention of the spread of typhoid is concerned, is the fact that typhoid bacilli can be isolated from the blood stream in mild and abortive cases of the disease, in which there might otherwise be little suspicion of a typhoid infection because of prompt recovery or atypical symptoms. Such cases are a greater menace to the health of a community than the clinically typical case. Both a blood and a stool specimen should be collected as early as possible in gastro-intestinal disturbances as an aid in the early diagnosis of both typhoid and bacillary dysentery.

Hemorrhagic Purpura with Intracranial Hemorrhage—Since 1926, Garvey and Stephens have made a diagnosis of hemorrhagic purpura in thirty cases. Of these, ten ended fatally, in seven of which the cause of death was an intracranial

hemorrhage and was confirmed in five at necropsy. It has been their experience and that of others that the most common cause of death in hemorrhagic purpura is the development of one or more large intracranial hemorrhages. The cases can usually be divided into three groups: (1) those characterized by the sudden development of focal signs usually those of a hemiplegia, (2) those with meningeal bleeding presenting the usual symptoms and signs of subarachnoid hemorrhage and (3) the group of coma and convulsions. A fourth group might be added to include cases presenting the syndrome of cerebellar apoplexy. The cause of death in two of the authors' patients was a cerebellar hemorrhage. While cerebral hemorrhage is one of the feared complications of hemorrhagic purpura it does not necessarily imply a fatal prognosis. Several instances of spontaneous recovery from subarachnoid bleeding have been recorded. The treatment of the intracranial complications of hemorrhagic purpura is not satisfactory. As a rule, there is little that can be done to avoid a fatal termination in the apoplectic type in which the patient develops sudden and profound symptoms of intracranial hemorrhage. When symptoms are less severe, with evidence of meningeal bleeding or minor focal signs, transfusion and splenectomy may be considered. In several of the present patients, previous transfusions did not prevent the occurrence of intracranial hemorrhage. Splenectomy was apparently an important factor in the recovery of one patient in whom intracranial bleeding had occurred. Splenectomy is attended by a definite risk and in most types of secondary purpura as well as in some cases of idiopathic hemorrhagic purpura it is not effective in controlling the hemorrhagic phenomena.

Carcinoma of Rectum—Herrmann asserts that proctoscopic examination is indicated for slight cancerous symptoms of the rectum. Only in this manner can early diagnosis of curable lesions be made. The earlier the diagnosis, the less complicated is the lesion, the higher the percentage of cures and the lower the mortality rate. A prolonged period of preoperative preparation is essential during which the colon is emptied, the fluid reservoirs of the body are filled and the glycogen reserve is improved. Peritoneal immunization can be accomplished by intraperitoneal vaccine. This offers protection against unforeseen accidents with fecal soiling of the peritoneum. Two cases are cited to prove the effectiveness of such local immunization. The operative procedure must be adapted to each case. An extensive abdominoperineal resection must be done in certain high lesions but it is inadvisable to apply this method to low rectal lesions that can be eradicated by posterior resection. The mortality rate rises with the technical difficulty of the operation. Destruction of inoperable or incurable rectal lesions by repeated electrocoagulation may replace palliative colostomy. Bowel action and consequent fecal soiling should be postponed as long as possible after the operation. This is accomplished by giving nothing by mouth for from two to four days while maintaining an adequate parenteral fluid intake. Morphine is indispensable. Early transfusion may be life saving, late transfusion is useless.

Enlargement of Accessory Sex Organs in Rats—In studying the effect produced by long periods of union McCahey and his collaborators united, by parabiosis, twelve pairs of young mature male albino rats. Litter mates of approximately similar weights were united, and for each pair another litter mate was kept for control. In four pairs of castrates and noncastrates united for periods of from sixteen to eighteen days there were no marked gross changes in the accessory sex organs as compared to the normal litter mates. In five pairs united for periods ranging from twenty-seven to 210 days the accessory sex organs of the noncastrates were enlarged. This increase in size affected the penis, the glands connected with the prepuce, the ejaculatory muscle, Cowper's glands, the three portions of the prostate, the seminal vesicles and the vasa efferentia. Enlargement was also noted in a glandlike structure which arises from the vas near its entrance into the posterior urethra. The period of 210 days of union represents approximately one sixth of the life cycle of the rat. The fact that the testes responded to stimulation for this prolonged period as shown by the increased size of the accessory sex organs at the end of the experiment does not lend support to the theory of antihormone formation. In the pair united for 210 days and also in another pair that was united for 190 days there were marked changes in the testes of the noncastrate. Pronounced changes in the spermatogenic epithelium and the interstitial cells were present. Cross sections showed the tubules packed with spermatozoa, and the layers of spermatogonia and spermatocytes were increased in number. Longitudinal sections of the tubules showed loss of the wave of spermatogenesis seen in normal sections, no areas free of completely formed spermatozoa were observed. The interstitial cells were increased in size and number. Histologic sections of the enlarged ventral lobe showed a marked increase in the size of the acini, which were also dilated to an abnormal extent with secretion. The epithelium was definitely hypertrophied. In some areas the connective tissue seemed increased in amount.

Fat Embolism H H Groszklos Philadelphia—p 175

Studies on Vitamin B Complex—Block and Hubbell fed rats a highly purified diet supplemented with 1 mg. of a vitamin B concentrate a day. More rapid and longer continued growth was observed when the antineuritic vitamin requirements were supplied by a concentrate prepared from rice polishings by alkali extraction of the material adsorbed on Lloyd's reagent than by the use of an equal number of units prepared by acid extraction. Thus, further evidence is presented that in addition to vitamin B₁ and B another factor (or factors) in the vitamin B complex is needed for the growth of the albino rat. This "third factor" is present in rice polishings. It is adsorbed on Lloyd's reagent and is eluted by dilute sodium hydroxide but not by alcoholic hydrochloric acid.

Treatment of Arthritis with Sulfur—Krestin used intramuscular injections of sulfur suspended in oil in the treatment of fifty cases of chronic nonspecific arthritis. The cases are classified according to the main anatomic changes determined by clinical and roentgen examination showing the extent of synovial peri-articular and para-articular tissue and cartilaginous and bony involvement. Since the results of treatment appear to depend very considerably on the extent to which bone and cartilage are affected, the cases are divided into four groups: 1. The bone involvement is slight or absent. 2. The bone changes are moderate and such as can be detected only in roentgenograms. 3. The bone changes are advanced and can be detected without roentgen examination. In many of these, partial dislocation of the joint and deformity are present. 4. The involvement is osteo-arthritis, frequently affecting the larger joints and spine of elderly individuals, the soft tissues show little or no involvement. Five patients refused to continue treatment after the first or second injection. It was found that, although no group is debarred from the prospects of some degree of recovery, the best results are to be expected in younger patients with relatively shorter histories and absence of advanced bony or cartilaginous damage. Improvement may be anticipated only in the soft tissues about the joints. When there is much wasting and contracture of the muscles the improvement will be less, and when deformity due to such changes combined with partial dislocation is present the chances of recovery become still less though pain and stiffness may be relieved. In about one fourth of the cases in which definite improvement occurred after treatment, symptoms subsequently returned. In these the relapsed condition was always less severe than that preceding treatment and in some it was quite mild. Simple therapeutic measures were generally sufficient to effect improvement. Recrudescence of symptoms occurred most often in groups 1 and 2 in which the patients were often younger and the disease had frequently been active and comparatively rapid in progress. In no instance was the disease made manifestly worse nor has any harmful effect been observed, provided a nonacute quiescent phase is chosen. Though induration and pain at the site of the injection sometimes occur, abscess formation has not been encountered. Treatment was not given during the acute phase of arthritis to elderly feeble or emaciated individuals to nervous hysterical or psychopathic patients to patients with active organic disease other than arthritis and to very obese patients. Improvement appeared to depend on the consistent occurrence of pyrexia and leukocytosis. The nature of such reactions is but little understood, but they seem to be associated with a general stimulation of metabolic processes and defense mechanisms.

Acute Free Perforation of Gallbladder—D. Abreu has observed free extravasation of bile three times in the last 116 cases of gallbladder disease encountered in his unit at operation or at postmortem examination (cases diagnosed as cholecystitis but not confirmed by operation have been excluded). Free perforation occurs most commonly in the elderly. Inflammatory disease of the gallbladder associated with calculi is

undoubtedly the cause of the condition. Although extensive gangrene of the wall associated with empyema has occurred in some cases, it is by no means always present. Age is a factor of great importance in the etiology of free perforation. A characteristic syndrome does not exist; few cases appear to have been diagnosed before laparotomy, acute cholecystitis, perforated gastric or duodenal ulcer, acute appendicitis, acute pancreatitis and intestinal obstruction have been simulated on several occasions. The safest guide to correct diagnosis lies in ceaseless vigilance when acute cholecystitis is being treated expectantly, especially in elderly patients, a rise of pulse rate associated with an increase in the area of abdominal tenderness must not be neglected. When uncertainty exists about the condition of a patient being treated expectantly for acute cholecystitis, laparotomy is desirable. Perforation can occur in a patient confined strictly to bed and on a fluid diet, as in one of the reported cases.

Surgical Treatment of Aneurysms—Romanis states that the aneurysms essentially suitable for surgery are those of the neck and limbs. The nearer the trunk the aneurysm is, the more difficult and delicate is its operative treatment. The cases described have all been treated by open operation, though certain aneurysms can be benefited by such other procedures as compression, needling, electrolysis and general medical measures. If it can be performed, the formal operation of excision of the sac with ligation of all branches entering it, as close to the sac as possible, and noninterference with the accompanying vein is the operation of choice. If it is impossible, a cure is often obtained by one of the other surgical procedures, the most promising being ligation of the main vessel immediately above the sac. Most of the so-called peripheral aneurysms occur in the flexures of the limbs, either in the popliteal space, Scarpa's triangle or the axilla. Many are associated with injuries. They are far more common in men than in women, but when seen in women they are usually associated with a positive Wassermann reaction, whereas this is by no means always the case in men. Certain aneurysms of this kind are, or in the past have been, associated with certain trades, such as the popliteal aneurysm seen in postboys and femoral aneurysm seen in butchers as a result of stabs in the thigh from their knives while sharpening them. Others are seen as a direct or indirect result of surgical procedures. The cases described are representative of arteriovenous aneurysms of the cavernous sinus of aneurysms of the carotid, internal iliac, innominate, femoral and popliteal arteries, of femoral arteriovenous aneurysms and of other aneurysms of the limbs.

Artificial Pneumothorax for Relief of Pleural Pain—Shaw believes that the pain of acute dry pleurisy demands removal in young patients on humane grounds. In the elderly this is imperative as a prophylactic measure against the occurrence of anoxemia and atelectatic pneumonia, which is so often fatal. The therapeutic methods in general use are only partially effective or dangerous. The induction of a shallow pneumothorax invariably relieves pleural pain and so removes anoxemia and atelectasis. The amount of injected air necessary is so small as to be quite harmless. Two cases are cited in which atelectatic pneumonia and anoxemia, secondary to pleural pain, suggested a fatal prognosis. Dramatic recovery followed the induction of an analgesic pneumothorax. In post-operative cases in which an abdominally initiated diaphragmatic paralysis enhances pulmonary basal atelectasis, the value of pneumothorax seems worthy of further research.

Roentgen Therapy of Exophthalmic Goiter—Gunsett and his co workers report the late results of roentgen treatment of 100 patients with exophthalmic goiter. All but seventeen had received treatment more than five years before the follow up, and these seventeen had been at least three years under observation. Forty-four appeared personally for check up and the others were reached by writing. Of the forty-four who appeared thirty-two, or 72.7 per cent, were in excellent health; eight had only slight disturbances, three results were considered unsuccessful and one patient was operated on six months after the roentgen treatments. Forty-two of the fifty-six who wrote in were in excellent health, ten were not improved and four said that they were improved though not completely recovered. The authors believe that these results justify the use of roentgen rays in the treatment of exophthalmic goiter.

- *Necessary Conditions Results and Technique of Arterectomy in Arterial Obliterations R Leriche and R Fontaine—p 1953
Sinocarotid and Cardio-Aortic Vasosensitive Zones in Determination of Sudden Death A Salmon—p 1956

Arterectomy in Arterial Obliterations—Leriche and Fontaine state that they have performed eighty arterectomies between January 1925 and May 1935. Nine were humoral, one cubital, three external iliac, sixty superficial femoral, five popliteal and two posterior tibial. They feel that, when the operation is performed for arterial occlusion, the artery, although having ceased to act as a vascular tube, continues to act as a vasoconstrictor nerve. This view has been confirmed both clinically and experimentally. It is necessary technically that the arterectomy should extend beyond the obliterated region both above and below. The operation is, however, inadvisable unless the obliteration is complete. Both above and below the arterial resection must respect the first permeable collateral vessel leaving it intact. The results in thirty-four cases of Buerger's disease were divided into five unknown, ten failures, seven temporary improvements, eight good results and four of less than a year's duration. The thirty-four operations performed for arteriosclerotic obliterations were divided into one death (by gas gangrene), five unknown, two failures, eight temporary improvements and eighteen good results, six of these being observed for longer than a year. Finally, the authors state that it is wise to close the operation with care as to hemostasis. Bleeding of the muscular arterioles is frequently seen almost immediately after the procedure is done. The vasodilatation is always rapid.

Calcium in Diet and Experimental Hypoparathyroidism—Cazzamali carried on experiments in thyroparathyroidectomized rats with the aim of ascertaining the influence the calcium content in the diet may have on experimental hypoparathyroidism. The animals in three different lots were given one of three different diets: diets almost deprived of calcium or with normal or increased calcium. The author concludes

that a hypocalcic diet increases the demineralizing action of thyroparathyroidectomy. The weight of the ashes of bones, viscera and soft parts of the organism of the animals which is lower in thyroparathyroidectomized than in normal rats is still lower in those which are given the hypocalcic diet. A diet with either a normal or higher than normal calcium content cannot control the progress of the demineralization caused by thyroparathyroidectomy, but it controls the clinical symptoms that follow it. The administration of the hypocalcic diet results in death of the animals, which rapidly develop cachexia and asthenia and die in tetany shortly in the evolution of the experiments. The administration of a diet with calcium content, either normal or increased, enables the animals to survive the operation. In these cases the manifestations of hypoparathyroidism which ordinarily follow thyroparathyroidectomy tetany included, do not make their appearance. The animal's life after the operation is almost normal except for a partial limitation of the somatic development which is probably due to the suppression of the thyroidal function.

*Influence of Artificial Pneumothorax on Electrocardiograms I Natin—p 2002
Syphilitic Gumma of Tongue Case A Bigatti—p 2026

Index of Excursion of Uterus—Jürgens calls "index of excursion of the uterus" the distance in centimeters that the uterus held by forceps, can be displaced upward and downward from its normal location by means of light pushing and pulling movements. The normal index of excursion of the uterus is 4 cm (2 cm upward and 2 cm downward) in nulliparas and from 6 to 8 cm in women who have borne one or more children. In the last group of patients an index of 10 or 12 cm is found before appearance of prolapse of the uterus. In these cases the downward excursion is larger than the upward one. The existence of an index of excursion greater than 6 or 8 cm is of diagnostic value in latent or potential prolapse, by which the author means the relaxation of the muscles that support the internal genital organs and of the perineum a condition that precedes the onset and evolution of prolapse of the uterus. Latent prolapse is characterized by the disproportion between the intensity of the local and general symptoms on the one hand and the almost unnoticeable anatomic changes of the internal genitalia on the other. The symptoms of the condition are a sensation of relaxation of both the supportive and the perineal muscles a downward sensation of the genitalia disturbances of the gallbladder, lumbar pains and aching of the legs which become worse with physical exercise and are lessened with rest. The general symptoms consist of gastric and intestinal disturbances, headache nervousness and sometimes psychasthenia. The treatment of latent prolapse as well as of prolapse in evolution, consists in the performance of a corrective operation. The temporary use of pessaries is indicated, however as a preliminary treatment before an operation in certain cases such as in young married women and in women who refuse to be operated on. An advantage of the temporary use of pessaries is that incontinence of urine, which frequently complicates prolapse is made evident by the temporary reduction of the prolapse and can be corrected during the same operation.

Influence of Pneumothorax in Electrocardiogram—Natin made studies of the variations of the electrical axis of the heart in the electrocardiogram before and after artificial pneumothorax in thirty-two cases. He concludes that pneumothorax of the right side causes a shifting to the right of the electrical axis of the heart and horizontalization of the organ. The pneumothorax on the left side causes a shifting to the left of the electrical axis of the heart and verticalization of the organ. Parietal and diaphragmatic adhesions, when present,

maintain the heart and the hemidiaphragm in their position, thus preventing the appearance of changes of the heart and of its electrical axis in the electrocardiogram. The presence of an effusion on the right side of the thorax may cause an accentuation of the shifting of the electrical axis of the heart to the right in right pneumothorax and a neutralization of the shifting to the left and even appearance of the shifting to the right in left pneumothorax. If the heart takes the horizontal position as a result of the pneumothorax, its electrical axis shifts to the right, if it takes the vertical position its electrical axis shifts to the left. This fact was proved by the electrocardiograms obtained during discontinuation of pneumothorax. Slight changes of the heart do not make their appearance in the electrocardiograms or appear only when the electrocardiogram is taken in certain positions. Air insufflations may act either as the determining factors in the onset of extrasystoles or control them, probably by a mechanism of vagal stimulation. In reviewing the literature on the subject one finds that the opinions are conflicting. Some authors claim that the electrical axis of the heart shifts to the right in all cases of pneumothorax, while others believe that it does not change and still others state that its variations are irregular. Some authors report the observation of slight changes in the electrocardiogram after artificial pneumothorax, while others failed to find them. Natus's observations confirm those previously reported by Naunin and point out the erroneousness of the classic conceptions on the relation between the position of the heart and the direction of the shifting of the electrical axis of the heart in the electrocardiogram.

*Severe Burns with Phosphorus and Treatment W Starz—p 47

Vitamin D Sclerosis in Human Subjects W Gerlach—p 49

Congenital Amputations H F O Haberland—p 55

Methods of Artificial Respiration—In evaluating the methods of resuscitation, Bruns disregards those which employ machines and gives his attention only to the manual methods. He says that Silvester's method of artificial respiration is the best, because it introduces most air into the lungs and also effects a movement of the blood from the right to the left side of the heart. If a second person is available, the author suggests that this person, while sitting on the thighs of the unconscious person, perform cardiac massage according to the method of Maass-König, while the person performing the artificial respiration presses during the period of expiration the upper arms and the elbows of the unconscious person laterally against the thorax, instead of crossing them over the sternum. In the cardiac massage according to Maass-König, the thenar eminence of the open right hand is pressed in rapid succession into the region of the heart, approximately between the region of the apical beat of the heart and the left side of the sternum. The thrusts should be about 100 per minute. This rate eliminates the danger of exerting too great a pressure.

Treatment of Burns Caused by Phosphorus—After reporting the case of a man who sustained severe burns on the hands while breaking a bottle that contained phosphorus diluted in carbon disulfide, Starz points out that since phosphorus is used in gas warfare in the form of phosphorus fire bombs, the treatment of such injuries deserves attention. He shows that burns produced by phosphorus involve two destructive processes: the one is the direct action of the flames and the second is the corrosion of the tissues by the acid that is formed. In the treatment of phosphorus burns it is most important to put the injured part as soon as possible into a 5 per cent solution of sodium bicarbonate of approximately body temperature. However, this submersion should not be continuous, but the injured part should be lifted out from time to time so that the air can reach the lesion. This exposure to air facilitates the oxidation of the particles of phosphorus still adhering to the tissues. The solution of sodium bicarbonate on the other hand, makes possible the neutralization of the newly forming acid and thus reduces the pain. The dipping into the solution and

the exposure to air must be continued until the development of vapors of phosphorus pentoxide ceases and there is no longer a garlicky odor, phosphorescence or severe pain. After this has been accomplished, the customary treatment for burns is applied.

Magnet Operations V I Alekseeva—p 624

Partial Transverse Transplantation of Corneal Layer M A Shterenberg—p 637

Pathogenesis of Eye Symptoms in Exophthalmic Goiter—According to Spector, the ocular symptoms in exophthalmic goiter do not depend directly on the thyroid. The cause of both the enlargement of the thyroid and the ocular symptoms is a lesion of the diencephalic-hypophyseal system. The mechanism of the production of the symptoms is an increase in the tone of the corresponding muscles. Exophthalmos is the result of increased tonus of the oblique muscles of the eyeball caused by a lesion of the extensor center. The eyeball is pulled out rather than pushed out. Symptoms characteristic of exophthalmos resulting from retro ocular tumors, such as vascular changes and changes in refraction, are absent here. On the other hand there is present a tenderness at the point of attachment of the oblique muscles. The Mobius sign is due to the increased tone of the oblique muscles increasing the diverging position of the eyeball. Lid symptoms, the Dalrymple, von Graefe and Stelwag signs, are due to the increased tone of the superior levator muscle of the lid. The Joffroy sign depends on the increased tone of the frontal muscle. The author regards all these muscles as the upper half of muscles of facial expression the cellular elements of which are located in the floor of the third ventricle. These cell groups and the extensor center are under the toxic control of the hypophyseal and thyroid secretions. The effect of the thyrotropic hormone of the anterior portion of the pituitary is to cause enlargement of the thyroid. A vicious circle is thus formed, a lesion of any part of which may cause exophthalmic goiter. Rapidly developing eye symptoms in exophthalmic goiter point to a primary lesion of the brain centers and slowly developing symptoms to their depression. Improvement in eye symptoms after thyroidectomy can take place in slowly developing symptoms. In fulminant exophthalmic goiter, thyroidectomy does not bring about any improvement of the exophthalmos. Positive results can be obtained only through sectioning of the oblique muscles. Bilateral limitation of fields of vision following thyroidectomy is explained by a compensatory enlargement of the hypophysis. The latter apparently plays an important part in the etiology of exophthalmic goiter.

RESUSCITATION OF THE NEW-BORN

JOHN F McGRATH MD
AND
KATHERINE KUDER, MD
NEW YORK

This study was prompted by the belief that many new-born babies are lost because of lack of proper treatment of asphyxia neonatorum. There has been little determined or concentrated effort to improve the method of accomplishment of normal breathing in its practical and universal application. In many maternity institutions there is still no standardized treatment or teaching of the modern conception of the theory and practice of resuscitation. Even modern textbooks on obstetrics continue to devote space and pictures to demonstrate methods of treatment that are no longer tenable. The names Byrd, Dew, Schmitze, Silvester, Laborde and Prochownik belong, properly, to historical medicine.

ASPHYXIA NEONATORUM

The frequency of asphyxial fetal mortality is, indeed, difficult of estimation. Cruikshank¹ reports, after a very exhaustive investigation of postmortem examinations of 800 cases of neonatal deaths, that 68 per cent of these were due to asphyxia neonatorum and "allied conditions." In this study an attempt is made to evaluate with some degree of accuracy the incidence of the varying factors often causative, sometimes resultant and frequently only coincident. Birth injury, prematurity and developmental defects are often most difficult in their proper allocation. In contrast also with Cruikshank's study we define the neonatal period as fourteen rather than twenty-eight days. It is obvious that accurate inference is not always possible. In this analysis of 216 fetal deaths, eighty-seven of which were neonatal autopsies showed an incidence of pathologic respiratory conditions in 17.59 per cent. Atelectasis was present in twenty-two of these eighty-seven cases, an incidence of 25.28 per cent. Henderson² says that still-born and new-born deaths due to respiratory complications amount to four in 100.

Asphyxia neonatorum is as descriptive a designation of what occurs when a new-born child does not breathe properly as any that might be used. It is well understood that this condition is due to insufficient aeration or, more properly, insufficient oxygenation of the fetal blood. As Vandell Henderson has pointed out, the normal baby starts to breathe under essentially the same stimulus that causes an adult to breathe again after

holding the breath.³ The fetus does not breathe in utero because the proper equilibrium of its blood chemistry is maintained by the placental circulation. Fetal blood is too well arterialized to stimulate the fetal neurorespiratory center, which is difficult to excite while the lungs are atelectatic. Occasionally respiratory effort before birth may cause aspiration of a small amount of amniotic fluid which probably inhibits further respiratory effort and is readily absorbed in the alveoli.

Undoubtedly many reactions and reflexes play a part in the excitation of the neurorespiratory system, the most evident probably, is contact of air with the fetal skin and the mucous membrane of the airways. Other impulses, such as temperature, heat and cold gases or liquids, skin irritation, sprinkling posture or pain that is to say any of the various known peripheral stimuli, may initiate respiratory activity in the new-born.

At any rate, stimulation of the babies' skin and air passages by air normally activates the Hering-Breuer reflex, which determines inspiration and expiration. Oxygen determines the sensitivity of the neurorespiratory system to its specific stimulus, which is carbon dioxide. Extreme deficiency of oxygen in the fetal circulation paralyzes the system, according to Henderson. Oxygen may increase or disappear while carbon dioxide may also decrease. That there is a great increase in carbon dioxide, as has been supposed, probably is not often the case. The beneficial absorption of carbon dioxide disproves the conception of asphyxia as an acidosis. But that the change of chemical balance exerts a profound influence on the vital centers there can be no doubt. Obviously, the more profound the depression of the sensitivity of these centers, the stronger the stimulus required to excite respiratory activity, as seen when carbon dioxide from 20 to 30 per cent is used.

While there still exist doubt and controversy concerning the chemical nature of the blood in the normal and in the asphyxiated baby and the interchange of gases in normal lung ventilation, pending revision and confirmation of this physiologic activity, the contention of Henderson that the beneficial results of carbon dioxide administration demand its more universal usage in asphyxia should be urged. The insistence of Eastman,⁴ Kane and Kreiselman⁵ and others that the administration of carbon dioxide increases the "acidosis" of the asphyxiated cannot be reconciled with the clinical phenomena observed by so many.

Henderson describes three types of asphyxia, the apneic, the acarbic and the chronic. The apneic represents an intensive but brief deficiency of oxygen, the acarbic is characterized by a marked reduction of the blood alkali reserve secondary to insufficient carbon

dioxide stimulus and may show an acid excess, the chronic defines the condition when the respiratory center is depressed by a chronic lack of oxygen.

It might be of value in bringing this problem properly to the attention of the medical profession to emphasize, as Alan Moncrieff⁵ has done, that a large part of neonatal deaths during the first month of life might well justify the suggestion that the word "suffocation" is a fairer one. The terms "asphyxia" and "atelectasis" camouflage, rather than define, the true significance of fetal failure to breathe. That the respiratory failure at birth and at a later period of life is essentially the same, both in mechanism of production and treatment, there can no longer be any doubt. When a new-born baby does not breathe normally, it is fair to assume that one of two causes is present. Either there is a central anomaly, such as (1) immaturity, (2) intracranial injury or pressure, (3) chemical depression, due to narcotics, oxygen lack or carbon dioxide excess, secondary to improper arterialization of the center—as found in any circulatory or cord obstruction—or else there is a peripheral abnormality, such as immaturity

Another obstructive factor that needs consideration is the intrinsic adhesion of the alveoli in the solid fetal lungs before birth and the natural cohesive state of the bronchioles and bronchi. Coryllos⁷ has estimated that the resistance offered by these factors in the dog is equivalent to 14 cm. of water pressure. This resistance, or obstruction to the entrance of air, will vary, of course, with the type of baby, a weakly premature infant will present more resistance than a husky, well developed child. Flaccid atonic structures in the pharynx and larynx may offer obstruction to the free passage of air. Coryllos and Birnbaum⁸ have confirmed Keith's⁹ impression that the infant lung expands by "opening like a lady's fan" and have found that the effort to maintain normal ventilation of the lung is not as great as that required to initiate expansion. The force required to maintain adequate expansion and normal breath excursions is estimated at from 8 to 10 cm. of water. It is probably true that the forced expiratory effort, as when the baby cries, against a partially closed epiglottis contributes in a large measure to complete dilatation of the alveoli.

It is our belief that a maximum pressure of 25 mm. of mercury can be used with safety in infant resuscitation. The resistance and capacity of the chest walls make the likelihood of overdistention of alveoli very remote. The lack of evident lung trauma in our cases that came to autopsy seems to indicate that more complete expansion and greater pressure would enhance the success in the treatment of asphyxia of the new-born.

DIAGNOSIS OF ASPHYXIA

At birth, the diagnosis of asphyxia is quickly made by failure to observe any attempts at respiration or to note very feeble ones. Pulsation of the cord is usually present, but not necessarily, though the apex beat may be visible. Whether the baby is cyanotic ("livida") or white ("pallida") makes little or no difference. The condition is the same, although, generally speaking, the "white asphyxia" baby presents a more serious problem. Recognition of the fact that the two types may be the result of the same cause makes it obvious that the treatment will be essentially the same. The presence of mucus in the mouth, nose and pharynx may be easily evident. There may or may not be signs of attempted breathing, from an occasional weak gasp to a convulsive inspiratory spasm. Change in color may be seen, blue to white and even occasionally white to blue. Percussion and auscultation of the chest are of questionable value, except in cases in which incomplete expansion may persist over many days, and may even show in an early roentgen examination. Persistent impaired breathing may show the physical signs of pneumonic consolidation. Judging from the frequency with which we find partial atelectasis in neonatal lungs at autopsy, complete expansion of the lungs is a slow progressive process, taking many days, even in normal babies, as Wasson¹⁰ has shown.

Occasionally at birth the baby gives one cry and then immediately stops any further attempt at breathing. This condition is found especially in premature birth and is followed by fetal death unless vigorous resuscitation is instituted at once. When breathing begins

of the lung alveoli, developmental deficiency, circulatory failure, or the more common condition of obstruction somewhere in the air passages, which means delayed expansion of the lungs with the attendant improper ventilation.

In those cases of failure due to reasons of central origin, the history and clinical picture are fairly obvious, as, for instance, prematurity, prolonged labor, difficult or instrumental delivery, narcotics, prolapsed cord or congenital heart disease. In this class many babies may be saved.

But it is in the second group, failure due to obstruction in the upper respiratory passages, with which we are most concerned, for herein we believe lies the greatest opportunity to lessen the incidence of neonatal death. The frequency of obstructive material, mucus, amniotic fluid, meconium, vernix caseosa or epithelial debris is evident to every obstetrician and is almost always found in careful microscopic study of infant lungs at autopsy, as in the report of Farber and Sweet,⁶ in which 88 per cent of 124 unselected babies dying within the first five weeks of life showed aspirated material in the bronchioles and alveoli.

after treatment it is rapid and shallow, followed by intermittent weak attempts to cry, but the irregularity of its rhythm is characteristic

PROPHYLAXIS OF ASPHYXIA

Admittedly asphyxia neonatorum is often unexpected and unpreventable. Improved obstetric care, however, will lessen the incidence of fetal suffocation. Proper antepartum and intrapartum treatment can eliminate many of the causative factors. The increased and indiscriminate use of medication for the induction or relief of labor undoubtedly contributes not a little to fetal morbidity and even mortality. Operative delivery may either cause or prevent asphyxia, it may be well indicated for the relief of fetal distress or it may be the reason for such distress.

There can be no doubt that prolonged labor, particularly when the membranes rupture early, increases the likelihood of asphyxia. Toxemia, difficult labor, instrumentation, the use of posterior pituitary extract or quinine, the frequent exhibition of sedatives, either narcotic as with opium and its derivatives or depressant as with barbiturates or allied drugs, all tend definitely to increase the incidence of asphyxia. Occasionally cord anomalies, such as knots or prolapse, or premature separation of the placenta, indicate special etiology in individual cases.

The prevention of asphyxia must include the judicious consideration of all these factors. We have analyzed 226 cases of resuscitation that occurred in the obstetric service of the New York Hospital from March 1, 1933, to Dec 31, 1934. Of 4,865 consecutive births, 226, or 4.64 per cent, required some measure of resuscitation. During this period the fetal mortality was 216, or 4.4 per cent. Of those who died, thirty-seven, or 17.1 per cent, received resuscitation treatment. It is evident that the problem of infant resuscitation is a matter of concern and a necessary attribute to the reduction of infant mortality. In an attempt to evaluate and correlate the factors concerned in asphyxia neonatorum and its prevention and cure a careful analysis has been made.

FULL TERM SPONTANEOUS DELIVERY

Of the total number, 3,651, of babies born at full term by spontaneous delivery, only ninety, or 2.465 per cent, required resuscitation. In this group of ninety there were six fetal deaths, an incidence of 6.33 per cent.

Primigravidas numbered fifty with four infantile deaths, while there were forty multiparas with two infantile deaths.

Normal pelvis were present in seventy of these ninety cases though there were five infantile deaths. Eight generally contracted pelvis showed one infantile death. Other types of abnormal pelvis showed twelve infants needing resuscitation, with no infantile deaths.

Left occipito-anterior presentations occurred in forty-four cases in which resuscitation was needed, with four infantile deaths. Thirty-one cases of right occipito-anterior presentations gave an infant mortality of 1. In three cases of left occipitotransverse presentation, one baby died.

Among the complications of pregnancy, two cases of intrapartum infection showed an incidence of two infant deaths, while toxemia of pregnancy (seven infants requiring resuscitation) showed an infant mortality of 1. The cord was about the neck in twenty-one cases requiring resuscitation with an infant mortality of 3.

In four babies requiring resuscitation, though they weighed less than 2,500 Gm there was no fetal death. In twelve weighing from 2,500 to 3,000 Gm there was one infant death. Sixty-four babies weighing from 3,000 to 4,000 Gm showed a mortality of 4 while in ten cases of infant weight of more than 4,000 Gm there was one death.

In all but five cases of the ninety deliveries, some form of anesthesia and analgesia was recorded. In the six infantile deaths, anesthesia was administered in all, and morphine also in two.

The membranes ruptured spontaneously in seventy-three of these ninety cases with six infantile deaths, while artificial rupture in seventeen was attended by no infantile death. Four babies died in sixty cases in which rupture of the membranes was known to have been not more than nine hours before birth.

In seventy-five deliveries in which the first stage was less than twenty hours, four babies died, with two

TABLE 2—Infantile Deaths in Ninety Full Term Spontaneous Deliveries

Case	Weight Gm	Condition at Birth	Methods of Treatment	Autopsy
1	3,450	No cry at birth	moderate mechanical stimulation	intratracheal technique
		medicinal	repeated in nur cry	inter died at 32 hours
		Autopsy	Bilateral tear of the tentorium cerebelli	lateral cranial hemorrhage
2	3,640	Breathed poorly no cry	repeated mechanical stimulation	intratracheal technique
		medicinal	carbon dioxide oxygen by mask in nur cry	given 20 cc of whole blood died at 24 hours
		Autopsy	Tear in falx cerebri	subdural hemorrhage
			bilateral bronchopneumonia	
3	2,620	No reflexes present at birth	liver large had mechanical stimulation	intratracheal technique
		medicinal	died at 1 hour	
		Autopsy	Partial atelectasis	extradural hemorrhage of cord pleural and pericardial effusion ascites
4	4,400	Cyanotic at birth	had mechanical stimulation	intratracheal technique
		died at 2 hours		
		Autopsy	Meconium in bronchioles	erythroblastosis
			eczema	mosis and petechial hemorrhages
5	3,150	Scalp face and lips cyanotic	prolonged intratracheal technique	stillborn
		Autopsy	Partial atelectasis	
6	5,400	Never breathed heart beat one minute	mechanical stimulation	medicinal intratracheal technique
		for twenty minutes	stillborn	
		Autopsy	Bilateral atelectasis	

deaths in fifteen cases in which the first stage lasted from twenty to fifty hours or over. One infant death occurred among twenty-six deliveries in which the second stage lasted from one to twenty-nine minutes, while five infants died in twenty-seven cases in which the second stages lasted from sixty to ninety minutes or more.

A brief summary of the six infantile deaths and autopsy are recorded in table 2.

OPERATIVE DELIVERY AT FULL TERM

Resuscitation therapy was done in 115 instances out of 1,064 operative deliveries at full term, an incidence of 10.8 per cent. Of these 115 cases the infant deaths numbered eighteen or 15.6 per cent.

Eight babies died in the delivery of sixty-seven primiparous mothers in whom resuscitation therapy was instituted. Of forty-seven babies born to multiparous mothers, ten babies died.

In seventy-five cases in which the pelvis was normal, eleven babies died, while in seventeen cases presenting generally contracted pelvis, two babies died. Ten cases of generally contracted pelvis showed an infant mortality of three.

Five babies died in thirty-six cases of left occipito-anterior presentation, four in eighteen cases of right occipitoposterior and three in twenty-one cases of breech presentation.

The greatest incidence of infantile deaths in the operative group were those of toxemia of pregnancy, in which four babies died in nine cases of toxemia.

TABLE 3—*Infantile Deaths in One Hundred and Fifteen Full Term Operative Deliveries*

Case	Weight Gm	Condition at Birth	Methods of Treatment	Autopsy
1	4040	Low forceps heart irregular did not breathe cyanotic convulsions vomited blood	vigorous mechanical intra tracheal technic for twenty minutes mask (carbon dioxide oxygen) 20 cc of whole blood given died 14th day	Autopsy Bilateral lobar pneumonia bacteremia ruptured brachial plexus
2	3500	Midforceps markedly asphyxiated mechanical intra tracheal technic for two hours edema of larynx from trauma causing obstruction given 10 cc of whole blood died at 36 hours		Autopsy Wide tentorial tear partial atelectasis aspirated amniotic fluid
3	3000	High forceps did not breathe for one and one half hours all methods of resuscitation used slow breathing began elomic contractions transfusion of 50 cc of citrated blood died at 36 hours		Autopsy Fracture of left clavicle hemorrhage under capsule of thymus
4	3490	Low forceps intratracheal technic Infant deadborn (fetal heart lost just prior to birth)		Autopsy Hemorrhage in falx cerebri and tentorium cerebelli
5	3900	Bag induction version extraction gasped once before complete delivery fetal heart 40 per minute placenta praevia intratracheal technic stillborn		Autopsy Petechial hemorrhages of scalp
6	4850	Breech extraction heart 60 per minute intratracheal technic for ten minutes stillborn		Autopsy Bilateral atelectasis
7	3910	Midforceps intratracheal technic deadborn		Autopsy Atelectasis rupture tentorium cerebelli bilateral
8	2850	Low forceps cyanotic all methods of resuscitation used deadborn		Autopsy None
9	3410	Breech extraction with forceps to aftercoming head cyanotic intratracheal technic deadborn		Autopsy Tentorial tears hemorrhage into cerebellum and left cerebrum
10	3900	Midforceps gasped twice only shoulders difficult to deliver intratracheal technic for fifteen minutes Infant died in 15 minutes		Autopsy None
11	3580	Midforceps intratracheal technic no response deadborn		Autopsy None
12	4230	Low forceps intratracheal technic and intracardial atropine deadborn		Autopsy Hemorrhage into brain and cord bilateral hydrothorax no left umbilical artery
13	3400	Classic cesarean section no cry cyanotic mechanical intratracheal technic one hour before spontaneous respiration larynx and trachea mildly traumatized died first day		Autopsy Pericarditis pleural and pericardial effusion
14	2900	Breech extraction cyanotic weak cry mechanical suction oxygen by funnel died at 3 hours		Autopsy Congenital atelectasis partial absence of kidney
15	4260	Low forceps heart 40 per minute heart lost five minutes after birth intratracheal technic stillborn		Autopsy Post term stillborn fetus
16	2770	Midforceps sixteen hours after delivery resuscitated by intratracheal technic died at 23½ hours		Autopsy Tear of left tentorium cerebelli hemorrhage into falx cerebri
17	2850	High forceps limp no respirations intratracheal technic for one hour 20 cc of whole blood given died in 10 hours		Autopsy Subdural hemorrhage in brain and cord
18	3640	Midforceps heart heard intratracheal technic alaphlobin stillborn		Autopsy Bilateral tentorial tear subdural hemorrhage

In fourteen cases of cord about the neck, the infant mortality was five. The cord was knotted in one case and prolapsed in four cases without mortality.

Infant weight showed a mortality of six in the group from 3,500 to 4,000 Gm, compared with four in the other groups.

In eighty cases of spontaneous rupture of the membranes there were twelve infantile deaths, while in thirty-five artificially ruptured there were six deaths.

As for anesthesia in thirty-one deliveries, seven babies died when gas and oxygen were administered. Five died when gas, oxygen, ether and some analgesic such as morphine, scopolamine or the barbiturates were administered to thirty-nine mothers.

Three infantile deaths occurred in twenty-seven cases in which the first stage of labor was from one to nine hours and seven in thirty-five cases in which the first stage was from ten to nineteen hours. In eight cases in which labor in the first stage was from forty to forty-nine hours, one baby died. There were eight infantile deaths in forty-one cases in which the second stage was from one to fifty-nine minutes and two deaths in eighteen deliveries in which the second stage lasted 150 minutes or more.

In fourteen cases of breech extraction the infant mortality was two. In thirty-nine cases of low forceps extraction the infant mortality was five. In thirty cases of midforceps extraction the infant mortality was six, and in four cases of high forceps application there were no infant deaths. In eight cesarean sections one baby was lost. Version in five cases was attended by one infant death.

A brief recording of the eighteen deaths in 115 operative deliveries is given in table 3.

PREMATURE DELIVERY

Twenty-one premature babies were delivered in whom resuscitation was done. Thirteen of these died. Three were of seven primigravidas and ten of eleven multiparas. Eight of these babies weighed 1,500 Gm or less, and five weighed from 1,500 to 2,000 Gm. A brief summary of the thirteen infantile deaths is given in table 4.

TREATMENT OF ASPHYXIA

The actual treatment of asphyxia is based on three fundamental concepts. First, open airways. That is, all obstruction must be removed, mucus, amniotic, meconium or other fluid must be removed by aspiration. Second, insufflation or distention of lung alveoli, which must be brought about. Third, stimulation of the neurorespiratory center with carbon dioxide after its sensitivity has been increased with oxygen.

It is fitting to recall that John Hunter in 1776 used a double chambered bellows, one for suction and the other for filling the lungs, according to Arthur Keith. Monro Secundus passed a catheter into the larynx by way of the mouth. Meltzer¹¹ and Auer in 1910 introduced the method of intratracheal insufflation, though pharyngeal insufflation was deemed more practical.

In case of long labor, toxemia, prematurity or necrosis or in any case in which fetal distress is diagnosed, preparations for infant resuscitation are imperative. When possible, the first step is the administration of oxygen and carbon dioxide to the mother early in the progress of her labor. At birth the gentle handling of the baby without haste is essential. Holding the baby by the feet with the head low in the air and gentle stroking of the throat toward the mouth will cause the expression of mucus or other fluid and make aspiration less likely. During this time inspection will show the fetal heart impulse and rate. Mild patting of the soles of the feet or placing a gauze-enveloped little finger in the mouth and pharynx in an attempt to remove mucus is occasionally attended by the onset of respiratory effort.

It is well to reiterate that undue haste is harmful. The apical beat and heart action require constant careful

11 Meltzer S. J. M. Rec. 92:110 (July 7) 1917.

observation There need be no alarm while pulsation is regular and strong A feeble, intermittent and slow cardiac activity is cause for uneasiness That irritation of the peripheral nerves, the cutaneous reflexes, as in moderate intelligent patting of the buttocks or soles of the feet, the occasional dorsal slit and retraction of the prepuce, or any pain stimulus is often the initiating excitant of respiratory effort is well understood Likewise, it is well known that overactive handling and employment of methods of artificial respiration are often traumatic to the point of fatality The postmortem finding of visceral hemorrhage is a matter of frequent record

Mention must be made of medicinal treatment of asphyxia neonatorum Lobeline has been used by us with rather indifferent results It is undoubtedly a definite respiratory stimulant, but according to Henderson, Moncrieff, Curtis and Wright¹² and others it is also a cardiac depressant It has been used in our series usually when all other efforts have failed, and in no instance have we ascribed success to its use

Coramine (pyridine-beta-carboxylic acid diethylamide) and icoril (meta-oxy-n-ethyl-diethyl aminomethylaminobenzol-chlorhydrate + meta-oxyphenyl propanolamine-chlorhydrate) have not been used in this series They, too, are stimulants of the respiratory center with perhaps less depressant action but may induce varying degrees of excitation from restlessness to twitchings or even convulsions Needless to say no drug therapy provides the fundamental clearance and patency of the air passages

While methods of artificial respiration are of some value and should be employed under emergency conditions, it is necessary to emphasize their inefficiency and to stress their danger Even mouth to mouth breathing may inflict serious injury, as in the fatal case reported by Emmert¹³ and referred to by Moncrieff Methods of forced or positive pressure insufflation with mask and pump are unsound in theory and unsafe in fact It must be remembered that one is dealing with the baby who is not breathing In the use of the many ingenious machines conceived for automatic and continuous insufflation, rhythmic alternation of positive and negative pressure, one must not lose sight of their limitations and liabilities

Apparatus of the types exemplified by Drinker¹⁴ Kreiselman, Von Wachenfelt and Mollison,¹⁵ or the more modern pulmotor called a resuscitator, are useful for prolonged passive respiration, particularly when insufflation of carbon dioxide and oxygen is incorporated as an essential feature of such instrumentation Mechanically controlled respiration is not precise, even in expert hands The rate, rhythm and depth of expiration and inspiration of a new-born baby are most variable Usually it is not possible to synchronize those factors or to determine just how a baby should breathe The rate and rhythm are determined by the need of the individual The blood chemistry exacts its own requirement and overregulation or underregulation of artificial respiration may well inhibit or impair this function There is bound to be more or less leakage around a mask Overdistention of the lungs and inflation of the stomach are obvious probabilities, but the

outstanding objection to such mechanical respiration is its failure to insure the first requisite clear and open airways

The method of resuscitation that has seemed most valuable to us has been the technique of direct exposure intubation and intratracheal insufflation of 10 per cent carbon dioxide and 90 per cent oxygen under measured pressure, as developed by Flagg¹⁶ When the mild measures have been unsuccessful, the baby should be placed on its back on a table It is not necessary for the head to be lowered to 15 degrees from the horizontal, as recommended by Blackley, nor is it wise for the head to be extended over the edge of the table With the infant type of direct vision laryngoscope the

TABLE 4—Deaths of Thirteen Premature Infants

Case	Weight Gm	Condition of Birth	Methods of Treatment	Autopsy
1	1690	Classé cesarean section	pallid weak ery moderate me chanical stimulation carbon dioxide oxygen constantly transfusion of 25 cc of citrated blood died at 9 hours	Autopsy Partial atelectasis
2	1310	Bougie induitioo of labor	mechaoneil intratracheal technic for thirty minutes carbon dioxide oxygen as required two transfusions of 50 cc of citrated blood died on 14th day	Autopsy Atelectasis edema of lung
3	1500	Spontaneous delivery	intratracheal technic difficult left side atelectasis diaphragmatic hernia died at 15 hours	Autopsy None
4	1310	Spontaneous delivery	cyanotic no ery intratracheal technic died at 3 hours	Autopsy Atelectasis
5	1110	Spontaneous delivery	all methods of resuscitation used	stillborn Autopsy Atelectasis
6	1310	Spontaneous delivery (placenta praevia)	mechanical intratracheal technic	stillborn Autopsy Atelectasis
7	1700	Spontaneous delivery	mask (carbon dioxide oxygen) cyanotic atelectasis intracranial hemorrhage died at 3 hour	Autopsy None
8 and 9	1400	(First twin) spontaneous	suction intratracheal technic died at 7 hours	Autopsy Partial atelectasis bilobed right lung
	1900	(Second twin) breech extraction	cyanotic intratracheal technic carbon dioxide oxygen constantly died at 7 hours	Autopsy Incomplete atelectasis bilobed right lung
10 and 11	1350	(First twin) spontaneous	did not breathe mechanical cyanotic died at 14 hours	Autopsy Atelectasis bronchopneumonia
	1370	(Second twin) breech extraction	did not breathe mechan ical cyanotic died at 20 hours	Autopsy Bilateral atelectasis opilation of amniotic fluid
12 and 13	650	(First twin) breech extraction	intratracheal technic died at 13 hours	Autopsy Prematurity
	820	(Second twin) spontaneous	intratracheal technic died at 14 hours	Autopsy Partial atelectasis prematurity

tongue is easily depressed and the larynx exposed The pharynx is quickly cleansed of any mucus with the little sucker, and the laryngeal tube is introduced within the vocal cords and well into the larynx Again, the sucker is used to aspirate any contained matter, mucus or other fluid

When it is ascertained that all obstructive material has been removed, the laryngeal tube is connected with the gas tube and insufflation is begun

It is our opinion that there is a distinct advantage in the intermittent control of gas intake and output An attempt is made not to lead inspiration and expiration but rather to follow the rhythm once it has begun The continuous positive pressure advised by Blackley and Gibberd¹⁷ is the exercise of an artificial dominant

control over the interchange of gases, and inhibition of function may result. Rhythmic and conditioned support of respiratory effort is what is needed.

We believe that the practice of this technic has saved babies when all other methods have been or would have been in vain. We know of no baby that has been or might have been saved after failure of this technic, by the employment of any other method.

INJURY DUE TO INTRATRACHEAL TECHNIC

We have endeavored to ascertain the frequency, extent and consequence of trauma resulting from intratracheal insufflation. In the 160 full term babies there was a known incidence of trauma in six cases, or 3.75 per cent. It is probable that injuries were not evident in other cases. In two cases of spontaneous delivery, evidence of abrasion of the pharynx and trachea was apparent, though both babies were discharged well. Of four cases in the operative group, two babies at autopsy showed tracheal trauma and laryngeal edema, one with pericarditis and pleural and pericardial effusion, the other showed a wide tentorial tear, partial atelectasis, and aspiration of amniotic fluid. In the other two

TABLE 5—*Injury Due to Intratracheal Technic*

Full term spontaneous delivery	
Case 1	Traumatic tracheitis, bronchitis, discharged well
Case 2	Abrasions two on soft palate, discharged well
Full term operative delivery	
Case 1	Larynx and trachea mildly traumatized, intratracheal 1 hour, died at 24 hours
	Autopsy: Pericarditis, pleural and pericardial effusion, trachea intact
Case 2	Pharynx and hard palate excoriated, swollen, oozing fresh blood, pneumonia, discharged well
Case 3	Edema of larynx from trauma causing obstruction, intratracheal for two hours, died at 36 hours
	Autopsy: Wide tentorial tear, partial atelectasis, aspiration of amniotic fluid, trachea not unusual
Case 4	Excoriated posterior pharynx, intratracheal for five minutes, discharged well
Intratracheal technic used in 160 full term infants	
Incidence of injury: 6 cases, 3.75% (It is probable that other patients sustained some minor trauma insufficient however to cause recognizable signs or symptoms)	

babies, both of whom were discharged as well, there were evidences of pharyngeal and tracheal trauma, excoriation and edema. In no case of this series was there proof that the trauma of insufflation was extensive or even a contributing factor in infantile death.

CONCLUSION

More careful study and recording of the factors relative to the incidence, causation and treatment of asphyxia neonatorum should be the continuous duty of every maternity service.

In our opinion, the method of direct exposure intubation and insufflation of oxygen 90-95 per cent and carbon dioxide 5-10 per cent is the treatment *par excellence* because of its ease of application and its beneficent results.

30 East Fortieth Street—520 East Seventieth Street

Yellow Fever in Laboratory Personnel—Unusual precautions are necessary to prevent the infection of laboratory personnel with yellow fever virus from infected mice. Three such infections are known to have occurred. We have considered it necessary to limit the personnel working in the rooms in which the mice are inoculated and the brains removed to persons known to have become immune to yellow fever as the result of an attack of the disease or through vaccination—Sawyer, W. A. and Lloyd Wray. *The Use of Mice in Tests of Immunity Against Yellow Fever*, *J. Exper. Med.* 54: 533 (Oct.) 1931.

THE PHILADELPHIA AND ALASKA STRAINS OF INFLUENZA VIRUS

EPIDEMIC INFLUENZA IN ALASKA 1935

HORACE PETTIT, MD

STUART MUDD, MD

AND

D. SERGEANT PEPPER, MD

PHILADELPHIA

Influenza occurred in mild epidemic form in a number of cities of the United States during the winter of 1934-1935.¹ In and about Philadelphia the disease was prevalent during December 1934 and January 1935. Adults who had been through the pandemic of 1918-1919, as well as children, were attacked. Characteristically the disease was mild but was followed by malaise and fatigability apparently out of proportion to the acute febrile illness. The clinical picture was typical of influenza. There was leukopenia affecting chiefly the polymorphonuclear neutrophils, and in fatal cases hemorrhagic edema of the lungs. Abstracts of two fatal cases representative of a larger number follow.

CASE 1—Rachel R., aged 17, admitted to Bryn Mawr Hospital² Dec. 14, 1934, died December 16, was a high school girl and had had thirteen previous admissions to the hospital because of diabetes. Three days before death the patient had loss of voice and a cough of the productive type with greenish brown expectoration. The second day of the disease the patient became quite dyspneic and felt as if she were choking. At the same time she had fever, severe general malaise and prostration. On the second day of the disease the patient's temperature was 102.2 F. and the maximum temperature the day of death was 103. The pulse varied from 100 to 130 and respirations from 16 to 24. A white cell count on the third day of the disease showed white blood cells 6,300, metamyelocytes 1 per cent, rod nuclears 50 per cent, polymorphonuclears 28 per cent, lymphocytes 8 per cent, monocytes 11 per cent and eosinophils 2 per cent. On the same day the blood sugar was 140 mg. per hundred cubic centimeters and the carbon dioxide 35 volumes per cent. The roentgenogram of the chest on the third day of the disease showed no evidence of consolidation in the lungs. Owing to the great difficulty of respiration a bronchoscopic examination was performed immediately on admission to the hospital. Five small pieces of thick hemorrhagic mucus were removed and cultures were taken. The patient grew steadily worse and died on the early morning of the fourth day of the disease. An autopsy performed six hours after death showed an acute hemorrhagic tracheobronchitis, a diffuse confluent hemorrhage pneumonia resembling grossly, in the judgment of the pathologist, the lesions seen in the 1918 epidemic. Cultures showed few pneumococci and few hemolytic streptococci. *Haemophilus influenzae* was not found. Microscopic examination of the lungs showed intense congestion, serofibrinous infiltration of alveoli with numerous erythrocytes and occasional desquamated endothelial cells, but no polymorphonuclears. Changes typical of an acute hemorrhagic bronchitis were found.

CASE 2—B. S., admitted to the Hospital of the University of Pennsylvania Nov. 27, 1934, had onset of respiratory symptoms November 23, which had become steadily worse. Physical examination revealed many rales but no definite evidence of consolidation. The temperature ranged from 101 to 104. The patient was placed in an oxygen tent. Examination of the sputum showed no pneumococci. Blood examination showed 70 per cent hemoglobin and 6,200 white blood cells, which fell to 2,400 next day. Citrated blood, 200 cc., was given by veno-

² For this case we are indebted to Dr. Max M. Strumia of the Bryn Mawr Hospital.

chysis. The patient became irrational and died on the evening of November 28. The clinical diagnosis was bronchopneumonia (influenzal?).

Examination of the respiratory tract at necropsy disclosed the following. The mucosa of the bronchial tree was extremely engorged and the lumens of the smaller branches were choked with a mucopurulent exudate. The lungs were heavy, each weighed 700 Gm. Both had mottled dusky, smooth surfaces, and a crepitant, boggy consistency. The cut surfaces were very wet and dripped copious amounts of serosanguinous fluid. No definite consolidation could be seen but in many areas a somewhat firmer consistency could be felt.

On microscopic examination of sections from various areas the structure of the lung was found to be obscured by an extensive serous and hemorrhagic exudate containing a varying cell content in different parts of the section. In some areas the alveoli were solidly packed with red cells, elsewhere moderate numbers of large mononuclear cells and polymorphonuclear leukocytes were seen. In still other parts threads of fibrin were mingled with serous fluid. Secondary invasion of staphylococci had taken place. The mucosa of the bronchi was deeply congested and parts had undergone superficial necrosis.

A virus was recovered by Dr. Thomas Francis Jr.³ from the sputum of patients in Philadelphia in the acute stage of influenza. This virus produces experimental influenza in ferrets and mice.

The influenza epidemic of the winter of 1934-1935 in the United States was "characterized² by its small size, its definiteness in all areas except the Pacific, and the rapidity of its spread. The Middle Atlantic section attained its peak in the week ended January 5, and five neighboring sections had peak mortalities during the succeeding week. The West South Central and the Mountain areas had later and less definite peaks. The largest total excess rates occurred in the East South Central, South Atlantic and Mountain regions."

Seattle did not have an outbreak of influenza in the winter of 1934-1935 but there were sporadic cases.⁴ Since Seattle is the gateway to Alaska from the United States, it is probable that the disease was carried to Alaska through that city. Influenza reached southeastern Alaska in the late fall of 1934 and worked its way westward and northward during the winter. Mortality from uncomplicated influenza was not high, but in the associated pneumonias the mortality was great. The statistics reproduced in the accompanying table were kindly furnished in July, 1935 by Dr. W. W. Council, Territorial Commissioner of Health.

Influenza and Pneumonia Mortality in Alaska

	Influenza 1933	Pneumonia 1933	Influenza 1935
First division	6	81	82
Second division	10	21	72
Third division	6	37	245
Fourth division	6	22	46
Total	28	170	445

Autopsies coming under Dr. Council's observation were of postinfluenzal pneumonias. These all showed multiple abscesses and many adhesions between the visceral and parietal pleurae.

¹ Francis Thomas Jr. and Magill T. P. Immunological Studies with the Virus of Influenza. *J. Exper. Med.* 62: 307-316 (Oct.) 1935.
² Newcomb Bryan, M.D. Cf. H. A. Johnston to the commissioner, Seattle per usual communication to the author.

The isolation of communities during the Alaskan winter afforded an unusual opportunity to trace the means of spread of influenza. The disease followed the lines of airplane travel and can be traced from Fairbanks to Nome thence to Kotzebue, thence to Point Barrow and thence (doubling back by dog sled) to Wainwright.

Influenza reached Fairbanks on Jan. 15, 1935. There were approximately 500 cases with five deaths all due to postinfluenzal bronchopneumonia. The Fairbanks epidemic was comparatively mild with few complicating pneumonias, but the estimated mortality from the pneumonias that occurred was about 50 per cent. During the winter months, two or three airplanes fly each week between Fairbanks and Nome.⁴ There is also air travel between Nome and Kotzebue approximately every ten days. Influenza began in Nome after the outbreak in Fairbanks and was carried to Kotzebue, where it per-

Points in Alaska involved in the 1935 epidemic of influenza

sisted until the first part of May. There were no deaths in Kotzebue, but the morbidity was high.

On April 8, 1935, a party of three men⁵ left Fairbanks by air for Point Barrow by way of Kotzebue. A stop of several days was made at Kotzebue during the time of prevalence of influenza there. Influenza appeared in Point Barrow on April 15.⁵ None of the party contracted influenza. The assumption is that one or more acted as healthy carriers to the Eskimos. The morbidity at Point Barrow was high, with a mortality of fifteen persons, mostly old Eskimos, in a population of about 300. The epidemic started at Wainwright, 90 miles southwest of Barrow, about ten days after it reached Point Barrow and is attributed to a party of Eskimos who went from Barrow to Wainwright by dog sled. Some of these became ill with influenza on the trip, others after their arrival. There were no deaths at Wainwright although the morbidity was high.

³ Gillespie, Floyd Burke, M.D., Fairbanks, Alaska, personal communication to the author.

among the 200 Eskimos. The difference in mortality between Point Barrow and Wainwright may have been due to the difference in the treatment of the patients. At Wainwright each patient was required to remain in bed in his own igloo until he recovered. At Point Barrow the patients crowded to the doctor's office every day even when they had high temperatures, some coming over the ice from outlying igloos. Point Hope which was isolated by its location and little if at all visited during the epidemic period, had no influenza.

At the request of Dr R R Hyde of Johns Hopkins Hospital Dr Greist of Point Barrow collected throat washings from influenza patients preserved in 50 per cent glycerin. These were brought out to Fairbanks by Dr F B Gillespie who gave them to Pacific Alaska Airways for shipment to Baltimore. The virus was recovered from these samples pooled by Dr Thomas Francis Jr of the Rockefeller Institute for Medical Research.

Samples of convalescent serum were obtained by Drs Pettit and Pepper from sixteen Eskimos and one white man at Kotzebue. Three of these patients were 17 years of age or younger. The others were all old enough to have been through the 1918 epidemic, which visited Kotzebue as well as other Alaskan towns. Drs Pettit and Pepper had been sent by the Department of Bacteriology of the University of Pennsylvania School of Medicine to collect serum and virus, but as it turned out acute cases as a source of virus were not available on their arrival. Their flight to Alaska was in part contributed by the Pan-American Airways in cooperation with the United Airlines and the Alaska Steamship Company. They completed their trip of eleven thousand miles in fifteen days from Newark to Newark. The convalescent serum has been distributed to the several laboratories currently engaged in influenza research. Some has been preserved in "lyophile" form⁶ for later test.

Reports of comparison of serums collected in Great Britain with serums from the Philadelphia and Alaska epidemics have been published by Andrewes, Laidlaw and Wilson Smith.¹¹ Reports of comparison with other serums from America will be published by Francis and Magill.⁸ The data obtained lend themselves to the following interpretation.

About half the adults in the British and American urban populations thus far sampled have protective antibodies against the influenza virus at present prevalent in those countries. Those attacked are individuals with less than average humoral resistance; these individuals, however, in early convalescence from attack develop protective antibodies.

The Alaskan influenza virus obtained from Point Barrow in April 1935 has been shown by Francis⁹ to be immunologically identical with the virus recovered by him from Philadelphia cases in January 1935 and from the epidemic in Puerto Rico in September 1934.¹⁰ These New World strains appear to be immunologically identical also with strains recovered in Great Britain in 1933, 1934 and 1935 by Laidlaw, Andrewes and

Wilson Smith.¹¹ A virus has also been recovered by Burnet¹² from an epidemic in Melbourne, Australia, in June 1935. This strain is neutralized by high dilutions of horse antiserum against the British W S strain. The virus strains recovered from human influenza have been shown to be immunologically related to but not identical with the virus of swine influenza.¹³ There is much evidence to suggest that the swine virus may be the pandemic strain of 1918 adapted to swine.¹¹

The virus that has been the primary etiologic agent of human influenza in widely separated areas of the world during recent years would appear, then, to be a single immunologic entity. Both active and passive immunization of susceptible animals against this virus have been shown to be possible. These facts should offer profound encouragement for the ultimate control of this last and greatest uncontrolled pestilence and should challenge the best efforts of preventive medicine to perfect practicable means of active and passive immunization before the coming of the next pandemic.

THE TREATMENT OF CIRCULATORY FAILURE

LOUIS M WARFIELD, MD

MILWAUKEE

For many years it has been taught that in infectious fevers, when the pulse becomes rapid and tends to be thready and the heart sounds become muffled, the heart is failing. Heart stimulants are indicated, for one must support by all means the failing heart. When one turns to textbooks on medicine in the sections on treatment of the various infections one finds it stated that when the heart fails cardiac stimulants should be administered, the chief of which is digitalis in some form. Others such as caffeine with sodium benzoate, camphor and epinephrine, are mentioned. This idea has been taught for so many years that it has become almost axiomatic. Physiologists have known that this is not true and as long ago as 1899 Romberg and Paessler¹ showed in animal experiments that the heart does not fail even in fatal infections with the diphtheria bacillus, pneumococcus and streptococcus.

When bacteria invade the body and set up disease, certain histamine-like substances are formed, which circulate in the blood. From the work of Dale and Laidlaw² it is known that histamine produces arteriolar precapillary contraction with capillary dilatation, a condition known as secondary shock. If the capillary dilatation is great enough, the animal bleeds to death into its own vessels.

The first result of any infection with bacteria is increase in the body temperature, which increases body metabolism. The pulse rate increases slightly or greatly, the blood flow is increased in order to take care of the increase in metabolism. The minute output is greater

The blood pressure may or may not be influenced, but it is apt to be slightly reduced, as the result of mild vasodilatation. The veins are full, return flow to the right auricle is not disturbed and the circulation becomes adjusted to the abnormal conditions. This is the circulatory response to all mild or moderately severe infections. One does not interfere by giving various drugs, if one is wise, for the body seems fully capable of restoring itself to health without active assistance. The great majority of infections belong to this group. Venous return flow is adequate to produce ventricular filling.

Now, a step further and the infection becomes severe, the pulse becomes more rapid and smaller, the blood pressure drops, the first sound at the apex of the heart becomes faint. These are the usual textbook signs of the failing heart. Now let us ask what has happened. Are these signs of a failing heart or are they signs of peripheral dilatation? Is it conceivable that an organ with such a reserve power as the heart has, an organ that, given oxygen and dextrose and insulin, can beat almost indefinitely outside the body, an organ that beats from before birth to old age, is likely to fail within a few days or weeks? Isn't it much more probable that the explanation for the so-called failing heart is to be found elsewhere than in the heart itself?

Strong muscle contraction depends on the load placed on it. Starling's law is that the strength of a muscle contraction is dependent on the length of the fibers. This holds true unless the muscle is overstretched. Heart muscle is no exception to this rule. The stimulus is always the same, but the strength of contraction depends on the diastolic filling of the ventricles, particularly the left ventricle, with blood. This assumes an adequate, constant venous return flow from the periphery.

The volume of blood in circulation then takes on great interest. The blood in the body is not all circulating all the time, so that what is important is the actual circulating volume of blood. There are huge depots, storage areas, where great quantities of blood can stagnate and be wholly useless as a carrier of oxygen. The liver, the splanchnic area, the subcapillary capillary skin plexus⁴ normally are the great storage areas. Under pathologic conditions the lungs can hold out a large amount of circulating blood.⁵

In recent years it has been learned that the one condition common to both primary and secondary shock is decreased circulating blood volume.⁶ As Moon has recently tersely stated the problem: "The shock syndrome results from a disparity between the volume of blood and the volume capacity of the vascular system."

Experiments performed by many investigators have shown that in secondary shock there are (1) decreased blood volume (2) lowered blood chlorides (3) hemoconcentration and (4) lowered arterial blood pressure.

It has been shown that increase in chlorides favors phagocytosis and this increase may be as little as 0.01 per cent.⁷

Since adequate venous return flow which produces diastolic filling is absolutely essential to good heart contraction it follows that when the histamine-like substances formed in severe infections produce marked

dilatation of capillaries, much blood will be held out of circulation. Further, the toxic products of bacterial action on tissue cells cause increased capillary permeability, so that fluid exudes into the tissues and because of stasis is not reabsorbed.

Thus water is lost in the tissues and blood is concentrated. It follows logically that venous return flow must be decreased and the heart receives less blood to pump. But the circulation must be maintained. The heart then beats rapidly in order to keep up the minute volume, but a less than normal amount is thrown into the aorta at every systole. The heart beats faster and faster, the pulse becomes smaller and smaller. Severe parenchymatous degeneration, which is largely water imbibition in the cells, takes place, thus further reducing blood volume. The heart now is embarrassed. It is doing its best to keep up the minute volume of the circulation against a dilated periphery and with less forceful beats because the ventricle is not stretched at each diastole. In fact, the heart instead of dilating actually becomes smaller. Now another factor enters the picture. The heart has its blood supply from the coronary arteries. During diastole the coronaries are filled.⁸ The only recuperating time of the heart is in diastole. When the heart beats rapidly and weakly because it has less and less blood to force out, the coronaries receive less and less blood and the recovery time for muscle nutrition becomes shortened. The heart must have oxygen and dextrose in order to beat. It is almost impossible to deplete the heart of dextrose, but the oxygen becomes less and less. Anoxemia, lack of oxygen, is the only known condition that produces dilatation of the heart.⁹ (I am not discussing heart failure in heart disease.) Just before death the heart dilates, it gets too little oxygen. The pathologist at autopsy sees the dilated, flabby heart and he has said for years that the heart is dilated in acute infections. He is wrong. As long as there is during life sufficient venous return flow, sufficient oxygen for the heart, the heart does not dilate. Dilatation is the antemortem failure of the heart caused by collapse of the peripheral circulation.

When Romberg and Paessler¹ showed in 1899 that the functional capacity of the heart was not materially changed in severe experimental infections they thought that vasomotor tone was lost. Since then many investigators have shown that there is no loss of vasomotor tone. The absolutely essential factor is decreased circulating blood volume due to stasis in the storage areas and transudation into the tissues as the result of increased capillary permeability.

Many physicians have seen the lungs in a case of rapidly fatal influenzal pneumonia. They are enormous, do not collapse and are so full of fluid that they drip when taken out of the thorax. One can wring water from them as one wrings water from a soaked sponge. Everywhere are petechial hemorrhages showing capillary damage. Underhill¹⁰ found that in the influenzal pneumonia patients the blood concentration was so great that hemoglobin estimations as high as 140 per cent were not infrequent. How can the heart carry on the circulation when the blood is so concentrated that it cannot flow back into the ventricles in sufficient quantity to stretch them?

PATHOLOGY

Congestion of abdominal viscera and increased moisture in the various organs have been repeatedly observed by prosectors in the bodies of persons dying of all types of infection. The significance of the increased wetness has not been sufficiently appreciated. In both experimentally produced secondary shock and in that of death from infections, similar microscopic observations are made. There are marked dilatation and engorgement of the capillaries and venules in all the organs, particularly the intestine. Tissue edema is present in greater or lesser degree and petechial hemorrhages show capillary damage. The capillaries would appear to be more permeable to fluid transudation. Loss of fluid produces hemoconcentration. Moon¹¹ says

The shock syndrome results most frequently from dilatation of capillaries and venules plus leakage of plasma through capillary walls whose permeability has been increased. This feature has been present in shock from diverse causes. In the experiments which produced low blood pressure by simple vascular dilation without capillary injury, shock did not result. A simple loss of blood or of plasma, the vascular walls remaining normal, does not progress but tends to restoration by physiologic processes. Fluid is absorbed from the tissues, or that supplied therapeutically is retained in the circulation. In shock the reverse is true. Fluid is neither absorbed nor retained and further loss by vomiting, diarrhea, effusion and by edema is progressive.

One concludes that increased capillary permeability is an essential factor in the mechanism by which shock progresses.

TREATMENT

Since the heart itself does not fail but the peripheral circulation collapses and blood volume and venous return flow to the heart are lessened, the logical treatment would be to increase the blood volume or venous return flow in any way possible. There are three methods by which one may theoretically accomplish this end: (1) postural or mechanical, (2) by employing fluids intravenously, (3) by employing drugs that act on the peripheral vessels, either to constrict them or to decrease capillary permeability or both.

1. Many years ago I¹¹ could show that in typhoid, when the pulse became rapid and of low volume, elevation of the foot of the patient's bed was often sufficient to reduce the pulse rate and increase the volume. When the pulse became faster and smaller I used to bandage the legs from the ankles to mid thigh. This too seemed to be helpful in some cases. At that time (1910-1912) little was known about blood volume and peripheral collapse but it seemed to me that the heart was not getting sufficient blood in venous return flow. Bandaging of the legs was purely empirical. It has since been shown (Wollheim) that one can increase the circulating blood volume 1,000 cc by this procedure. The postural treatment can obviously be used only when patients are comfortable, flat on their backs. In people ill with typhoid this treatment was satisfactorily used.

2. One would consider, immediately on being told that blood volume should be increased, that intravenous administration of isotonic fluids should be used. This appears to be good reasoning. What should one use and how much? One should bear in mind that the normal resting body loses from 2,500 to 3,000 cc in twenty-four hours. Sweating, vomiting, diarrhea and increased respiratory rate cause greater loss, so that from 1,000 to 2,000 cc daily is frequently not enough to make up water loss. We live in water and we should appreciate the deleterious effects of dehydration. As there is a

tendency to lessened chlorides in the blood, salt solution is useful. As patients who are so ill that they need intravenous treatment do not take much by mouth, 10 per cent solution of dextrose is useful. There is one flaw in this treatment. When the peripheral collapse is so severe that capillary permeability is increased, salt solution tends to pass out of the circulation and further to increase the tissue edema. Dextrose does not pass out so rapidly. In cases of severe collapse 50 cc of 50 per cent dextrose is more logical treatment than 250 cc of 10 per cent dextrose, the latter may pass out of more permeable capillaries and increase edema of the lungs. Acacia solution has been recommended. I have had no personal experience with it. I have been afraid to use it. Recently some work has been published which has shown that acacia often is harmful.

Some physicians like Ringer's solution better than physiologic solution of sodium chloride. If there is much vomiting and diarrhea, it would be a preferable solution to use.

Since it is wished to increase blood volume and to prevent transudation of fluid into the tissues, the most efficacious fluid to use is blood. Blood transfusion, in my opinion, has no value in introducing any curative substances to combat the infection. Its sole effect is to increase the effective circulating blood volume and thus give support to the heart. The proteins of the blood keep up the osmotic pressure within the capillaries so the fluid is not so easily lost to the tissues. Further, it dilutes the blood in circulation and reduces hemoconcentration. It prolongs the time for the body to make its own antitoxins or other immune substances. I can not see that it makes any difference whether one uses whole uncitrated blood or withdrawn citrated blood. If one can neutralize the toxins of any infection by the use of antitoxin, the capillary transudation ceases, fluid is again normally reabsorbed, blood volume is increased, venous return flow is increased, and the heart becomes slower and beats more forcefully. The infection is overcome, the patient is cured.

3. It has been my experience that as soon as a hospital intern is called to a febrile patient, especially following some operation, whose pulse is becoming rapid, he orders digitalis (usually digifolin) or caffeine with sodium benzoate. He is following his textbook or his teachers, one cannot blame him.

Digitalis has its very definite place in heart disease. No drug is so useful. But when there is no heart disease digitalis has no place in the doctor's armamentarium. Digitalis does stimulate the heart to increased contraction, it tends to keep the heart muscle from over dilating and it acts on the vagus endings under certain conditions. However, those effects are not useful to the patient whose peripheral circulation is in collapse. Further digitalis is potentially harmful because it decreases blood volume (Wollheim). Surely digitalis is not the drug to use in acute infections.

Caffeine with sodium benzoate is a favorite drug. Sollmann and Pilcher¹² have shown that caffeine is a vasodilator acting as an inhibitor of vasoconstriction. This does not appear to be a useful drug.

Metrazol and coramine are two new so-called heart stimulants. I am not convinced that either is of any real value, besides, we do not want heart stimulants.

What we most want is some drug that will (1) tend to increase blood volume, (2) stimulate oxidative processes, (3) increase phagocytosis and (4) decrease capillary permeability. Have we such a drug? Possibly

¹¹ Warfield L. M. The Treatment of Circulatory Failure. *Ann Int Med* 9:51 (Feb.) 1934.

¹² Sollmann Torald and Pilcher J. D. The Action of Caffeine on the Mammalian Circulation. *J Pharmacol & Exper Therap* 3:19 1911.

we have not the ideal drug, but the drug which has all these actions is strychnine. I have used it for many years, used it in relatively large doses, from one-twentieth to one-fifteenth grain (0.003 to 0.004 Gm) hypodermically every two to three hours. During the influenzal pneumonia epidemic of 1918 I felt that I saved lives with it. Professor von Jagic in his recent book says that he used it extensively in influenzal pneumonia and found it most efficacious. Others have used it in various infections. I can highly recommend it.

Two other drugs are useful in constricting capillaries. These are epinephrine and pitressin. The former acts through the sympathetic nerves on the muscle walls of the arterioles and its action is transient. It is most useful in sudden collapse. The latter acts on the muscle walls directly and has a more prolonged action. Hartl¹³ injected pitressin into men and studied its effect on the circulatory and respiratory systems. There was found an increase in the systolic and diastolic blood pressure, in peripheral resistance and in amplitude of the pulse with augmentation in the ventilation of the lungs. There was a lessened membrane permeability and an increase in the oxygen debt during work. It is said that the effect of a hypodermic injection lasts from two and a half to three hours. It is the better peripheral stimulant. It can be given in doses of from 0.5 to 1 cc hypodermically every three hours.¹⁴

Whenever there is cyanosis, be it in pneumonia or any other serious bacterial infection, oxygen should be given in sufficient quantity to reduce the cyanosis. The nasal catheter method, now so generally employed, is as good as or better than the tent method. Oxygen properly administered not only reduces cyanosis and hence reduces anoxemia but slows the heart, lowers the temperature and probably by reducing anoxemia in the tissues, decreases capillary permeability, thus reducing transudation into the tissues.

SUMMARY

It is not the heart that fails in acute infections, the peripheral circulation collapses, so that the heart has no blood finally to pump. The condition is analogous to secondary shock.

The heart usually becomes smaller in acute infections until just before death, when it dilates because of anoxemia.

Digitalis is not a useful drug in these cases of peripheral circulatory failure.

Measures to increase blood volume such as intravenous administration of sufficient quantities of physiologic solution of sodium chloride, dextrose or Ringer's solution or direct or indirect blood transfusions should be used. Drug therapy, up to the present time, is limited to strychnine, pitressin and epinephrine.

Whenever there is evidence of anoxemia (cyanosis of the nail beds and so on) oxygen should be given in sufficient quantities to overcome the cyanosis.

Patients with severe infections cannot all be saved but it is believed that more can be saved by using the procedures outlined than by the methods still described in textbooks.

425 East Wisconsin Avenue

INTESTINAL OBSTRUCTION DUE TO A HOLE IN THE MESENTERY OF THE ASCENDING COLON

PASSAGE OF DESCENDING COLON AND SIGMOID THROUGH DENSE RING IN MESENTERY OF ASCENDING COLON

THOMAS S. CULLEN, M.B.

BALTIMORE

In an article on acute intestinal obstruction due to mesenteric defects, requiring massive resection Edwards¹ says "The passage of a loop of small bowel through this abnormal opening in the mesentery is probably the rarest of all factors responsible for intestinal obstruction."

Edwards reports that "Brown² in 1920 summarized twenty cases of this malady, and Cutler³ in 1925 tabulated data concerning these cases and eight others." Edwards also refers to cases recorded by Elston,⁴ McWhorter,⁵ Judd⁶ and Hamaker⁷ and says "The opening is usually just mesial to the artery supplying the terminal part of the ileum, the appendix and the first portion of the cecum. This accounts for the fact that the terminal part of the ileum and the cecum are not included in the gangrenous process."

Edwards then reports two cases coming under his care. In each extensive resection was necessary. Both patients recovered. His article is well worth reading. His conclusions are as follows:

- 1 Abnormal openings in the mesentery are rare.
- 2 They are usually of congenital origin.
- 3 Injury has not been demonstrated as an etiologic factor in many instances.
- 4 The openings are most frequently located in the mesentery to the ileum within 2 or 3 inches of its junction with the cecum.
- 5 When intestinal obstruction results, massive resections are likely to be required.
- 6 Early diagnosis of intestinal obstruction and immediate operation will reduce the mortality.

On only one other occasion have I seen intestinal obstruction due to a hole in the mesentery. This was during my intern days at the Toronto General Hospital. The patient was an elderly man who was suffering from an acute obstruction. The waiting policy was the rule in those days. The patient lived for nearly a week.

At autopsy a hole was found in the mesentery of the small intestine and through this a loop of small bowel had passed. The incarcerated bowel showed little change and, even at autopsy, could be drawn back with ease.

According to Edwards, there were only two cases in which obstruction of the large bowel occurred, those of Judd and of Hamaker. In the present case there was a ringlike opening in the mesentery of the ascending colon. This ring was about 2 cm in diameter and its walls were very firm. Redundant descending colon

14 Charles M. Gruber and William B. Mount. (Some Observations on the Effect of Pitresin upon the Cardiovascular System. J Pharmacol & Exper Ther 29 445 (Aug) 1930) obtained vasoconstriction of coronary arteries in normal rabbits, frogs and dogs with pitresin in the perfusion fluid. At a time in a reduced increase in volume of the dog's heart when it was injected intravenously. This does not mean that the heart of a patient who is ill with some acute infection will necessarily be in the same way as the heart of a normal dog. Pitresin has seemed to be a valuable drug in cases of peripheral collapse in infectious fever.

15 The patients have recovered in spite of this because of its use.

and sigmoid passed over to the right, passed through the ring-shaped opening could not get back and became obstructed. Extreme tension of the mesentery of the distended bowel by pressure had produced blockage of the vessels of the lower portion of the ileum and had caused death of more than 5 feet of the distal portion of the small bowel, so that not only obstruction

Fig 1—Intestinal obstruction due to a hole in the mesentery of the ascending colon. General view of the abdominal viscera as found at operation. The small picture at the upper left shows the three incisions made during the operation. Incision 1 was a gridiron incision made for removal of the appendix. Black bowel large size appeared whereupon the midline incision (2) was made. Incision 3 was made at the end of the operation and the sigmoid attached at that point to be opened later if necessary. The large picture is a semidiagrammatic representation of the abdominal condition as found at operation. The large hemorrhagic bowel proved to be a loop of descending colon and sigmoid flexure passing through a dense hernial ring in the mesentery of the ascending colon. This caused marked tension on the mesosigmoid resulting in constriction of the terminal mesentery of the small bowel sufficiently severe to cause stasis of its circulation and resulting in the destruction of more than 5 feet of small bowel to a point within a few centimeters of the ileocecal valve. This black bowel is shown filling the pelvis while the normal bowel light in color is drawn upward.

of the large bowel but also necrosis of much small bowel had to be dealt with.

I am indebted to my friend Max Broedel for his schematic illustrations and for the clear manner in which he shows the most likely cause of the rapid necrosis of so much small bowel.

REPORT OF CASE

History.—Shortly after 8 on the morning of Feb 5 1935 Dr Harry Wilson of Baltimore asked me to see his son, who was 11 years old. The boy's general health had always been excellent and he never had had any serious illness. The only past symptoms that might be connected with the present illness were four or five attacks of abdominal pain of short duration which were always relieved by vomiting. These attacks had been scattered over a period of two or three years and were thought to be due to indiscretions in diet.

For several years he had complained of pains in the right side of the abdomen after running and of pains in his legs after any strenuous exercise.

Three months before, after playing football, he complained of rather severe pain in the lower part of his abdomen. This, however, lasted only five minutes.

Although he was accustomed to violent exercise in various forms, it was noted that after this attack he was less inclined to participate in any strenuous play. This, he said, was due to the fact that his legs hurt him and became tired afterward.

During the past three months he had appeared tired and on occasions, without apparent reason, had turned pale and even become "faint." However, he had usually looked well, had eaten and slept well, and had had normal bowel movements without laxatives.

One month before, after a long bicycle ride he became very faint and the next day had an acute attack of abdominal cramps which lasted about half an hour. These were relieved by vomiting.

On the day before I saw him he had taken no unusual exercise, had eaten moderately and had had a normal bowel movement before retiring at 9 p m.

At 1 a m he was heard to be "sleeping heavily and snoring in an unaccustomed manner." He awoke about 2:30 a m with moderate pains in the abdomen. These gradually became worse, but he did not report to his parents until 6:30 a m. Dr Wilson said that at this time the pains were rather acute, paroxysmal in character and generalized. The temperature was 99 F, the pulse 90. There was no localized tenderness and no muscular rigidity. Some nausea was present and the boy made several attempts to vomit. Enemas were ineffectual except in bringing away a slight amount of mucus.

I saw the boy with Dr Wilson at 8:30 and we both agreed that he should be sent to the hospital at once.

Operation and Result.—The operation was performed at the Church Home and Infirmary at 9 o'clock. Since the symptoms suggested an acute appendicitis, a gridiron incision was made and bluish black bowel was at once encountered. Immediately a midline incision was made and a hole about 2 cm in diameter

Fig 2—General view of the abdominal viscera after operation. The evacuated hemorrhagic loop of sigmoid was temporarily laid aside in order to determine to what extent it would recover. The gangrenous small bowel was then removed, the ends were closed, the appendix was removed as it was in the way, and a lateral anastomosis was made between the small bowel and the cecum. The two stumps of small bowel were covered over by approximation suture as indicated. By this time the hemorrhagic sigmoid with its mesentery had apparently recovered to such an extent that it was considered wiser to leave it alone. It was however stitched to the peritoneum of the gridiron incision on the left (incision 3, fig 1) to be opened later if necessary.

was found in the mesentery of the ascending colon. Through this a loop of large bowel had passed and had become markedly distended (fig 1). The mass was bluish black and could not be drawn back because of the accumulation of fluid. Accordingly

a purse-string suture was placed at the most distended part of this loop and a small trocar was then introduced. The contents were rapidly emptied, they consisted in large measure of blood. The purse-string was immediately tied and then reinforced with three or four mattress sutures. Not one drop of the bowel contents escaped.

The loop of formerly distended bowel was now readily drawn back through the opening in the mesentery and was then pushed over to the left, because there was evidence of further trouble in the abdomen.

A large amount of the small bowel was black, but the peritoneal covering was still smooth and glistening. This black portion was followed upward until normal bowel was reached again. At this point there had been some constriction. We then clamped doubly, cut across the bowel with a cautery and removed the small bowel until a normal portion was again reached at a point within a few centimeters from the cecum. The removal of the bowel suggested very strongly the way in which the bowel is removed at autopsy. It had to be done very rapidly.

A physician who was watching the operation, wishing to determine just how much bowel had been removed, lifted it up, and even in its convoluted form it was over five feet in length.

Both ends were closed and the appendix was then removed, as it was in the way. A lateral anastomosis was made between the small bowel and the cecum (Fig 2), the opening being rather smaller than usual, so that the contents of the small bowel would not pass too rapidly into the cecum.

An examination was then made of the redundant descending colon, which had been herniated through the mesentery. Its color was infinitely better, and although the mesentery of this area showed a good deal of hemorrhage, it seemed wiser to let well enough alone (fig 3). This part of the bowel, however, was brought up to a left gridiron incision and tacked to the peritoneum so that it could be opened promptly if necessary, and so that the sigmoid was fixed in such a way that it could not possibly get loose and again pass through the ring in the mesentery of the ascending colon. The margins of the ring were so hard and so rigid that the ring could not be closed.

One cigaret drain was left in the lower portion of the midline incision. The gridiron incision on the right and the gridiron incision on the left were closed.

At the beginning of the operation the outlook seemed hopeless but the patient stood the operation fairly well. At the end of the operation his pulse was fair although rather rapid. It was 136.

Postoperative Progress—As the outlook in this case necessarily was not good, the postoperative course is recorded somewhat in detail.

February 5 the patient was given 700 cc of 10 per cent solution of dextrose intravenously in the operating room. He was returned to his room and given 400 cc of citrated blood intravenously. Intramuscular infusion of physiologic solution of sodium chloride was started and 350 cc was absorbed. The patient came out of the anesthesia in good condition. His pulse varied from 124 to 146 but was strong and of good quality. His temperature during the day varied from 102.6 to 103.6 by rectum. Codeine was used as a sedative.

February 6 the patient had a fairly comfortable night. As he was beginning to have some abdominal distention the rectal tube was passed at intervals and bloody mucoid material obtained. This procedure gave relief. Ward inhalations were started because of the cough which the patient had had before operation and which had become worse. The temperature during these twenty-four hours varied from 101.6 to 105 by rectum. The pulse varied from 124 to 148 but was of good quality. Seven hundred cc of 10 per cent solution of dextrose and physiologic solution of sodium chloride was given intravenously in the morning and repeated later on in the day.

February 7 the patient had been more comfortable except for mucus in the throat from pharyngitis and bronchitis. Severe upper abdominal distention was relieved by the passage of the intranasal stomach tube twice during the day, each time a large amount of gas and dark green fluid was aspirated. The patient refused to allow the tube to remain in place all the time but had no objection whatever to its introduction as often as was necessary. The rectal tube was passed several times and a bloody mucoid material was obtained. A small amount of flatus was expelled through the rectal tube on one occasion.

The pulse was between 108 and 124, and the temperature between 99.2 and 100.6 by mouth. The general condition was greatly improved except for the recurrent distention of the stomach and the mucus in the throat. Seven hundred cc of 10 per cent solution of dextrose and physiologic solution of sodium chloride was given intravenously at 3 a m, 9 a m, 5 p m and midnight.

February 8 the patient was expelling large quantities of gas by rectum. There was no bloody discharge from the rectum. The abdominal distention was relieved by the passage of the stomach tube on two occasions. The patient was given small amounts of liquid by mouth. The pulse varied from 118 to 94, the temperature from 99.8 to 100.6 by mouth. Seven hundred cc of 10 per cent solution of dextrose and physiologic solution of sodium chloride was given intravenously at 2 30 and at 10 30 p m.

February 9 the patient had had a very comfortable night. He expelled gas freely and had a normal, formed stool. He was given liquid diet in small amounts and also a small piece of beefsteak. His pulse was 92, the temperature ranged between

Fig 3—Diagrammatic representation of the probable cause of the speedy destruction of more than 5 feet of small bowel. It seems obvious that the chief factor was the ring-shaped opening in the mesentery of the ascending colon (shown by arrow) where the fusion of the embryonic large bowel and its mesentery with the parietal peritoneum had remained incomplete. Any ring of such a character in the abdominal cavity is a potential source of danger threatening intestinal obstruction. Another factor was the marked mobility, redundancy and laxness of the descending colon and sigmoid. Under ordinary circumstances this bowel could never have reached the ring. It is a wonder that the small intestine was not caught on some occasion but the ring was probably large enough to permit a normal, small intestinal loop to slide in and out without getting caught. Glance at the vessels in the mesentery of the small bowel as they pass beneath the loop of large bowel which is to follow the arrow out through the ring beneath the ascending colon to become constricted and distended as indicated in figure 1. The more it was distended the more taut became its mesentery. This taut mesentery caught the mesenteric vessels of the terminal ileum as in a vise affecting the venous circulation more than the arterial thus causing passive hyperemia and then death of the small bowel. This vise consisted of the taut mesentery of the sigmoid on the one side and the resisting lumbar vertebrae and the sacral promontory on the other.

99.4 and 100.6. Seven hundred cc of 10 per cent solution of dextrose and physiologic solution of sodium chloride was given intravenously at 11 a m and 7 p m.

February 10 the patient was much improved and was taking liquid diet well. To this lactose was added, he also had buttered toast and milk shakes. He was passing gas and fecal matter by rectum. The dressing was changed and the drain shortened. The pulse range was from 88 to 96. The temperature was from 99 to 100.4 by mouth. At 5 p m 800 cc of 10 per cent solution of dextrose and physiologic solution of sodium chloride was given intravenously.

February 13 the patient's condition was still improving, all black stitches were removed.

February 17 the patient had a formed stool, the silkworm-gut stitches were removed. A wet dressing was put on the incisions, as there was a small amount of purulent discharge.

February 22 the patient was up and walked.

February 26 the patient was discharged in excellent condition. His incisions had healed completely.

Nov. 10, 1935, Dr. Wilson told me that his son had been in good health ever since leaving the hospital. It is with much difficulty that he curbs the boy's desire to take part in strenuous athletics. Now and then the boy will look a little pale for a moment or have a slight feeling of faintness. He has always been fond of fruit but now he craves it. He will eat six apples at a time and if a can of pineapple is within reach, he will finish it at one sitting. He is now (says Dr. Wilson) making unusual progress at school. The patient's bowels are regular and the stools normal, but following the formed stool there is very occasionally a little diarrhea, which Dr. Wilson thinks can be accounted for by the excessive amount of fruit the boy eats.

As I look back on this case it becomes more and more evident that Dr. Wilson's prompt action saved his only son's life. Delay of a few hours would have told a different story.

25 East Eager Street

PERIARTERITIS NODOSA

WITH REPORT OF CASE SHOWING UNUSUAL
FEATURES AND APPARENT RECOVERY

LYLE MOTLEY, M.D.
MEMPHIS, TENN.

Kussmaul and Maier¹ in 1866 first accurately described a definite inflammatory disease of the medium and small arteries. Since then this relatively rare disease has been reported at intervals until a fairly voluminous literature has accumulated on the subject, containing reports of extremely varied clinical manifestations. Ophuls,² in an article on the subject in connection with the report of a case in 1923, found seventy cases recorded to that time, and Rothstein and Welt³ found 195 cases recorded to 1933. I have been able to find an additional twenty cases in the literature.⁴ While a critical review of some of the cases reported might leave some doubt as to their being true periarteritis nodosa, since other vascular lesions can be confused with those of this disease,⁵ nearly all the cases

reported so closely conform in their pathologic characteristics that there is little doubt that the disease exists as a pathologic entity.

PATHOLOGY

The changes consist of an inflammatory process involving, in different stages and in different degrees, all the coats of the medium and small arteries with perivascular inflammatory changes. In all the cases there is a marked infiltration of the vessel walls with polymorphonuclear neutrophils and to a lesser extent with lymphocytes. Extensive vascular and perivascular infiltration with eosinophils has been reported at times, as in Ophuls'² case and my first case. There is exudation and later necrosis resulting in aneurysm and thrombosis, and frequently the small aneurysms rupture, causing either frank hemorrhage or hemorrhagic extravasation. When the process extends to the intima the smaller vessels become occluded. Marked involvement of the veins has been noted, though only rarely.⁶ Multiple aneurysms apparently are very pronounced in some cases and almost absent in others.⁷ The interference of blood supply by vascular occlusion causes secondary pathologic changes in various organs and tissues, characterized by necrosis, infarction, fatty degeneration and the like, the character and extent of which determine the symptoms referable to these organs.⁸ Almost any secondary tissue changes can occur, such as the unusual and marked involvement of mucous and serous membranes reported in one case.² Bony tissue apparently is almost free from involvement, though this has been reported at least once.⁹ However, some systems are decidedly more frequently involved than others, and the kidney seems to be the organ most often involved, appearing as high as 80 per cent in one series studied.¹⁰ An exhaustive discussion of the different types of pathologic changes appear in Arkin's article.

ETIOLOGY

To the present time the etiology is unknown though generally considered of infectious nature.¹¹ Of the various organisms considered, the streptococcus has been implicated more frequently than any other, though the possibility of the disease being of syphilitic nature has been seriously considered by several writers. The failure of the disease to respond in any definite degree to antisyphilitic treatment and the inability in any instance to demonstrate the spirochete within reason eliminate syphilis as a cause. Much experimental work has been done. Vasiliu and Iriminoui¹² isolated a nonhemolytic streptococcus from involved tissues but were unable to reproduce the disease in animals. Harris and Friedrichs¹³ in a series of animal experiments concluded from positive results that the cause

is a filtrable virus Von Haun,¹⁴ by inoculation of material from human cases produced the arterial changes of the disease in animal experiments, but no organisms could be recovered from the diseased animals. Carling and Hicks¹⁵ repeated Von Haun's experiment with negative results. By inoculations of material from five cases Franz¹⁶ failed to transmit the disease to animals and believed it not a specific disease but secondary to many different infections. By blood and tissue cultures various organisms have been recovered by different workers from patients with the disease, particularly *Bacillus coli* and streptococci.¹⁷ By many writers the association of periarteritis with other diseases is mentioned among which is scarlet fever, Friedberg and Gross¹⁸ having found it following scarlet fever in two of eight cases. Many writers call attention to the apparent relationship of periarteritis to rheumatic fever, and some believe that rheumatic infection is a common cause of the vascular lesions.¹⁹ Some cases have apparently definitely followed an attack of acute tonsillitis.²⁰ In one series that came to autopsy Aschoff bodies were present in the myocardium in six of thirteen cases.¹⁹ However, very few of the cases reported previous to 1934 showed definite evidences of typical rheumatic changes, and a few of these appear questionable.

An arterial disease resembling periarteritis nodosa has been found in lower animals, even in wild deer,²¹ further suggesting that it is a specific disease. To the present time the causative agent has not been determined either as a bacterium or as a filtrable virus, but the nature of the lesion suggests an infectious etiology.²²

There is no age incidence, the youngest patient being 3 months and the oldest 78 years of age. Fifty per cent of the cases occur between 20 and 40 years of age.¹⁰

SYMPTOMATOLOGY AND DIAGNOSIS

The symptoms are extremely varied, as would be expected, since the arterial system of any organ or set of organs may be involved, and even different organs in turn as the process subsides in one and becomes manifest in another, as occurred in case 1. The most outstanding clinical manifestations are those referable to the kidney. Heart failure with symptoms similar to the common clinical picture of coronary disease may appear as an isolated clinical manifestation.²³ On the picture may be one of peripheral neuritis, even including the cranial nerves.⁴ Involvement of the central nervous system occurs in only about 8 per cent of cases.¹⁰ This small percentage is remarkable, and when the central nervous system is involved it is prac-

tically always the brain.²⁵ Ophuls² was able to find only four cases of cerebral involvement in the seventy cases that he reviewed in 1923. Since then other cases of cerebral involvement have been recorded.²⁶ Skin lesions not infrequently occur, taking the form of subcutaneous hemorrhages, urticaria and in particular purpura resembling Schonlein's disease. At least one case of erythema nodosum has been reported as due to vascular changes in the skin.¹⁵ Gastro-intestinal symptoms with bloody diarrhea are frequent, and peritonitis may develop²⁷ from necrosis and perforation of the intestinal wall. Almost any symptom or set of symptoms may occur and may vary from time to time, causing a most confusing clinical picture. The general symptoms are fever, never very high, sweating, rapid pulse and muscular and abdominal pains even when there is no outstanding mesenteric involvement.

The particular character of the local symptoms depends on the system of arteries that happens to be involved. The frequent involvement of the kidney most often leads to a diagnosis of a primary medical or surgical renal lesion.²⁸ The most frequent diagnosis in the cases of outstanding renal involvement reviewed has been 'hemorrhagic nephritis' or an analogous designation.²⁹ Numerous deaths from renal hemorrhage have been reported.³⁰ Even unilateral involvement of the kidney with hemorrhage has occurred.³¹ Other such sharp localization of symptoms as those referable to the gallbladder leading to the removal of that organ³² has been reported. Occult hemorrhage and death may occur, as in the rupture of an aneurysm of the hepatic or cystic arteries.³³

The diagnosis has seldom been made during life, and then it has been more or less accidental.³⁴ This is not remarkable, considering the protean character of the manifestations and their ability to simulate almost any ordinary clinical entity.³⁵ The symptomatology is frequently vague, and there are no clinical diagnostic symptoms per se. The great difficulty in diagnosis is due to the variability of the clinical picture. Meyer³⁶ mentioned the combination of chlorosis, polyneuritis and gastro-intestinal symptoms as being a diagnostic

triad, to which combination was added nephritis by Brinkmann,³⁷ who suggested the diagnostic syndrome of polyneuritis polyserositis or a combination of the two, gastro-intestinal symptoms and nephritis. This syndrome is diagnostic if there is involvement of several systems of arteries simultaneously but when there is

Fig 1—Temporary mount of frozen section of artery showing typical changes. Permanent mounts of paraffin sections failed to include as typical a lesion and this preparation had deteriorated and faded greatly when photographed later, losing the distinctive appearance of the intense cellular infiltration and extensive perivascular changes.

localization of the process to one or two organs there is nothing in the symptoms referable to a disturbance of the organ or organs that in any way suggests the specific nature of the pathologic condition. In the end, the diagnosis depends on the typical pathologic changes found in the arteries either at biopsy or post mortem.

There are no clinical laboratory aids. Moderate or severe leukocytosis is present though not universally. Marked eosinophilia has occurred only a few times.³⁸ Ophuls² remarked on the absence of a marked eosinophilia in the circulating peripheral blood in the face of a decided eosinophilic infiltration in the lesions in his case.

PROGNOSIS AND TREATMENT

In the recognized cases, recovery has been rare. An occasional recovery has apparently occurred¹⁰ as in case 1. Since there is some tendency to remission and even apparent recovery in the severe and recognized

cases, it is possible that many mild cases exist and go on to spontaneous recovery unrecognized.

Except for general physiologic measures and antisyphilitic treatment and repeated blood transfusions, no other form of treatment has been used frequently, and the efficacy of these measures is questionable. Several of the patients who have apparently recovered have been given antisyphilitic treatment.

REPORT OF CASES

CASE 1—History—A white man aged 31, consulted Dr. John P. Henry in January 1934 for asthma of about five months duration. Because of other clinical features in the case, Dr. Henry referred him to me for diagnostic study. Except for the asthma, the patient noticed nothing unusual until about seven weeks previously, at which time a febrile illness developed. He had some fever for four or five days and thought it was a common cold. Early in this rather mild illness blood counts, made by his attending physician in another city, showed an essentially normal red cell count and hemoglobin but a leukocytosis of 16,400 with polymorphonuclear leukocytes 82 per cent, lymphocytes 11 per cent, large mononuclears 5 per cent and eosinophils 2 per cent. Five days later, after the patient became ambulatory, blood counts made in the office of Dr. G. Y. Gillespie in Greenwood, Miss., showed red blood cells 4,000,000, hemoglobin 75 per cent, leukocytes 17,600, polymorphonuclears 22 per cent, lymphocytes 13 per cent and eosinophils 65 per cent. A few days after this illness a pain developed in the neck and in about seventy-two hours all the muscles became painful and the patient began to have fever again. Shortly afterward localized pain appeared in the left ankle which was soon followed by swelling and the appearance of purplish red spots in the skin over the ankles. Within a day or two the right ankle underwent a similar change and

Fig 2—A small artery in subcutaneous tissue. The perivascular cellular changes are moderate in extent but distinctive.

this persisted to the time he came under my observation. At that time there were generalized weakness, soreness and pain in all skeletal muscles and much pain, stiffness and swelling in both ankles and feet.

Examination—The nose showed thickening and congestion of the mucous membrane and there was considerable obstruction by reason of mucous membrane changes. Examination of the teeth, mouth and throat generally was negative. The heart

³⁷ Brinkmann. Zur Klinik der Periarteritis nodosa. München med. Wchnschr. 69, 703 (May 12) 1922.

³⁸ Lewis C. Report of Case of Periarteritis Nodosa. Proc. Path. Soc. Philadelphia 14, 134, 1911. Pickert-Meike H. Ueber einen Fall von Periarteritis nodosa. Frankfurt Ztschr. f. Path. 23, 513, 1920.

and lungs were normal. The abdomen was entirely normal. Examination of the neuromuscular system and the eyegrounds was negative. Both ankles were edematous and the skin overlying them to a point about half-way up the leg showed rather thickly scattered erythematous purpuric-like lesions. On the outer aspect of the left ankle was a deeper ecchymotic area that appeared like an inflammatory process in the subcutaneous

Fig 3—Active lesion of vessel in subcutaneous tissue. Frozen section. An active lesion did not appear in portion of tissue from which permanent sections were made.

tissue. One or two nodules were felt beneath the skin on the outer aspect of the left leg above the ankle which were small and painful. The skin overlying these nodules showed slight redness. The muscles were tender throughout and motion was slow and painful. There were a few small shotty subcutaneous nodules over the upper extremities similar to those in the legs. The skin over which showed no reaction. There was generalized lymphatic enlargement, the nodes being painless with no skin reaction over them. The temperature was 98 F, the pulse 108 and the blood pressure 95 systolic 80 diastolic.

At first observation red blood cells numbered 3,710,000 with hemoglobin 11.3 Gm per hundred cubic centimeters of blood. White blood cells numbered 32,000 with polymorphonuclear leukocytes 28 per cent, eosinophils 67 per cent and lymphocytes 5 per cent. The blood Wassermann reaction was negative. The urine showed a heavy trace of albumin, a few hyaline casts, pus cells and red cells. Five specimens of feces were negative for parasites and ova. Three blood cultures on successive days were negative at the end of two weeks. The blood sugar was 133 mg per hundred cubic centimeters (not fasting). Total nonprotein nitrogen was 40 mg per hundred cubic centimeters. Uric acid was 4 mg. Subsequent observations showed an average of 23,000 leukocytes and an average of 66 per cent eosinophils. An electrocardiographic tracing showed evidences of myocardial changes suggesting coronary disease.

A piece of skin and subcutaneous tissue from the left leg was removed by Prof. J. L. McGehee for microscopic study. Sections of a small artery contained in the tissue showed intense inflammatory cellular infiltration of the adventitia extending through the media and involving the intima with obliteration of the lumen. The cellular infiltration extended well beyond the artery out into the perivascular tissue producing a definite

nodule. These cells consisted for the most part of polymorphonuclear leukocytes with many eosinophils and some round cells. The histologic picture presented by the artery was typical of periarteritis nodosa.

Clinical Course—The treatment consisted of general physiologic measures with repeated blood transfusions of an average of about 350 cc each, small doses of nearsphenamine, a high vitamin diet and general symptomatic measures. While the patient was under observation there appeared evidences of derangement of almost every system that is capable of producing clinical manifestations. At different times there were such manifestations as mild delirium, marked evidence of nephritis with blood nitrogen going as high as 100 mg per hundred cubic centimeters, symptoms of coronary disease, hemorrhagic retinitis, severe abdominal pain with bloody diarrhea, peripheral neuritis in the arms and legs, and cough with blood-streaked sputum. Some of these various manifestations coexisted and some appeared as others were disappearing. The patient began to improve and was discharged to his home and the care of his family physician, very much improved clinically. About the only pronounced symptoms at the time of discharge were a flaccid paralysis of the right leg and right arm and to a lesser extent of the left arm and marked general weakness.

The patient returned for observation about ten months later, Oct. 19, 1934, having gained about 40 pounds (18 Kg) and free from all symptoms except those of neurologic residuals as a result of acute peripheral neurologic involvement at the time of the acute illness. Examination was entirely negative except for atrophy of the intrinsic muscles of the hand and the right forearm and atrophy of the muscles of the right leg with toe drop. There were no sensory changes. The temperature was 98 F, the pulse 82 and the blood pressure 98 systolic 70 diastolic. The red blood cells numbered 5,200,000, with hemoglobin 15.7 Gm per hundred cubic centimeters. The leukocytes numbered 6,800, polymorphonuclear neutrophils 57 per cent and lymphocytes 43 per cent. Examination of the urine was negative. The sedimentation rate was normal. An electrocardiographic tracing was negative. The patient considered himself symptomatically well except for the neurologic changes.

Fig 4—Healed lesion of vessel in subcutaneous tissue. This vessel present in same block of tissue in which active lesion was found but in a different portion.

referred to and was attending to his work regularly. He has not been seen since that time but reports indicate that he is still well.

The important features of this case are (1) generalized involvement of somewhat migratory character, (2) marked eosinophilia of peripheral blood, (3) diagnosis during life, and (4) apparent recovery.

CASE 2—A white man, aged 35 noticed swelling of the left foot and leg to a point a little below the knee three months before he came under observation, together with the appearance of red nodules in the skin. Two similar nodules had been present on the dorsum of the right foot but had disappeared at the time he came under observation. The nodules were only slightly tender and the only subjective symptom was slight discomfort in the left foot. Physical examination was entirely negative except for the red subcutaneous nodules and slight pitting edema of the left foot and leg. Pulsation of arteries was present and apparently normal, and there were no trophic or color changes. Complete laboratory studies were negative in all respects except for a persistent leukocytosis averaging about 12 000 with an average of 75 per cent polymorphonuclear neutrophils and a trace of albumin in the urine. Tissue removed from the calf of the left leg showed a typical lesion of periarteritis of a small artery in a frozen section. A permanent section from the same block of tissue failed to show any active lesion but did show a healed lesion in a somewhat larger artery. In addition to antisyphilitic treatment roentgen therapy is being given by Dr W R Bethea of the Baptist Hospital and to date he has received 1746 roentgens over the feet and legs divided into three sances. At the time of this report he has been under observation about seven weeks and apparently is slowly recovering. No new lesions have appeared and the ones that were present have disappeared either completely or nearly so. No additional symptoms or changes in the result of laboratory examinations have appeared.

ELECTRICAL ALTERNANS

A CLINICAL STUDY WITH A REPORT OF TWO
NECROPSIES

WALTER W HAMBURGER MD
LOUIS N KATZ, MD
AND
OTTO SAPHIR MD
CHICAGO

It is generally recognized that electrocardiography adds little to the clinical diagnosis of pulsus alternans. While the electrocardiogram may show evidence of slight or widespread coronary and myocardial involvement paradoxically it rarely demonstrates alternation of the ventricular complexes as one, a priori, might expect.

The two cases of electrical alternans without pulsus alternans we are about to describe—the first to be reported in this country—are in sharp contrast to the usual type of alternans, which is confined to the pulse heart sounds or apex beat, without evidence of electrocardiographic alternation. The electrocardiographic finding of electrical alternans, judging from the literature and our own experience, is an exceedingly rare phenomenon. Our first case, observed in March 1933 constitutes the only one we have seen in a series of approximately 10 000 electrocardiograms covering a period of about thirteen years. However, since the appearance of the first case, three additional cases of electrical alternans in one or more leads of the electrocardiogram have come to our attention. One constitutes the second case of this report a second occurred during an attack of paroxysmal tachycardia and a third was associated with electrocardiographic evidence of bundle branch block. In none of the latter three cases were

simultaneous venous or arterial pulse tracings made to rule out pulsus alternans, so that it is remotely possible that one or more of them are, in reality, examples of pulsus alternans with alternation of certain electrocardiographic complexes. Such a combination is rare but not as unusual as isolated electrical alternans without apparent mechanical alternation. The appearance of these three additional cases shortly after the finding of our original case suggests that such cases may be easily overlooked unless attention is particularly directed to them. One must be, as it were, 'alternans conscious'.

REPORT OF CASES

CASE 1—Dr S a retired woman physician, aged 48, referred through the kindness of Dr Robert Sonnenschein, seen in March 1933 complained of mild pain in the left side of the chest radiating on occasion to the left shoulder and spine first noticed some six years before and recurring during the past four months. It appeared frequently while the patient was eating and doing her daily housework. She also complained of vertigo palpitation depression with occasional crying spells easy fatigability and moderate dyspnea. She had two nervous breakdowns which coincided with the two periods of precordial pains. Her family, past and personal histories other wise were essentially negative.

The patient was moderately obese. The pulse rate was 120 and the blood pressure 196 systolic, 100 diastolic. The left heart border was displaced outward slightly, her heart tones were 'tic-tac' in quality and she had a markedly accentuated aortic second sound and a faint systolic blow over this region. A coarse tremor of the fingers was present. The metabolic rate was +137 per cent. An electrocardiogram at this time showed besides a left axis deviation, a frank and continuous electrical alternans in leads 3 and 4. The alternans was a discordant one of the QRS and T waves.

The impression at this time was obesity, hypertension arterio sclerotic coronary heart disease moderate cardiac hypertrophy early mild congestive heart failure with anginal attacks sinus tachycardia anxiety neurosis and electrical alternans the last term being used for the first time in our cardiac diagnostic nomenclature. She was advised to secure more physical and mental rest and was placed on a preparation combining theobromine and phenobarbital.

She returned again about four weeks later feeling and appearing distinctly improved. The pulse rate was 100 and the blood pressure 166 systolic 90 diastolic. A second electrocardiogram (fig 1) was taken at this time and substantiated the earlier finding of discordant electrical alternans. In this record the alternation is present in all three leads and is a discordant one of QRS and T.

She was asked because of the unusual electrocardiogram to report to the heart station for further study. A week later the electrocardiogram was recorded simultaneously with optically recorded pulses from the subclavian artery radial artery and external jugular vein as well as with optically recorded apex beats and apical heart sounds (Wiggers method¹). No alternation of the pulse, apex beat or heart sounds was found while the electrical alternans was present proving this to be an instance of isolated electrical alternans.

The inconstancy of the alternation suggested to us the possibility that breathing might be related to the alternation as has been found to be the case in other instances.² Simultaneous records of the electrocardiogram optically recorded pulse and respiration were therefore made. As shown in figure 2 some but not all of the inspirations started transient electrical alternation of from one to three cycles. When the breath was held no alternation appeared. In several instances in these curves the alternation was accompanied by alternation in cycle length. No alternation of the pulse was found.

The patient disappeared from view until July 1934 a period of fourteen months. The electrocardiogram when she returned

for examination to our amazement showed complete absence of the alternans (fig 3 A). Her report and our examination showed her to be in a satisfactory state.

Five months later she entered the hospital because of failing strength and exacerbation of old symptoms following a 'cold' six weeks prior to entrance. Two weeks afterward an acute viselike pain suddenly developed over the precordium radiating to the left shoulder and elbow which had recurred repeatedly since. There had been increasing general nervousness and some emotional instability. Sedatives and glyceryl trinitrate gave her a good deal of temporary relief. On the day of admission she had had seven attacks of precordial pain by late afternoon.

Fig 1 (case 1)—Electrical alternation in all three standard leads involving R₁, R₂, T₁, T₂ and S₁, S₂; discordant alternation between R₁, R₂ and T₁, T₂. Record taken April 25 1933

Examination at this time revealed a rapid, regularly beating heart, with a rate of 120. The left border was outside the nipple line. The aortic second and the pulmonic second sounds were accentuated. There was gallop rhythm at the apex. The lungs were clear. There was slight edema along the tibial crests. The temperature was normal. Successive arterial blood pressure readings were 142/98, 124/80 and 102/70. A 2 meter roentgenogram revealed a moderate cardiac enlargement. The basal metabolism a week later, was +29.4 per cent. The urine showed no abnormalities, she had a moderate secondary anemia. During her stay in the hospital moisture developed at both lung bases posteriorly. Liver dullness increased and the pulse became more rapid. It was apparent a week after entrance that she was critically ill. She was placed on sedatives including morphine and a mixture of opium and alkaloids.

Several electrocardiograms were obtained at this time with difficulty and showed absence of the electrical alternans last observed nineteen months previously. The absence of electrical alternans is seen in the records in figure 3 B and C.

The marked change in the ST segment depression in leads 1 and 2 and elevation in lead 3 is evident in record C which is typical of other records taken during this time and bespeaks progressive coronary insufficiency. The increase in the size of the T wave and the appearance of an upright T₁ probably have the same significance. During an original attack (fig 3 B) the electrocardiogram showed that ST₁ and ST₂ became smaller in all leads and auricular extrasystoles appeared. A tablet of 1/400 gram (0.0006 Gm) of glyceryl trinitrate relieved the attack and restored the electrocardiogram to its preceding state (fig 3 C). No increased irritability of the carotid sinus reflex could be demonstrated clinically or electrocardiographically.

December 15 she became rapidly worse and before oxygen could be administered and in spite of the use of caffeine camphor and the like she died.

The necropsy revealed a moderate generalized arteriosclerosis with coronary arteriosclerosis. There was a recent bilateral bronchopneumonia. The lungs, liver, spleen and kidneys showed chronic passive hyperemia of long duration. The outstanding changes of the heart at autopsy were the small multiple recent and organizing infarcts and areas of fibrosis. The coronary

arteries themselves showed only a moderate amount of arteriosclerotic change. There was an atypical distribution of the coronary arteries the right taking care of the nutrition of the largest part of the heart (fig 4). There was an arteriosclerosis of the ascending aorta arteriosclerotic plaques which were present just above the mouth of the right coronary artery caused a marked narrowing of its orifice. The left coronary artery was much less in extent than normal and was patent. It is likely that the changes at the mouth of the right coronary artery, which supplied most of the heart muscle fibers were responsible for the myocardial fibrosis. Because of the myocardial fibrosis, the heart probably became insufficient on various occasions. This insufficiency combined with the consequent temporary lowering of the arterial blood pressure on the one hand and the narrowing of the mouth of the right artery on the other, apparently was the principal factor in the causation of the multiple infarcts of the heart. Electrical alternans is not mentioned in the previous reports of multiple small or microscopic infarcts of the heart by Kirch³ and Buchner.⁴

CASE 2—Mrs L, aged 59 a patient of Dr Solomon Strouse's when first seen April 3 1934 had no complaints referable to the heart but complained of loss of appetite. On physical examination, the left heart border was found displaced outward. The urine contained albumin and hyaline and granular casts. There was slight edema of the legs. She was sent to the hospital, where definite signs of effusion of the right pleural cavity and considerable enlargement of the heart were found and verified by roentgen examination. The x-ray report indicated pericardial effusion but the clinical signs were not conclusive. The temperature was 99.2 F pulse 108 respiration rate 28 blood pressure 120 systolic 74 diastolic. The red blood count was 4,180,000, white count 12,150. There were rales and dullness over the right lung base. She became dyspneic and orthopneic. An electrocardiogram taken April 6, the day of admission showed an alternans of the QRS complex in leads 1, 3 and 4 without any alternans of the other waves (fig 5 4). Because of the patient's condition no opportunity was available for taking other types of records to rule out mechanical alternans. Thoracentesis yielded a bloody fluid in which tumor cells were found later. The roentgenograms taken after the chest had been tapped showed a consolidated area in the right lung in the lower portion of the middle third that was suggestive but not particularly typical of a malignant growth. The course in the hospital was steadily downhill and the patient died eight days after admission.

The clinical impression was that there was generalized arteriosclerosis with myocardial fibrosis, pleural effusion, and

Fig 2 (case 1)—Simultaneous continuous electrocardiogram (lead 2) and radial pulse and respiration curve. In the top strip brief periods of electrical alternation of 1 to 3 cycle duration may be seen apparently related to inspiration. Record taken May 1 1933

a possible malignant condition (location of the primary tumor could not be determined) with metastases into the pleura and the heart.

The necropsy revealed a primary carcinoma of a tertiary bronchus with extension into the lung and metastases to the pleura, mediastinal nodes pericardium innominate bones the second third and fourth lumbar vertebra and the urinary bladder.

Microscopically many small carcinomatous metastases were found throughout the myocardium.

LITERATURE

Pezzi⁵ in 1922, Chini⁶ in 1927 Galata⁷ in 1928 and Condorelli⁸ in 1929 were the first Italian writers to call attention to electrical alternans. Isolated electrical alternans was first described by the English investigator Mines⁹ in 1913 in the electrograms obtained from the

Fig. 3 (case 1)—A July 13, 1934 showing absence of alternans. B December 4 effect of an anginal seizure with blood pressure 145 systolic 100 diastolic. C ten minutes later relief due to glyceryl trinitrate with blood pressure 130 systolic 75 diastolic. Patient died December 13.

frog's heart. A very complete and critical summary and discussion of the literature up to 1930 may be found in the French monograph by Poumaillou¹⁰ on pulsus alternans. Poumaillou concluded that there are two forms of electrical alternans having different significance: (1) alternation of the T wave or without alternation of QRS which has the same significance as mechanical alternation and (2) alternation of the QRS complex or any of its components which is transient and totally unrelated to mechanical alternation.

Bruno Kisch¹¹ considers cardiac alternation in the same terms as Mines and Hering, namely that it is an expression of the mechanical behavior of the ventricles. He believes that all types of alternans are simply expressions of a basic alternans of the heart ('herz

Marked narrowing of mouth of the right Coronary Artery by Calcified plaque

Fig. 4 (case 1)—Sketch of the heart showing the atypical distribution of the coronary arteries and the location of the lesions found within the coronary arteries.

alternans"). This phenomenon may in various instances be demonstrated best by the electrocardiogram by the pulse curve or by other methods of examination. Kisch points out that electrical alternans may

consist of variations in either the amplitude (height), contour (form), direction or duration of the involved complexes. The most frequent forms are those involving T alone or both the QRS and T waves. Hering¹¹ in 1910, working on the mammalian heart, believed that alternation of QRS was an expression of alternation of the papillary muscles. Condorelli⁸ attributed the phenomenon to alternation in the conduction pathways. Condorelli¹² agrees with Kisch that clinical as well as experimental alternans is clearly an expression of exhaustion of the myocardium. He also agrees that electrical alternation probably has the same significance as regards prognosis as alternation of the contractile strength of the heart.

The literature contains many references to so-called coronary alternans, both experimental and clinical. Lewis¹³ in 1910 was among the first to demonstrate alternans of the heart following coronary occlusion. Condorelli¹² described electrical and pulsus alternans in man following disturbances in coronary function and also reported isolated electrical alternation in the dog's heart following coronary occlusion. Kisch found that interference with the nutrition of the dog's heart through coronary closure may cause alternation even in the absence of an increase in heart rate, an alternation most marked in that portion of the ventricles in

Fig. 5 (case 2)—A electrical alternation in leads I, II, and III involving only the QRS deflections. Records obtained April 6, 1934 eight days before death. B record of alternation in auriculoventricular conduction (PR intervals) accompanied by concordant alternation in the PP interval and discordant alternation in the RR interval observed in a patient diagnosed clinically as having a recent coronary occlusion and enlargement of the large bowel. The electrocardiogram is typical of a recent coronary occlusion with myocardial infarction.

which the most serious nutritional impairment exists. The alternation promptly disappears following removal of the coronary ligatures.

COMMENT

The electrocardiogram in our first case falls into the first of Kisch's² etiologic types, namely, the so-called coronary alternans. The transitory character of the electrical alternans which is so unlike pulsus alternans may account for the rarity of observed and recorded cases. It is a phenomenon that should be carefully looked for even when mechanical alternans is not demonstrable.

The electrical alternans in case 2 is, in view of the autopsy, also attributable to coronary insufficiency in this instance resulting from the multiple tumor emboli obstructing the blood flow. Although no mention is made of the clinical presence of pulsus alternans in the second case, we cannot be certain that this is not an instance of electrical alternans with mechanical alter-

nans rather than isolated electrical alternans. In this instance, in contrast to the first case, the electrical alternans was observed accidentally in the last weeks of the patient's life.

It is possible from the nature of the anatomic lesions in these two cases that electrical alternans may ensue more readily in the presence of widely disseminated small coronary occlusions and multiple minute myocardial dissolutions than from more extensive isolated lesions. If this is so, its demonstration will be useful in the type of alternans arising on a coronary insufficiency basis.

The relation of the electrical alternans in case 1 to respiration seems established from our records. The precipitating factor in all likelihood is a reflex from the lungs to the heart impairing the conduction of the impulse within the ventricles. It is possible, but less likely, that the mechanism is some respiratory disturbance of the cardiac dynamics.

There is sufficient evidence in the literature and in our first case to show that the electrical and the mechanical alternation appear clinically independently of each other and consequently by experience might be found to have different clinical significance, as Poumailloux states. The absence of one form of alternans does not rule out the presence of the other. This is of great practical significance, since the examiner should not be satisfied merely to determine the presence or absence of pulsus alternans but also should look for the presence of alternation in the veins, the apex beat, the heart sounds and the electrocardiogram.

The primary disturbance in all types of alternans is alternation in the physiologic response of parts of the heart. It is very easy to conceive of a distribution of alternating fractions in the heart such that the mechanical summation makes the alternans practically nonapparent with the methods available for recording mechanical events, while the electrical balance is favorable for a marked electrical alternans. The converse situation is also easy to appreciate, namely a manifest mechanical alternans with neutralization of the electrical stresses such that the electrical alternans is not apparent. Since the distribution of the alternating parts of the heart is the factor determining the form the alternans will assume, more attention, it seems to us, should be paid to the thorough examination of the patient to rule out completely the presence of alternans of any type.

A typical example of the effect of location of the alternating fractions in the conduction system is shown in figure 5B. This is an unusual electrocardiogram in which the alternation consists of alternation of auriculoventricular conduction without any alternation of the various electrocardiographic complexes. This peculiar alternation is associated with a concordant alternation of the PP intervals and a discordant alternation of the RR intervals. The only previous report we have seen is one by Carter and Faulkner¹⁴ in which the alternation in auriculoventricular conduction occurred in the turtle heart. The patient from whom this unusual electrocardiogram was made a private patient of Dr Nathan Cohn had a carcinoma of the large bowel and a recent coronary occlusion developed a few days before the electrocardiogram was taken. He had also been given digitalis. The electrocardiogram is typical of recent coronary occlusion and shows sinus rhythm, first degree auriculoventricular block and left ventricular preponderance in addition to the peculiar type of alter-

nation. The P wave is buried in the T wave but its position varies alternately. This is due partly to the alternation of the PR interval and partly to the alternation of the PP interval.

The possibility of different prognostic significance of the various types of alternans should for the present be held *sub judice*. In arriving at a prognosis one should pay attention rather to other circumstances accompanying the alternans, such as the heart rate, the presence of extrasystoles and the clinical state of the patient. The occurrence of electrical alternans in paroxysmal tachycardia is not at all uncommon and is of no serious moment. When electrical alternans occurs at slower heart rates, however, as in the two cases examined post mortem, it should be viewed with grave concern, a finding stressed by Chinn.⁶

The transitory nature of electrical alternans in our first case might be attributed to improvement of the heart, but it is just as likely, if not more likely, that its disappearance has exactly the opposite significance, namely, that the condition of the heart has become worse. Alternans implies that at a certain stage of the heart's weakness certain regions are unable to respond normally to every stimulus but fluctuate alternately between a better and poorer response—or even no response. As the condition of the heart progresses downward the condition is changed and the heart may give a poor but constant response to every stimulus.

SUMMARY

1 In a case of transient isolated electrical alternans autopsy revealed an anomalous distribution of the right coronary artery with a calcified plaque markedly narrowing its mouth generalized coronary arteriosclerosis and multiple microscopic myocardial infarcts. In a second case of possible isolated electrical alternans autopsy revealed multiple minute carcinomatous metastases within the myocardium and in the blood vessels of the heart. In the instance of alternans in auriculoventricular conduction no similar clinical report was found in the literature.

2 It seems likely that the anatomic lesions in the first two instances, by leading to malnourishment of fractions of the heart, were responsible for the electrical alternans. They are therefore both of the coronary type of Kisch. The appearance of electrical alternans in instances in which the myocardial lesions are small and scattered may be significant.

3 A search of the literature revealed the rarity of isolated electrical alternans, our first case being the first described in this country and the first published with necropsy data.

4 The transitory nature of electrical alternans is demonstrated in our first case.

5 There is a grave prognostic significance of electrical alternans.

6 While alternans of the heart may appear in several forms there is evidence to show that fundamentally the mechanism is identical in all instances, namely, alternation of activity of portions of the heart. The form taken by the alternans will depend on the distribution of the alternating portions of the heart.

7 The transient character of electrical alternans emphasizes the need for closer scrutiny of electrocardiograms. The gravity of alternans and the fact that it sometimes appears only in the electrical form emphasizes the need of becoming more "alternans conscious." If more attention were paid to electrical alternans, probably many more instances would be found.

A METHOD OF ROENTGEN DIAGNOSIS OF NONOPAQUE FOREIGN BODIES IN THE ESOPHAGUS

WENDELL G. SCOTT, M.D.

AND
SHERWOOD MOORE, M.D.
ST. LOUIS

The detection and demonstration of nonopaque foreign bodies in the esophagus is a frequent and treacherous problem in roentgenology. By far the most common offender is a small piece of bone from a fowl or fish. These bones, which are usually from young animals and are consequently incompletely ossified and calcified and in which the calcium content has been further reduced by cooking, are relatively nonopaque to x-rays. The bone most frequently encountered, according to the Jacksons¹ and in our experience, is a fragment of the sternum of a chicken. A piece of rib is next in order.

Another type of radiolucent foreign body is buttons, many of which are transparent to roentgen rays and require the aid of a barium mixture for their visualization. A firm bolus of food, especially meat, is a third type of radioparent foreign body when halted in its passage by inherent or adjacent lesions of the esophagus, e.g., mediastinal tumors, aneurysms, carcinomas or strictures of the esophagus, enlargements of the thymus or thyroid, or an enlarged left auricle. This type of foreign body as a rule is readily identified with the use of an opaque meal because it produces a complete esophageal obstruction and the existence of offending lesions can be easily recognized.

The customary site of lodgment² of esophageal foreign bodies is at the level of the suprasternal notch, as it is normally the narrowest segment of the esophagus.³ Lesser constrictions occur at the introitus, at the level of the crossing of the left bronchus and at the diaphragmatic pinchcock. These levels must be kept in mind, as opaque mixtures may lag in traversing them and lead to an erroneous diagnosis.

The symptoms produced by nonopaque esophageal foreign bodies are in no wise different from those which are opaque. Patients who have swallowed a foreign body give a history of an initial choking. They are excited and apprehensive and complain of a persistent gagging or "obstructive" sensation. Dysphagia and odynophagia are cardinal symptoms. The movements of swallowing are exaggerated, and drooling is occasionally present. These patients rightfully regard the condition as an emergency.

Small jagged pieces of bone lodge because their sharp edges become partly embedded in the walls of the esophagus and the chance of producing a complete penetration with its consequent mediastinitis is always imminent. It was with the idea of minimizing this risk that the radiographic and roentgenographic technic to be described was developed.

Before the examination, all clothing must be removed. The films and fluoroscopic studies must include the nasopharynx and the stomach. Only films technically perfect are acceptable and quick exposures (from one-

fifteenth to one-twentieth second) are absolutely necessary for the elimination of blurred shadows resulting from movement.

Anteroposterior and lateral views of the neck are the first films made with the hope of visualizing the suspected fragment before resorting to the use of opaque mediums. The lateral exposure (fig. 1) is more helpful as the hypopharynx is not obscured by the overlying cervical spine. Chamberlain and Barton⁴ warn against mistaking areas of ossification in normal laryngeal cartilages for foreign bodies and emphasize the importance of accurately identifying them.

If the preliminary films do not demonstrate the object, the patient is placed before the fluoroscope and given a thick suspension of barium sulfate in water and carefully observed to determine whether there is a deviation or division of the stream or a filling defect of the esophagus. After several swallows of the opaque

Fig. 1 (case 1).—Lateral scout film of neck demonstrating a fragment of chicken rib in the esophagus at the level of the suprasternal notch.

mixture, the esophagus is carefully searched for residual flecks of barium that might be clinging to the foreign body. Even if the diagnosis of a radiolucent foreign body is established, we feel that at least one film of the entire esophagus should be made if only to serve as a matter of record. When the evidence is inconclusive, roentgenograms are absolutely essential because of their greater contrast and detail.

We have obtained the best results by using a very thin watery solution of barium—so thin that the esophagus when filled is not completely opaque. The patient holds a glass of this mixture in his left hand while standing in front of the regular cassette changer and is instructed to drink the solution through a glass tube in small, rapid swallows in an effort to maintain a continuous stream down the esophagus. Exposures are made in both the anteroposterior and the right anterior oblique position, which is preferred to a lateral view, as the region of the suprasternal notch is better visualized. This barium mixture coats the esophageal walls as iodized oil does the bronchi, and on meeting a foreign

From the Edward Mallinckrodt Institute of Radiology, Washington University School of Medicine.

⁴ Chamberlain, W. E. and Young, B. R. *Ossification (So Called Calcification) of Normal Laryngeal Cartilages Mistaken for Foreign Body*. *Am. J. Roentgenol.* 33: 441-450 (April) 1935.

body it produces a constant filling defect. In addition, it coats the object, which is then demonstrated as a constant collection of opaque material within the lumen of the esophagus. It should be emphasized that both the filling defect and the mass of barium in the lumen coinciding with it must be present in both views or in subsequent films. The following cases demonstrate the technique and show the foreign bodies.

CASE 1 (fig 1, kindness of Dr J B Costen)—A white woman, aged 44, a housewife, entered Barnes Hospital Aug 21 1926 with a history of "choking" on a chicken bone. The preliminary films established the diagnosis. Esophagoscopy was performed and the partially embedded fragment was removed on the second attempt.

CASE 2 (fig 2, kindness of Dr M F Arbuckle)—A white woman, aged 39, a housewife, entered Barnes Hospital March 4 1935, with the history of having swallowed a chicken bone several hours previously. Scout films failed to show the foreign body. Roentgenograms made during the swallowing of a thin barium sulfate solution localized the fragment, which was then removed at esophagoscopy. A large mass of meat was clinging to the bone.

CASE 3 (fig 3)—A white man, aged 42 married, a salesman entered the hospital Dec 12 1934 complaining of dysphagia and odynophagia with the history of having swallowed a chicken bone three days previously. It was demonstrated by

Fig 2 (case 2)—The anteroposterior film of the esophagus shows a persistent filling defect of the wall and a constant mass of barium in the lumen. Note how the barium coats the mucosa without producing complete opacity of the tube. (Also see figure 3.)

the use of thin barium sulfate. The fragment was not seen in the preliminary films. At esophagoscopy Dr M F Arbuckle found and removed a piece of chicken rib at the predetermined site.

We have abandoned the practice of having patients swallow bariumized biscuits, plidgets of cotton saturated with barium sulfate, or capsules filled with

bismuth subcarbonate^{2b} because the weight of these substances on a sharp foreign body, aided by prolonged esophageal peristalsis, may produce a complete penetration. The fact that such opaque solids move slowly and may even stop in their passage through the lower part of the esophagus makes them unreliable agents in exploring this segment. Incidentally, we feel that an effort should be made to discourage the common

Fig 3 (case 3)—A right anterior oblique view of the esophagus during the swallowing of a thin barium solution. The foreign body is visualized as a persistent mass of barium within the lumen coinciding with a constant filling defect.

practice of patients forcefully swallowing a large firm bolus of food in an effort to dislodge a jagged intruder, as not only does it increase the danger of perforating the esophagus but the presence of residual food obscures the foreign body and becomes a hindrance to esophagoscopy. While reviewing the literature, we inadvertently found several case reports⁶ in which small nonopaque bones perforated the esophagus and produced severe infections.

As foreign bodies are prone to shift and change positions, esophagoscopy should be performed as soon as possible after the diagnosis has been established. Furthermore, as pointed out by all writers in this field, esophagoscopy is indicated in spite of a negative roentgenoscopic and radiographic examination if the patient's history and symptoms point to a foreign substance.

SUMMARY

1. A routine free from the risks of methods employing solid or semisolid opaque mediums is desirable in diagnosing nonopaque foreign bodies in the esophagus.

6. Pincoast H K. Roentgenology of the Pharynx and Upper Esophagus. *Am J Cancer* 17: 373-395 (Feb.) 1933 (chicken bone). Siltstein H C. Duck Bone Impacted in Lower End of Esophagus. Erosion of Oesophageal Wall. Fatal Haemorrhage. *Ann Surg* 95: 794-797 (May) 1932. Ginsburg Louis. Perforation of the Esophagus by a Chicken Bone. *Ohio State M J* 27: 568-570 (July) 1931. Iglauder Samuel and Ransohoff J L. Perforation of the Esophagus by a Foreign Body (Rabbit Bone) with Report of a Case. *Preventing Unusual X-Ray Signs*. *Laryngoscope* 34: 821-825 1924.

5. Wilson W F. Oesophago-copv. A Means of Detecting Foreign Bodies Non Opaque to X Rays. *Brit M J* 1: 656 (April 4) 1925.

2 The routine consists of first taking anteroposterior and lateral "scout" films of the neck in the hope of visualizing the object second, if these are negative the patient is observed by the fluoroscope while swallowing a very thick barium mixture and any delay, filling defect deviation or division of the column is noted, third, anteroposterior and oblique roentgenograms are made during the rapid swallowing of a thin barium sulfate solution The presence of a constant filling defect and a persistent mass of barium in the lumen constitutes sufficient evidence for the diagnosis of a nonopaque foreign body

3 Rapid exposures (from one-fifteenth to one-twentieth second) and technically perfect films are necessary

4 As foreign bodies are prone to shift esophagoscropy should be done as soon as the diagnosis is established

5 Esophagoscopy is indicated even with a negative roentgenoscopic and radiographic examination if the patient's symptoms are those of a foreign body

6 Propaganda should be disseminated among the public as a warning of the danger of completely perforating the esophagus by forcefully swallowing a large bolus of food in an effort to dislodge a sharp foreign body

HEREDITARY ECTODERMAL DYSPLASIA OF THE "ANHYDROTIC TYPE"

WITH SYMPTOMS OF ADRENAL MEDULLA INSUFFICIENCY AND WITH ABNORMALITIES OF
THE BONES OF THE SKULL

S. J. THANNHAUSER, M.D.
BOSTON

In 1838 Widderburn reported a very striking anomaly of the skin which he observed in ten males of a Hindu family. The symptomatic triad of this anomaly consisted of complete inability to sweat (anhidrosis), deficiency of the scalp axillary and pubic hair (hypotrichosis) and partial absence or an incomplete development of the teeth (anodontia). In recent years Thadani has reported similar cases occurring in Hindu families from a district where inbreeding is common.

Among Europeans Thunman in 1848, Williams in 1848, Guilford in 1883 and Hutchinson in 1886 described similar hereditary ectodermal anomalies. Guilford in 1883 reported the existence in his patient of a saddle nose and established the fact that the afflicted members of the patient's family had the same deformity of the nose. Hutchinson observed a defect on the mamilla, a finding that is not present in all cases. In the German literature Tendlaw in 1902, Weichselmann and Loewy in 1911 and Crist in 1913 described families with this congenital disease. In these cases attention was called to a decrease of intellect and a deformity of the auricles (satyr auricles). In recent years several other cases have been reported in the American and German literature and the name hereditary ectodermal dysplasia of the anhydrotic type has been adopted for this hereditary disease. In reports in the American literature there are cases which exhibit only the dystrophy of the hair and nails without changes in the sweat or sebaceous glands or in the skull contours (McKay and Davidson). Transmission by both

sexes is manifest in these cases of McKay and Davidson. Gordon and Jamieson¹ justifiably differentiate a group only with dystrophies of the hair and nails from the ectodermal dysplasia of the "anhydrotic type." Clouston reported 119 cases in six generations with dystrophy of the nails and hair. Some of this family exhibited only keratoderma plantaris et palmaris. Clouston believed that these were due to residual forms of an ectodermal dysplasia of the anhydrotic type. It may be that one or the other of the manifestations of the hereditary ectodermal dysplasia may be observed occasionally as *formes frustes*. Perhaps the hereditary alopecia belongs to this group of hereditary dysplasia. It is evident that there is some relationship between all these features of hereditary ectodermal dysplasia, but

Fig. 1—Front and side view of patient

it is desirable to differentiate two main clinical syndromes, one consists of the symptomatic triad of anhidrosis hypotrichosis and anodontia and the other dystrophies of the hair and nails. The first group is transmitted by females and appears for the most part in males; the second may be transmitted by either sex and appears in both men and women. Siemens, utilizing the pedigree of Weichselmann demonstrated that the transmission of hereditary ectodermal dysplasia of the anhydrotic type is recessive and obligatory to sex. The same type of transmission is known to exist in hemophilic families. It must be mentioned here that Guilford in 1883, Gauermann in 1920 and Gordon and Jamieson in 1932 reported cases of women afflicted with hereditary ectodermal dysplasia of the anhydrotic type so that exceptions from the rule of transmission are still to be explained.

Following are the history and clinical observations in a case of hereditary ectodermal dysplasia of the anhydrotic type. They are remarkable in four points: 1 The patient has a pedigree confirming the fact that transmission is recessive and obligatory to sex. 2 The patient did not perspire until his sixteenth year. Subsequently he began to sweat but up to the present time sweating has occurred scantily and infrequently. 3 The patient exhibits signs of insufficiency of the adrenal medulla (the adrenal medulla is an ectodermal organ). 4 The roentgenograms of the skull show a deformity

of the bone typical of exostoses of the inner table of the skull a hitherto undescribed feature of hereditary ectodermal dysplasia of the anhydrotic type

REPORT OF CASE

History—H K, a man aged 23 a German complained of weariness in the late afternoon, weakness of the lower limbs and very often toward evening a slight rise in temperature (from 37.5 to 37.7 C., or 99.5 to 99.8 F.) which prevented him from working

Even as a child his hair was quite sparse. At the age of 17 he lost his hair entirely and a lanugo-like fine hair began to grow in its place. He stated that the axillary and pubic hairs never developed completely. Only a few short brittle hairs were noted in the axillae and over the pubes. The first teeth developed incompletely. From the history it was learned that there had never been complete development of the deciduous teeth. In fact the incisors never appeared. Before his sixteenth year he had never perspired. As a boy, physical exertion produced no moisture of the skin only palpitation. He was unable to play with other children during the summer months as he became exhausted rapidly. Since the age of 16 he had begun to perspire but the sweating which came on chiefly after exertion was slight inconstant and in his opinion insufficient. At the time of examination he felt very uncomfortable and was unable to continue his work during hot weather. Weakness in the legs shortness of breath and slight tremor of the extremities followed even relatively slight exertion.

Examination—He was 182 cm. in height and weighed 70 Kg. The skull was enlarged in circumference (61 cm.). The forehead was abnormally high and vaulted. The bones of the face were small. The outlines of the head resembled a hydrocephalus. There were only a few fine lanugo-like hairs scattered over the

Fig 2—Side view of skull

scalp and a few scant short hairs were observed in place of the eyebrows. There was a lack of secondary sex hairs only a small number of short, dry hair stumps were seen in the axillae and mons veneris. No hairs were present on the forearms or legs. The root of the nose was sunken the forehead bulged over the root of the nose. The peculiar shape of the

2 He complained of the symptoms very frequently to his physician but the only objective finding was a slight rise in temperature when he felt exhausted. The physician suggested an endocrine disturbance.

nose has been described as a saddle nose in the literature. A saddle nose is formed by a defect of the nasal bones especially the median bone. The outline of the nose in this disease however does not result from a defect in the nasal bones but is due to an abnormal prominence of the forehead. The lips were negroid. The outlines of the skull nose and lips are similar in all cases in which photographs are published. In

Fig 3—Front view of skull

fact all these patients resemble one another so closely that they might be members of the same family. The front teeth of the upper and lower jaw were artificial. Roentgen examination showed atrophy of the middle parts of the jaws and confirmed the reports of the patient that the greatest number of the anterior teeth had never developed. Both tonsils were present. There was no secretion from the nose or pharynx.

Fig 4—Family tree of patient

The ozena mentioned in most of these individuals was not observed in this patient. The sinuses were abnormally small in the roentgenogram. The skin was dry and smooth almost feminine in character. Pigmented areas were noticed in the back and on the abdomen. The color of the pigmented areas was brownish gray and cloasma like. There was no hyperkeratosis. The thyroid was normal in size. No glands were palpated in the neck axillae or groin. The thorax was normally developed. Clinical and roentgen examinations of the lungs were normal. The heart was normal in size being 8 cm. to the left of the midline and 4 cm. to the right. There were no murmurs. The rhythm was normal. The blood pressure was 90 mm. of mercury systolic and 60 diastolic. The liver and spleen were not enlarged. The sex functions were normal. Knee and ankle tendon reflexes were normal. The Babinski reflex was negative. The daily oscillation in temperature was

usually greater than 1 degree centigrade from 36.2 to 37.5 C or 97.1 to 99.5 rectal. After exercise the temperature rose above 38 C (100.4 F).

The formation of the cranium resembled somewhat the shape of an ocephalic skull. The sutures however were all present including a persistent frontal suture. There was marked bony overgrowth of the sinus table which formed edges projecting into the cranial cavity (general exostosis of the inner table). In contrast to the large cranium the facial bones were underdeveloped particularly the mandible and the maxilla. All the sinuses were small. The medial and lateral incisors in both jaws were absent or incompletely developed.

Urinalysis was negative for albumin, sugar and urobilinogen. The sediment contained some leukocytes. Blood examination revealed hemoglobin 95 per cent, erythrocytes 5,200,000 per cubic millimeter, leukocytes 5,800 per cubic millimeter, polymorphonuclears 57 per cent, band forms 3 per cent, lymphocytes 37 per cent, monocytes 3 per cent. Fasting blood sugar was 70 mg per hundred cubic centimeters. The sugar tolerance curve after the ingestion of 100 Gm of dextrose was 72 mg fasting, 107 mg in one hour, 130 mg in two hours and 82 mg in four hours. The basal metabolic rate was $+16\frac{1}{2}$.

COMMENT

Anhidrosis—The patient was unable to sweat before the age of 16. He then would sweat very slightly following activity. However, weariness, quivering of the lower extremities and slight elevation of temperature still occurred toward evening. In the previously described cases the absence of the sweat glands was a permanent feature. In this patient sweating occurred at the age of puberty but so inadequately that only a small amount of perspiration was produced. The temperature rise following exertion and warm baths has been described in those cases in which observations of the temperature have been made. It is probable that this symptom occurs in all cases of hereditary ectodermal dysplasia of the anhydrotic type. The slight rise of the metabolic rate is doubtless caused by the fact that the body is unable to perform its physical regulation of heat because of the absence or incomplete development of the sweat glands. Woodjatt at the latest meeting of the American College of Physicians pointed out that symptoms of masked hyperthyroidism (slight temperature rise, fatigue and tremor) may occur in patients with ichthyosis universalis as a result of their inability to perspire adequately.

Genealogy—The pedigree of the patient demonstrates inheritance of recessive characteristics obligatory to sex. The description of rare cases of hereditary ectodermal dysplasia of the anhydrotic type in females indicates that exceptions to this rule of inheritance may occur.

Adrenal Medulla—The patient presented signs strikingly suggestive of insufficiency of the adrenal medulla, to wit, low fasting blood sugar, flat sugar tolerance curve, scattered pigmentation of the skin (not mucous membranes) and low blood pressure. Embryologically the adrenal medulla is of ectodermal origin. It seems in this case that the adrenal medulla may also be involved in the hereditary ectodermal dysplasia of the anhydrotic type.

Abnormality of the Skull—Roentgenograms of the skull present a striking deformity with exostosis of the inner table. The skull however is not of ectodermal origin but is developed from the mesoderm. Although roentgenograms of the skull in previous cases are not available it is probable that all cases of hereditary ectodermal dysplasia of the anhydrotic type show this characteristic deformity of the cranial bones since all

the published photographs exhibited great similarity of contour. The resemblance is so striking that, as I have stated before, these patients seem to be members of the same family. Furthermore, the constant deformity of the nose, which has been erroneously termed saddle nose by previous investigators, is evidently not a defect of the nasal bone but rather a bulging of the frontal prominence and a depression of the base of the nose resulting from a narrowing of the sinuses.

POLYPOSIS OF THE COLON

REPORT OF A CASE

GEORGE E. W. HARDY, MD

TAMPA, FLA.

Despite the relative infrequency of its occurrence, a developing knowledge of polyposis of the colon has stimulated increasing interest in this disease. As early as 1721, Menzel¹ reported a case in which there was a general inflammation of the intestinal tract with a number of wartlike excrescences in the colon. In 1861 Luschka² described a colon containing thousands of polyps from the ileocecal valve to the anus, varying in size from a hempseed to a bean. Cripps³ in 1882 observed three cases occurring in the same family. The more recent literature on this subject bears such well known names as those of Murphy,⁴ Lockhart-Mummery,⁵ Erdmann,⁶ Morris,⁴ Gant,⁵ Soper,⁶ Doering and Coffey.⁷

For purposes of standardization, Erdmann⁴ suggested that the term "polyposis of the colon" be limited to designate an adenomatous hyperplasia of the intestinal mucous membrane as opposed to those polypoid tumors of the intestine which are histologically fibromas, myomas, lipomas and angiomas. The disease appears to be a uniform, nonspecific reaction of a preternaturally sensitive mucous membrane to a chronic irritant, a reaction which is variable only in degree. It is manifested grossly as scattered intraluminal tumors varying in size from a split pea to a grapefruit and has a specific predilection for the large intestine and the rectum. This predilection increases in direct proportion to distance from the ileocecal valve.

The simplest classification of this disease is that of Erdmann and Morris,⁴ which divides it into the adolescent and adult types. The adolescent or congenital disseminated type manifests itself in early youth is characterized by chronic recurring attacks of intestinal hemorrhage and diarrhea, and shows a tendency to occur in members of the same family. The adult or acquired type first appears in adult life in association with frank evidences of chronic traumatic and inflammatory lesions, to which it is evidently secondary. The two types have in common a marked predilection for the large intestine, an incidence of malignancy of more than 40 per cent and a tendency to chronic intestinal hemorrhage and diarrhea. They are dissimilar in that in the

adolescent type the polyps appear in almost countless numbers, are widely disseminated and show no gross evidence of a causative lesion, while in the adult type they occur in limited numbers and extent and almost invariably are associated with gross evidence of trauma inflammation or foreign body. The one is essentially a disease of early life, the other of middle or late life, occurring as the cumulative result of prolonged irritation incident to years of functional activity of the intestine. Woodward⁹ proposed a third grouping, characterized by the formation of polyps arising from islands of mucous membrane isolated in the bases of dysenteric ulcers and designated as "pseudopolyposis of the colon."

Graham¹⁰ stated that the diagnosis of the adolescent or congenital type may be definitely established or rejected by sigmoidoscopy, as in this form of the disease the polyps extend down to the anus. Erdmann,⁴ however, noted an occasional exception to this usual observation.

In 1928 Hullsiek¹¹ reported a study of all cases of the adolescent type of polyposis of the colon appearing in the literature and added one case that came under his observation, making a total of 127 cases. Since all cases listed as multiple polyposis of the colon were included, it is probable that at least a number did not belong to the congenital type, but some that were given in sufficient detail to mark them as obviously belonging to the acquired type were excluded. In this series, 66 per cent occurred between the ages of 15 and 35, 53 per cent occurred in men and 47 per cent in women, malignant disease was known to be present in forty-two cases, and in thirty-one other cases in which the presence of a malignant condition remained in doubt the patients died rather early of cachexia, inanition or bleeding. It is only fair to assume that the index of malignancy is actually higher than the figures represent. Mummers¹² stated that "almost all cases of multiple polyps of the colon eventually become malignant." The high incidence of malignancy is a factor of primary importance, which must be considered in the treatment of this disease.

Therapy naturally falls into two classes, palliative and radical. Because of the serious danger of malignant transformation, palliative measures such as cecostomy and appendicostomy are not to be considered except in the exceptional case. On the other hand surgical extirpation of the entire large intestine or several segments of it is a formidable procedure and is not to be undertaken lightly. Usually there is present a complicating anemia or some other debilitating condition.

Extirpation of the colon for diffuse lesions may be undertaken with two objectives in mind. If the polyps are largely confined to the colon proper, one considers sacrifice of the large intestine and the transplantation of the ileum into the rectum, thus saving the sphincteric mechanism. Small polyps that are present in the rectum may be destroyed by fulguration. When the rectum is involved in such a way as to preclude saving it, a three-stage operation is most desirable: first, an ileostomy; second, subtotal colectomy down to or near the rectosigmoid juncture; and, third, a combined abdomino-perineal resection of the rectosigmoid and rectum. A rapid loss of fluids from the body follows an ileostomy

and necessitates a considerable amount of rehabilitation before the patient is able to stand an extirpation of the colon without grave danger. It is however, possible to wait for months between the first and second stages if it is felt that malignancy has not already developed. Again after the second stage, a rest period may be given the patient before the resection of the rectosigmoid and rectum is undertaken.

In the case here presented, it is problematic whether the polyposis resulted from a bacillary dysentery or whether the dysentery was merely a complicating factor secondary to the congenital type of polyposis of the colon.

REPORT OF CASE

Mrs. R. G., a Cuban woman aged 23, was admitted to the Tampa Municipal Hospital June 17, 1933 complaining of fever and bloody diarrhea. She stated that the diarrhea began two months previously with about twenty stools daily and that for

Fig 1—Appearance after barium sulfate enema

the three weeks immediately prior to admission she had been obliged to remain in bed because of weakness. Her history was essentially negative. She had had two children and no miscarriages. There was no history of similar complaints in her family.

On admission her temperature was 103.8 F, pulse 120, respiration 20. The skin was hot and dry. There were several carious teeth. The abdomen was somewhat distended and generally tender, particularly in the left lower quadrant. The spleen was just palpable. Examination of the blood showed hemoglobin 52 per cent, red blood cells 3,800,000, white blood cells 19,000, polymorphonuclears 83 per cent, small lymphocytes 13 per cent, large lymphocytes 2 per cent, transitionals 2 per cent. Urinalysis was negative. A tentative diagnosis of either amebic or bacillary dysentery was made.

The patient continued to have a high fever and had from fifteen to twenty stools daily. July 10 the blood showed a complete agglutination to the Shiga bacillus in 1:80 dilution. Mean while the hemoglobin had dropped to 35 per cent with a red cell count of 2,130,000. Following a blood transfusion, July 25 the hemoglobin increased to 48 per cent. The patient was given serum treatment for dysentery but showed little improvement.

In the meantime Dr. Jack Halton, proctologist of the hospital, had examined the patient and on July 10 noted that there was marked proctitis present, extending from the internal sphincter to the sigmoid with a continuous seepage of bright red blood

from innumerable points over the whole surface of the rectal mucosa most marked from the internal sphincter to the lower valve of Houston. Proctoscopic examination on July 25 and again on August 4 showed some improvement. Dr. Halton reported on September 1 that there were few bleeding points and that the mucosa appeared practically normal. When the patient was discharged on September 14 she was much

Fig. 2—Appearance after opaque meal

improved and was advised to continue treatment at Dr. Halton's office.

September 24 just ten days after being discharged the patient was again admitted to the hospital. She stated that she had had a recurrence of symptoms because of poor home care and diet. Physical examination was essentially the same as when she was first admitted but her hemoglobin was down to 23 per cent. Transfusions were performed on October 18 and November 5. She continued to have from ten to fifteen stools daily. Her general condition was perhaps worse; she was very nervous and hysterical and was therefore rather uncooperative and difficult to manage. She was discharged the second time on Jan. 7 1934.

The patient was admitted to the hospital for the third and last time Aug. 3 1934. Her condition had grown steadily worse. She continued to have bloody stools. The laboratory tests for bacillary dysentery were negative as were also the Kahn and Kolmer examinations of the blood. Transfusions were given on August 21 and 28 and on September 4 and 15 but the beneficial results were only transient.

September 10 after the patient had been given a barium sulfate enema a roentgen study was made by Dr. J. C. Dickinson. The rectum and sigmoid filled fairly normally but only after the patient had experienced great difficulty in retaining the solution was the colon finally filled to a point just to the right of the vertebral shadow. There was complete absence of haustration and the outline of the colon was very irregular with innumerable filling defects throughout. As the observations were not sufficiently diagnostic a roentgen study of the entire gastro-intestinal tract was made. The stomach was fish hook in type and orthotonic. Neither in the stomach nor in the duodenum were there filling defects but in the second portion of the duodenum there was a moderate amount of dilatation. At the end of five hours the stomach was perhaps half empty and the coils of the ileum were definitely dilated. After seven hours had elapsed practically all the meal was retained in the

coils of the small intestine, apparently a normal condition except for dilatation in the coils of the ileum. A very small amount of the meal had passed completely through the colon and could be seen in the rectum. At the end of nine hours the colon was outlined throughout and presented a very feathery appearance with innumerable negative areas surrounded by thin lines of the opaque meal. Three hours later it presented much the same picture except that practically all the meal was in the sigmoid and rectum. The distal five or six inches of the ileum could still be seen barely outlined by a thin streak of the opaque material. At the end of twenty-four hours only a trace of the meal remained in the colon and its appearance had not changed.

In his report Dr. Dickinson concluded: "In trying to visualize the pathology that could produce this very unusual appearance of the colon it seems necessary to assume the presence of some diffuse pathological condition resulting in a very roughened surface of the mucous membrane with countless elevations allowing the opaque material to settle in the recesses between them. Innumerable small polyps would account for this condition. A roughly granulated surface due to ulceration and growth of granulation tissue might explain it. The delay in the terminal ileum is to me explained as a diffuse reaction of an irritated intestine distal to it. It is difficult to visualize so extensive an ulcer lesion. I am inclined to believe that the condition is one of polyposis."

Because of these conclusions the medical service requested a surgical consultation. On October 4 an exploratory laparotomy was done. Dr. Halton was present at this operation prepared to insert a sigmoidoscope into the colon. When the peritoneum was opened about a liter of clear serous fluid escaped. The cecum was firmly bound down and could not be delivered from the wound. It was therefore deemed inad-

Fig. 3—Pathologic specimen secured at autopsy

visable to open the intestine for the introduction of the sigmoidoscope. Moreover it appeared that this procedure was not necessary to confirm the preoperative diagnosis. About eight inches proximal to the ileocecal valve the ileum became markedly constricted and leathery in consistency. Above that point the ileum was distended. The colon was apparently full of solid matter and was rosy in consistency down to the sigmoid flexure where it returned to normal consistency. The appendix was large, free and normal in appearance. Unques-

tionably the condition was one of polyposis. The abdomen was closed in the usual manner without drainage.

The patient grew rapidly worse and died October 10. The condition at autopsy was as follows: There was about a liter of clear serous fluid in the abdominal cavity. The lower 12 cm of the ileum was moderately and uniformly thickened. The entire colon down to a point 40 cm from the anus was uniformly and diffusely thickened. The mucosa of the colon down to this point and up to the ileocecal valve was of strikingly shaggy appearance because of innumerable polypoid masses measuring on an average 3 cm long and from 3 to 4 mm in diameter. These polypi were either pink or bluish and many were tipped with hemorrhagic areas. The mucosa of the small intestine was normal. In about the center of the descending part of the ileum there was an ulcerated area but the mucosa was smooth. The principal cause of death was intestinal polyposis, the contributing causes were edema of the lungs and bilateral hydrothorax.

CONCLUSION

The pathologic specimen that confirmed the preoperative diagnosis, made possible by the roentgen study and corroborated the surgical observations, is shown in figure 3. The question arises as to whether the polyposis resulted from a bacillary dysentery or whether the dysentery was merely a complication of the polyposis. I am of the opinion that this case was one of polyposis of the colon of the congenital disseminated type, complicated by a bacillary dysentery that confused the picture and postponed the correct diagnosis until too late for relief to be given.

First National Bank Building

TRIPOLI AS A SOURCE OF SILICOSIS

CAREY P. McCORD, M.D.
CINCINNATI

Tripoli designates a form of silica much used in industry and is a substance possessing peculiar properties which distinguish it from the better known quartz or amorphous silica. The term "tripoli" is itself confusing, since it has been applied to other minerals, such as diatomaceous earth, and special types of limestone. The outstanding sources of tripoli are in southwestern Missouri and southern Illinois. Tripoli is widely described as amorphous, but at least some varieties are crystalline although the crystals are so minute as to warrant the term "cryptocrystalline."

Tripoli, when air dried in lumps is a light, fine textured minutely porous rock. Its lightness and porosity in its native state are believed to result from the fact that it is the siliceous skeleton of a mineral which in earlier days was much more compact, owing to the coexistence of limestone. The action of water throughout the ages has leached out the calcareous portion leaving behind the siliceous framework, hence a common name "rottenstone."

The individual grains of tripoli are approximately 0.0004 inch in diameter. After quarrying, drying and pulverizing tripoli is marketed for a great variety of industrial uses including polishes for painted surfaces, foundry facings as an ingredient in paint and soaps, as a filtering medium and as a rubber filler. As most of the uses of tripoli require minute particles it is reasonable to expect that this material might prove to be a prolific source of silicosis.

Tripoli, however, a mineral consisting of more than 99 per cent silica is rarely the source of clinical silicosis. In an earlier period when fallaciously the action of silica in inducing silicosis was attributed to the

cutting action of dust particles the absence of silicosis from tripoli was fully accounted for by the knowledge that tripoli particles are without sharp edges. With the advent of the chemical theory of the action of silica, it became untenable to exculpate tripoli as a source of silicosis because of its surface properties. Lately in court procedures in which silicosis has been falsely attributed to tripoli testimony by qualified industrial hygienists has denied that tripoli may be a source of that disease. The chief basis for this attitude lies in the absence of evidence of characteristic silicosis in the roentgenograms made on workers long employed in industries utilizing tripoli.

In order to determine whether or not tripoli is capable of producing silicosis, this substance was included as one of sixty-three minerals or combinations of minerals injected into the peritoneal cavities of animals. The technique employed essentially was that of Miller and Sayers.¹ One-tenth or two-tenths gram of tripoli in 2 cc of physiologic solution of sodium chloride was

Fig 1—Particles of tripoli suggesting soft spongy formation and absence of sharp cutting edges.

introduced into the peritoneal cavities of male guinea-pigs. The particle size for one specimen tested ranged below 5 microns for another below 42 microns. Twenty-eight other substances, similarly injected, served as suitable controls. The total number of animals employed was in excess of 300.

The chief reactions in the peritoneal cavity following the introduction of mineral substances in fine particles are according to Miller and Sayers, proliferative, inert and absorptive. Silica in quartz and amorphous form, together with minerals possessing a high content of silica, leads to the prompt formation of typical silicotic nodules. The development of proliferative tissue in the peritoneal cavity is presumptive proof that such a dust would be harmful for human beings, under conditions of extensive exposure by inhalation. Other dusts such as iron oxide, silicon carbide, titanium dioxide and aluminum oxide lead to inert reactions, such substances merely acting as a foreign body. Other

Response of the Peritoneal Tissue to Dusts Introduced as Foreign Bodies. *Am. J. Pub. Health* 25: 452 (April) 1935. Miller J. W. and Sayers R. R. The Physiological Response of the Peritoneal Tissue to Dusts Introduced as Foreign Bodies. *Pub. Health Rep.* 49: 80 (Jan. 19) 1935.

agents such as limestone gypsum silica gel and magnesium carbonate disappear through absorption. These reactions are specific for every individual dust.

At the end of thirty days all tripoli-injected animals were killed together with suitable controls, and inspections were made to determine the type of reaction. In every instance extensive and characteristic proliferation was established as present. The nodules produced were typical of those for quartz silica and in all respects permitted the interpretation that the action of cryptocrystalline silica in the form of tripoli is the stimulation of proliferative responses. In addition to characteristic nodule formation on the anterior abdominal wall as the chief site other nodules were irregularly found on the liver, diaphragm, omentum, intestinal wall, mesentery, testes, epididymis, cremasteric muscle and seminal vesicles. So far as reliance may be placed on this experimental procedure for the gaging of the fibrogenic properties of a dust it is to be recognized that tripoli is similar in its action to other forms of silica.

Notwithstanding the ready demonstration of experimental silicosis from tripoli the fact remains that workers in industry manipulating tripoli are rarely

Fig. 2.—Particles of quartz silica with sharp edges. Neither absence nor presence of sharp edges has any proved connection with the causation of silicosis.

involved and that, when they are affected, the severity of the disease is of low order. No adequate explanation of this can be proffered. In all likelihood no single factor is responsible, but some significance may be attached to the observation that the electrostatic charge of tripoli particles is such that particles tossed into the air tend to agglomerate into small loose clumps or masses and drop to the ground. Because of this property a shovelful of the finest and driest tripoli thrown into the air in an enclosed area falls to the ground with the formation of scarcely any discernible suspended dust. As a consequence, work places in which tripoli is manipulated are relatively free from dust. The electrostatic properties of tripoli particles may serve a highly useful purpose in the avoidance of silicosis in tripoli workers.

SUMMARY

Tripoli, a cryptocrystalline form of silica, readily produces proliferative reactions when injected into the peritoneal cavity of guinea-pigs. In all respects the

responses obtained are similar to those produced by quartz or amorphous silica, similarly introduced. The infrequency of clinical silicosis from tripoli as a cause cannot be attributed to any lack of tissue stimulating properties. The electrostatic charge of tripoli particles which tends to the formation of small clumps or masses of this suspended dust, may in some measure contribute to the low order of atmospheric dustiness in tripoli work places, and consequently to the low incidence of silicosis from this substance.

ENLARGEMENT OF THE LIVER IN
DIABETES MELLITUS

PER HANSSSEN, M.D.
COPENHAGEN, DENMARK

Medical textbooks are brief in their reference to the enlargement of the liver that is now and then found in cases of diabetes mellitus. Friedrich Unbehun¹ says: "The liver in diabetic patients ordinarily is enlarged when the disease is of long duration. Whether hyperemia, fat infiltration or incipient cirrhosis is the cause often cannot be settled intra vitam." Von Noorden and Isaac² refer to the symptom in the following words: "Doubtless, in many diabetic patients there is a moderate enlargement of the liver. Slight tenderness and increased consistency of the organ is most often demonstrated in these patients." However, von Noorden further states that in 25 per cent of the cases the enlarged liver was accompanied by other signs of circulatory disturbances, and he considers the hard and enlarged liver an accidental complication in diabetes mellitus. Joslin³ makes no mention whatever of enlarged liver as a symptom in diabetes mellitus, but Priscilla White⁴ writing subsequently from the same clinic, reports fatty infiltration of the liver in seven young diabetic patients at autopsy and gives evidence of the decrease in size of an enlarged liver under treatment.

It has therefore appeared strange to me how often we have found enlargement of the liver in young diabetic patients treated at the Steno Memorial Hospital. In two and a half years forty-four diabetic patients under 20 years of age were treated, and twelve of them had enlargement of the liver. During the same period the hospital also treated 231 diabetic patients over 20 years of age and out of that number one, aged 26, had an enlargement of the liver. These figures are no criterion of the frequency of this symptom, as the hospital preferably admits serious cases of diabetes in young people.

The ages of the thirteen patients, five male and eight female, are given in the accompanying table. No less than ten patients were 15 years of age or under.

All these patients were in a normal state of nutrition, two were shorter than the standard corresponding to their age, but whether this was due to diabetes cannot be decided.

We have attempted unsuccessfully to measure the size of the liver by means of roentgenography and

therefore have had to be content to measure how far the liver reached below the costal arch in the medioclavicular line, determined by bimanual palpation with the patient lying on his back. In one patient the liver extended two fingerbreadths below the level of the umbilicus. In five patients it reached the level of the umbilicus. In five it was felt two fingerbreadths below the costal arch. In two the liver was felt a good fingerbreadth below the costal arch.

In all these cases the liver was soft and softer than is usually found in any other form of enlargement of the liver. The surface was smooth and it was rarely possible to palpate a distinct edge. The liver moved freely during respiration and was not tender. In no case did we find an enlarged spleen, ascites or jaundice, or any sign of circulatory insufficiency.

The common feature in all these cases was a severe diabetes which was difficult to control. The disease had been present for from two to eight years with an average of four years and eight months, and had been treated with insulin for from two to seven years, with an average of four years and two months. With one exception all the patients received insulin twice a day and, in regard to their age, in very large doses. The patient who forms the exception had nevertheless,

owing to complications, for a long time received insulin twice a day, recently only once a day.

When a case of diabetes mellitus is admitted to a hospital it is always difficult to procure definite information regarding the condition of the patient prior to admission. To procure these particulars as far as possible, we put the patient during the first two or three days on the same diet and insulin as he has been reported to have had at home. Three of the patients had been on full diet minus sugar at home, the others on a diabetes diet containing from 80 to 200 Gm of bread and in a few cases 50 to 100 Gm of potatoes.

On admission, one patient, owing to infection, had pronounced acidosis (alkali reserve 38.5 volumes per cent of carbon dioxide). None of the others had a pronounced acidosis, as the ammonia values during the first three days varied between 0.50 and 1.20 Gm.

We determined the blood sugar of these patients fasting at 7 a. m., and at 11 a. m., 2 p. m., 5 p. m. and 10 p. m. Of the thirteen none had fasting blood sugar values below 300 mg per hundred cubic centimeters during the first three days of observation. The blood sugar values in the other analyses during the day usually were from 50 to 150 mg per hundred cubic centimeters. There was considerable glycosuria as a consequence of hyperglycemia in the morning hours.

During the hospital treatment the enlargement of the liver disappeared. How long it took for each of the thirteen patients we are unable to say. If the enlargement was slight we kept the patient only until the diabetes was well controlled, regardless of whether

the enlargement of the liver was still present. If the enlargement was considerable, we kept the patient, if possible, until the liver could no longer be palpated.

In the case in which the liver was largest it was ten weeks before the enlargement disappeared. In respect of three of the patients whose liver extended to the level of the umbilicus it took six, fifteen and seventeen weeks respectively for the enlargement to disappear entirely. In a fourth case in which there was as great an enlargement the liver was one fingerbreadth below the costal arch when the patient left the hospital after three weeks' treatment.

In the hospital all the patients were treated with a diet relatively poor in carbohydrates, containing 100 Gm of bread, 100 Gm of fruit and greens poor in carbohydrates and, in addition, fats sufficient for the calculated standard metabolism plus 50 per cent. With this diet and ordinary insulin twice daily it was not possible to avert the heavy fluctuations in the blood sugar values in the course of the day. All these patients were therefore treated with protamine insulinate. With this treatment the glycosuria is insignificant and the ammonia values are normal. In many of these patients, however, it was impossible to get Legal's test negative in the urine.

The tests of hepatic function that can be employed in the case of diabetes are of limited value as regards these thirteen patients. We observed the patients only in the period when the enlargement was subsiding, not in the period when it was developing. In five of the patients (including the two with the greatest enlargement) repeated determinations were made of the urobilin quantity in the twenty-four hour urine by means of Schlesinger's test. No pathologic urobilinuria was found, the concentration having been 1:10 at the highest. Hay's test revealed no choleic acid. Jaundice was not observed, and the color of the serum according to Meulengracht was under 5 in three of the patients with the greatest liver enlargement. The sedimentation rate of the erythrocytes and hemoglobin quantity in the blood were normal in all the patients.

In these patients one may presume that the liver was enlarged as a consequence of fat infiltration. The pathologic-anatomic description of a fat-infiltrated liver exactly accords with the physical conditions associated with this enlargement of the liver. That the enlargement can disappear so quickly is also an argument in favor of this assumption. Neither the physical conditions nor the clinical examination render it probable that the enlargement has been induced by a cirrhotic liver, a congestion of the liver or a glycogenous liver. We consider that this enlargement of the liver in diabetes mellitus is induced directly by the abnormal diabetic metabolism and that it cannot be regarded as an accidental complication. We have treated many young people with diabetes just as severe as in these thirteen patients without finding any enlargement of the liver, and clinically we cannot find any reason why this enlargement occurs only in some of the young patients with severe diabetes.

It would at first be natural to regard this enlargement of the liver as a link in the chain of symptoms so exactly described by Geelmuyden⁶ in dealing with various disturbances in the carbohydrate metabolism. The three principal links are fat migration, fat liver and ketonuria. The last is a constant symptom in these

disorders, and, as it was not found in these patients prior to admission to the hospital, the enlargement of the liver cannot be regarded as a link in this chain of symptoms

Clinical Notes, Suggestions and New Instruments

ARGYRIA BECOMING MANIFEST IN PREGNANCY

JOHN RAAP, M.D.
Fellow in Surgery, the Mayo Foundation
AND
HOWARD K. GRAY, M.D.
ROCHESTER, MINN.

Since Angelus Sala in 1647 first reported a case of argyria accounts of a similar nature have been by no means uncommon. However, a case in which argyria seemed to become manifest because of pregnancy presented a problem in physiochemistry worthy of consideration and report.

A woman, aged 47, admitted to the clinic Aug. 23, 1935, complained of gas on the stomach, abdominal distention, and discomfort in the right upper quadrant of the abdomen. It was found that she had gallstones; subsequently cholecystectomy was performed and was followed by uneventful convalescence.

The features in this case that we wish to consider were in no way related to the diseased gallbladder. Although the patient made no complaint of the peculiar color of her skin, we were immediately struck by the condition. On inquiry, she gave the following story:

Fifteen years before, she had undergone tonsillectomy. Following the tonsillectomy she had sprayed her throat with mild protein silver and since her physician had told her that it would do no harm, she had continued the use of the spray twice a day for almost five years. Near the end of this five-year period she had gradually discontinued the practice, so that for six months prior to the beginning of a pregnancy, nine and a half years before, she had not used it. In the first month of pregnancy she began to notice a bluish discoloration around the nose, and this discoloration gradually spread over the entire body. Within one month after the onset the peculiar discoloration had become intense and it had remained about the same for the last nine and a half years, although the woman never had resumed medication with mild protein silver. The pregnancy was without incident except that morning vomiting was unusually severe. The woman gave birth to a normal baby, whose skin has never shown any trace of the bluish discoloration.

On physical examination it was easy to make the diagnosis of argyria. The skin over the woman's face and neck was a dusky, bluish gray, the upper extremities including the finger nails, were also a dusky blue, and the thorax and to a lesser degree, the lower extremities were discolored. She presented somewhat the appearance of a deeply cyanosed patient. The sclerae were clear and there was practically no discoloration of the gums. When the cholecystectomy was performed, it was found that the stomach and intestine were likewise colored a bluish gray. Microscopic examination of the gallbladder and appendix, which were removed at operation disclosed silver granules in the tissues, and on chemical analysis it was found that there was 0.3 mg. of silver in 4 Gm. of gallbladder. Thus, the diagnosis of argyria was confirmed.

This case presented an interesting problem in physiochemistry. The usual history in silver poisoning is that the discoloration of the skin gradually becomes manifest. Zacks¹ reported a case in which the argyrosis came on suddenly following exposure to ultraviolet rays from a lamp, but rapid discoloration of the skin is not generally the rule. In our case the question arises as to why the discoloration developed rapidly, early in pregnancy six months after discontinuance of the medication with mild protein silver. It is also of interest that the baby escaped the argyrosis.

Much less is known of the pathology and chemistry of argyria than of the symptoms. It is common knowledge that colloids

do not usually diffuse through animal membranes, therefore in colloidal silver solutions the silver ions must be freed before they can enter the tissue fluids. Once liberated, the silver ion forms complex, but soluble, compounds of silver in the intercellular tissue fluids. According to Scheffel,² when the silver laden tissue fluids reach the intracellular substances colloidal compounds of silver may again be formed which go through chemical alterations in which the silver ion is once more split off. If a definite balance can be maintained between silver in the tissue fluids, particularly the intracellular elements, and their final deposition, deposits of silver, or argyria, can be avoided. Scheffel, however, wrote "It is conceivable that a great many physical as well as chemical alterations may take place within the cellular elements which may entirely prevent the association from the cell of silver ions. What may occur to prevent the silver ion from leaving the tissue cells?"

If a state of partial dehydration or a state of alkalinity should exist the intracellular ionic silver either could not at all leave the cells or its normal exit may be considerably retarded—thus leaving an intracellular disposition for the subsequent formation of macroscopic symptoms of argyria."

This explanation of the physiochemistry of argyria may answer the question why the discoloration occurred rather suddenly in our case early in pregnancy. Prior to pregnancy there was probably a balance of the intake and outgo of silver within the cells. In the course of pregnancy the patient vomited a great deal and this may have resulted in mild dehydration, which prevented the intracellular ionic silver from leaving the cells. It seems rather certain that a disturbance of metabolism of some sort attributable to pregnancy, must have been responsible for the appearance of the argyria. This supports Scheffel's contention that argyria may be prevented in most cases by careful attention to the patient's metabolism of water and chloride.

CARDIOVASCULAR AND PERIPHERAL VASCULAR DISEASES

TREATMENT BY A MOTORIZED OSCILLATING BED

C. E. SANDERS, M.D., KANSAS CITY, KANSAS

It has long been known that improvement in peripheral blood circulation and cardiac efficiency can be obtained by certain postural changes, utilizing the effects of gravity to facilitate improved blood flow and tissue fluid exchange. This has been accomplished by elevation of the extremities, changing the position of the trunk and the application of elastic pressure over

Fig. 1 Oscillating motorized bed adjusted so that the excursion of the bed will be an approximately equal 13 inch drop of each end alternately. Two speeds are available: three and one-half or seven and one-half minutes from low foot to high foot and return.

the more distant portions of the circulatory tree. The means adopted to accomplish these ends have included attachments to the ordinary hospital bed, specially designed chairs or mechanical arrangements in which centrifugal force can be used and, in addition, certain negative and positive air pressure machines.

From the Division of Surgery, the Mayo Clinic.
1 Zacks, M. A. Argyria in a Child Following Intranasal Use of Argrol. Laryngoscope 42: 680-686 (Aug.) 1933.

2 Scheffel, Carl. The Physiochemistry of Argyria. M. Rec. 140: 205-207 (Aug. 15) 1934.

My interest in the problems of peripheral edema dates back several years. I observed that elderly patients with fractures of the lower extremities necessitating immobilization for several months developed edema that persisted for unduly long periods of time. Following the institution of postural changes in these cases, wherein the vessels were completely emptied by elevation

Fig 2—Adjustment for failing compensation with edema of extremities and lungs. When thus set the bed has the extent of excursion shown in this illustration and in figure 3. With the brick elevated the patient rarely suffers from dyspnea. With the crank adjustment at the foot of the bed the excursion can be set for any degree of low head position desired as the patient improves.

and completely filled by lowering, the edema would rapidly disappear. Similar postural changes regularly instituted were tried on patients suffering from cardiac edema, with surprisingly good results. The accomplishment of these postural changes in cases of cardiac insufficiency could be obtained only through active movements, inconvenient and exhausting to the patient.

Fig 3—Adjustment for failing compensation with edema of extremities and lungs. Compare with figure 2. Note that the frame does not go lower than level.

This bed has been made and introduced as a convenient and comfortable method of accomplishing these postural changes regularly and systematically, as well as passively on the part of the patients, who remain in a state of relaxation in bed with complete conservation of their energy.

Patients actually enjoy the continuous alteration of posture with its changing distribution of body weight against the bed. Peculiarly enough, patients suffering from myocardial insufficiency with pulmonary edema tolerate the excursions of the bed without pronounced dyspnea.

I have concluded from observation and treatment of a number of patients that by utilizing gravity completely to empty and fill the veins and capillaries intermittently and regularly, it has a beneficial effect in many cardiovascular and peripheral vascular diseases. Unquestionably, filling and emptying the

veins and capillaries at regular intervals represents a type of vascular gymnastics which restores their muscle tone.

Clinical improvement of patients treated on this oscillating bed for congestive heart failure with resultant disturbance in distribution of tissue fluid manifests itself in two ways: (a) by utilizing gravity to facilitate the return flow of blood to the heart, subsequently restoring lost muscle tone, and (b) by improvement in cardiac function. Physiologically, the so-called law of the heart may explain this fact. This law, in brief, states that a rapid inflow of blood with thorough distention of the heart chambers results in a full force contraction while a slow inflow with imperfect filling results in a weak contraction.

In peripheral vascular diseases of diabetic, arteriosclerotic or thrombo-angitic types treated on this bed marked improvement in local circulation is noted. This is indicated by a definite improvement in the temperature of the affected part as well as relief of pain. It is also noted that ulcers heal and the progress of gangrene is stopped.

Fig 4—For postoperative treatment hip fracture and similar conditions. This illustration and figure 5 show the toggle attachment which reduces the cycle from approximately 26 inches to one of 10 inches. The advantage in this attachment is a level mattress as the excursion is so slight that the patient does not slide and no elevation of knees or head is necessary. This cycle cannot be altered with telescopic pitman.

Physiologically, the improvement is due to two factors: (a) relief of venous stasis and back pressure, and (b) intravessel aspiration, promoting better arterial blood supply.

I realize that there are other factors outside the circulatory tree which influence the distribution of tissue fluid and its

Fig 5—For postoperative treatment hip fracture and similar conditions. Compare with figure 4.

constituents resulting in abnormal collections of tissue fluid, which are not amenable to improvement of the circulatory state but necessitate other therapeutic principles not within the realm of this presentation.

The device herein presented provides a means of applying the principles of gravity to the actual treatment of patients in a convenient and comfortable manner. In brief it is a motorized hospital bed with two speeds, which alternately elevates and lowers the head and the foot. The amplitude and rate of

oscillation are adjustable in a simple manner. The motor control button is placed near the patient so that he or the attendant can interrupt the excursion at any desired position.

I am convinced, from a study of results obtained through the utilization of gravity in the treatment of a number of patients with myocardial insufficiency during the past three years, that improvement is more certain and rapid than that which can be obtained through the use of the more conventional methods, also that when compensation and vascular tone have been restored, the improvement is more permanent. It is not implied that the cardiac patient must resign himself to this continuous treatment after restoration of vascular and cardiac tone. Studies are being made in several institutions to determine the applicability of this method of treatment in a wide variety of cases.

MECHANICAL CONSIDERATION OF THE BED

The frame of the bed is substantially constructed of cast iron and consists of two segmental side members, which are securely braced by the tube and tie-rod method. The frame is mounted on rubber-tired casters, which assure quick, easy and noiseless movement about the room. Attached to the spring portion of the bed are two horizontal racks, which engage the teeth of the segments of the frame thus admitting a free, smooth and quiet movement in the operation of the bed.

Fig 6—For peripheral vascular diseases. The telescopic pitman is adjusted with crank and set so that the cycle of low foot and high foot will be equal.

The power plant consists of a specially constructed ball bearing worm type gear case with a speed reduction of approximately 6,000 to 1. It is driven by a one-third horse power motor with V belt and pulley drive. The motor, in addition to its cushioned base construction, is mounted on a spring steel plate which causes it to float reducing vibration and insuring reasonably quiet operation.

A pair of disks, one at each side of the transmission case having wrist pins which engage the lower ends of the pitman furnish the driving force which propels the spring portion of the bed. The pitman, which is of the telescopic type, is attached to a cross member at the foot of the spring portion of the bed and may be lengthened or shortened by a simple screw adjustment operated by a crank at the foot of the bed.

For an extremely short cycle in the movement of the spring portion a separate toggle attachment is provided which may be attached in a few minutes allowing the bed to operate continuously throughout the day or night without back rest or knee elevations. The drop of either end of it is so slight that the patient does not slide on the mattress. One crank answers for the adjustment of the head or lower extremity elevations as well as for the operation of the telescopic pitman, which produces a greater or lesser cycle of movement of the spring portion of the bed. Three and one half minutes is required for one complete cycle from low to high point and return. The patient or attendant may stop this cycle at will in any desired position.

1401 Southwest Boulevard

FULCRUM FOR BONE FORCEPS

(AN INSTRUMENT TO BE USED IN CONJUNCTION WITH LION JAW FORCEPS)

HAROLD LUSSKIN M.D., NEW YORK

Most surgeons have had occasion to use profanity when trying to approximate overriding ends of fractured long bones even when these ends are exposed to view through an incision. Traction with the patient on the operating table seems insufficient and uncontrolled as to both force and direction. Besides, even though the ends of the fragments are held in the grasp

Fig 1—Pipe fulcrum made of a piece of $1\frac{1}{2}$ inch pipe or metal tube to which two loops of brass are fastened. The pipe can be made of brass and the loops welded on. The loops here are held in place by nuts within the pipe.

of the lion-jaw forceps, to pull them down and place them end to end is extremely difficult, sometimes impossible.

It was this difficulty which prompted the construction of a simple device illustrated here. It is easy of manufacture. It acts as a fulcrum for the lion-jaw forceps.

Fig 2—A each lion jaw forceps is passed through a loop in the pipe fulcrum and the fragments of the fractured bone are grasped. The handles of the forceps are approximated as shown by the arrows. B with the handles approximated the bone ends are brought into one plane correcting the overriding. The handles are then moved in the directions indicated by the arrows on the fulcrum causing it to rotate until the bone ends are in alignment. C the bone ends are now in alignment. The pipe fulcrum is shown in its rotated position. The bone ends can now be brought together and held by an assistant until they are secured in place.

The instrument (fig 1) consists of a piece of pipe $1\frac{1}{2}$ inches in diameter and 2 inches long. On opposite sides of this pipe are placed metal loops big enough to permit lion-jaw forceps

to slip through. The forceps are passed through these loops and the bone fragments grasped. The handles of the forceps are approximated, the pipe acting as a fulcrum between them, and the fragments brought into alignment (fig 2).

LYMPHOGRANULOMA INGUINALE ITS INCIDENCE IN ST LOUIS

S H GRAY M D GEORGE A HUNT PH D PAUL WHEELER M D
AND J OWEN BLACHE M D ST LOUIS

For many years, cases of lymphogranuloma inguinale have been reported individually or in small groups under a variety of more or less descriptive names. The literature on this subject has been completely reviewed by Stannus¹ in his recent book and need not be dealt with here. With the advent of the Frei test² and its rather widespread use and acceptance, the clinical and public health importance of this disease is only just beginning to be appreciated. The only large series reported in this country is that of DeWolf and Van Cleave,³ who found fifty-eight positive cases in 1,010 persons tested with the Frei antigen. In St Louis the first case was described in 1933 by Ives and Katz.⁴ In 1935 Rainey and Cole⁵ reported twenty-three cases.

In our studies we have tested out, by means of the Frei reaction, the incidence of lymphogranuloma inguinale in the white hospital population at City Hospital No. 1, in the colored hospital population at City Hospital No. 2, and among the prostitutes appearing at the Municipal Venereal Clinic.⁶

The antigens were prepared from colored and white patients according to the directions given by Frei. The pus aspirated from an inguinal node of a patient with a strongly positive Frei reaction was diluted five times with 0.85 per cent saline solution, and heated at 60 C. for two hours the first day and one hour the second day. The product was then tested for sterility by bacterial culture and for activity by intradermal injection of known positive cases of lymphogranuloma inguinale. The patients from whom the pus was obtained for use as Frei anti-

ground by shaking with sterile glass beads in approximately five volumes of sterile saline solution.

The antigens used differed in two respects from those used by DeWolf and Van Cleave. Our own antigens were 1:5 pus dilutions (recommended by Frei) rather than 1:10. They contained no preservative, whereas those of the Cleveland investigators contained 0.25 per cent phenol. We refrained from adding any preservative, because we had done no work on the effect of disinfectants on the activity of the antigens. Hence we have used care in handling the antigens and have relied on frequent culture of the material as a check on the sterility of the product. Our antigens have remained active for at least nine months.

Each antigen prepared was used on colored and white patients. The marked difference in the response of these two groups acted as a further check on the antigen.

TABLE 2—Results of Tests in Series 1

	Number of Cases	Frei Negative	Frei Positive	Clinically Active	Clinically Inactive
Male	106	66	40 (38%)	20	15
Female	103	49	54 (52%)	13	41

TABLE 3—Results of Tests in Series 2

	Number of Cases	Frei Negative	Frei Positive	Percentage of Positive Cases
Male	92	52	40	43
Female	172	114	58	34

In table 1, we have summarized the results of our study. The preponderance of this disease in the colored race is outstanding. The white persons in our group come from the lowest economic level. This group would be expected to exhibit the greatest percentage of so-called social disease in their race. By consulting the ratio of positive Kahn reactions in the white and colored groups, the relative proportions of the occurrence of lymphogranuloma inguinale become even more striking. Just what factors aside from race susceptibility are involved it is difficult to say. The difference in economic and hygienic standing is too slight to account for a 10:1 ratio. Though most of the white males with clinical lymphogranuloma inguinale gave a history of sexual contacts with colored women, the lack of control figures prevents us from emphasizing anything on this point. Those who have interested themselves in this subject say that interracial sexual relationships are fairly common in this and southern regions.

In the prostitutes we made no attempt to study the presence of active manifestations of lymphogranuloma inguinale, nor did we delve into their histories to determine clinical activity in the past. The Frei tests on the white patients were performed at a time when no clinically active cases were present in the wards of the City Hospital. The Frei tests on the colored patients were performed in two series. In series 1 (table 2), many active cases were in the hospital at the time of study. The clinical features of these cases together with many others will be reported later. The patients for series 1 were derived mostly from the genito-urinary and gynecologic wards. It is interesting that the figures in this table include thirty-five patients suffering from tuberculosis. Only two were Frei positive (5.8 per cent). There was no difference in the range of the age of this group as compared to the others. Evidently the chronicity of and debility produced by tuberculosis greatly diminished the opportunity for sexual contacts. These results, in a way tend to confirm the accuracy of the Frei test and they attest the accuracy of the antigens used.

In the second series (table 3), patients in the medical wards were used exclusively. No known clinically active cases were present at the time.

We were greatly surprised to find a history of a previous active lesion missing in most of the patients who gave a positive Frei reaction and had no active lesion at the time. Our tendency was to attribute this to the ignorance of the patients. The evanescence of the primary lesion and the infrequency of

5 Rainey Warren and Cole W. H. Lymphogranuloma Inguinale. Its Relation to Structure of the Rectum. Arch. Surg. 30: 820 (May) 1935.

6 We are indebted to Dr. Bredeck, health commissioner and to Dr. Kavanaugh, director of the Municipal Venereal Clinic for permission to test this group.

7 At the present time a commercial supply of a killed suspension of Ducrey bacillus (dimeles vaccine) is not available in the United States for therapy or for diagnosis of chancroidal infection by a skin sensitivity test. Our first supply was obtained through the kindness of May and Baker Ltd., London. The organism has been difficult to obtain in pure culture free from pus or blood. Recently one of us has described a method of cultivating the Ducrey bacillus for the preparation of a saline suspension (Hunt C. A. The Cultivation of the Ducrey Bacillus for the Preparation of Vaccine. Proc. Soc. Exper. Biol. & Med. 33: 293 [Nov.] 1933). We are now using our own vaccine for the differential diagnosis of chancroid.

3 Patent applied for

like the distal cuff throughout the negative phase, plays no part in the closed system. In this manner each cuff functions through the same phase of each cycle to its best mechanical advantage, the distal through the positive, and the proximal through the negative. One cuff is not required to be resistant to both positive and negative pressures but merely to work efficiently throughout one phase of the cycle.

This combination of cuffs in my hands, has proved entirely satisfactory, and we feel that its use with the passive vascular exercise unit will increase the efficiency of an extremely valuable therapeutic aid.

Greenspring Avenue and Forty-First Street

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS

HOWARD A. CARTER, Secretary

McINTOSH JUNIOR METRO-COAGULATOR ACCEPTABLE

Manufacturer: McIntosh Electrical Corporation, Chicago

This unit is recommended by the manufacturer to members of the profession who require a high frequency current generator solely for electrocoagulation and electrodesiccation. The firm informs the Council that this unit is not intended for medical diathermy.

The machine was operated for a period of one hour, and the resulting temperature rise of the transformer was within the limits of safety established by the Council. Other electrical parts were inspected and found to be safe and serviceable. The manufacturer states that a d'Arsonval solenoid is employed to generate the high frequency d'Arsonval current. The spark gap is of 8 point (four gap) air-cooled type. Figure 2 is a diagram of the connections. The apparatus is enclosed in a leatherette-covered carrying case and weighs about 18 pounds. The fittings of the unit are chrome plated.

In a clinic acceptable to the Council the machine was given a practical test over a period of several months. The investi-

Fig. 1—McIntosh Junior Metro Coagulator

Fig. 2—Diagram of connections

gator reported that the apparatus will perform satisfactorily for the purposes for which it is recommended and that it has been used with success for both light desiccation and coagulation of tissues.

The Council on Physical Therapy voted to include the McIntosh Junior Metro Coagulator in its list of accepted apparatus.

LEPEL DIATHERMY MACHINE ACCEPTABLE (TYPE RFC)

Manufacturer: Lepel High Frequency Laboratories, Inc., New York

This machine is of the conventional type diathermy unit and is recommended for surgical and medical diathermy. It makes use of the spark gap for creating a high frequency energy.

The manufacturer submitted data containing a report of tests of the unit for power input and output, and for its spark gap and transformer temperature rise. The results recorded in the data were in agreement with the observations of the Council's investigator and in conformity with the Council's standards for diathermy machines. The circuit of this machine is similar to that of the Lepel High Frequency Combination Machine already accepted by the Council.

Lepel diathermy machine type RFC

This machine was used in a clinic acceptable to the Council for several months. It proved to be satisfactory, both as a medical diathermy machine and as a surgical unit.

The Council therefore voted to include the Lepel Diathermy Machine, Type RFC, in its list of accepted apparatus.

ALTHERM SINUS PAD ACCEPTABLE

Manufacturer: Wagenseil Surgical Appliance Company, Inc., Brooklyn

This heating pad is recommended by the manufacturer as a convenient method of applying heat where heat is required. It is constructed of heavy gage rubber, the bottom or face side being shaped for application to the forehead with a detachable rubber band for holding the pad to the head. The pad is about 3 3/4 by 1 3/4 inches in size and weighs about 8 ounces.

Altherm sinus pad

The manufacturer claims that the mixture (heat retaining element) used in the pad is nonirritating and noninflammable. After the pad has been boiled for a short time, the contents liquefy. After being removed from boiling water and in ordinary room temperature, the mixture gradually recrystallizes as it gives off heat. The action makes use of the latent heat of crystallization. The contents do not need to be renewed.

The total weight of the thermophoric mixture amounts to about 6 ounces avoirdupois, or approximately 148 Gm of which the component parts are:

Sodium acetate	90.5%	135.1 Gm
Glycerin	3%	4.5 Gm
Sodium sulfate crystal	2%	3.0 Gm
Sodium sulfate anhydrous	4.5%	6.7 Gm
	100%	149.3 Gm

The pad is prepared for therapeutic use by placing it in boiling water and boiling it for not more than ten minutes. After this, the element will be found to be partially liquefied and during recrystallization will give off heat at a comparatively even temperature for approximately one hour, after which the element will have solidified completely. The temperature will range from approximately 114 F down to approximately 108 F.

The pad cannot be used until boiled, so it is necessarily sterilized before each application.

An investigator tested the pad for the Council in a recognized clinic. He reported that the pad might have value in certain types of frontal sinusitis in which heat is indicated as a therapeutic measure.

Because the pad is considered simple, safe and clinically effective, the Council on Physical Therapy voted to include the Altherm Sinus Pad in its list of accepted devices.

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING
REPORT

PAUL NICHOLAS LEECH Secretary

PHAGOID-STAPHYLOCOCCUS, PHAGOID-BACILLUS COLON, PHAGOID-STREPTOCOCCUS HEMOLYTICUS AND OTHER BACTERIOPHAGE PREPARATIONS OF THE PHAGOID LABORATORIES, INC, NOT ACCEPTABLE FOR N N R

In 1934 the Council sponsored an exhaustive report on bacteriophage therapy by Eaton and Bayne-Jones (*THE JOURNAL*, Dec 8, 1934, p 1769, Dec 15, p 1853, Dec 22, p 1934) in which it was brought out that in view of the present status of knowledge concerning bacteriophage preparations, none of these products could be accepted for inclusion in New and Nonofficial Remedies. At that time the Council considered the merits of individual commercial preparations among them a line of products marketed by the Allen-Sandlin Laboratories, Inc, of Louisville. At about that time the Allen-Sandlin Laboratories, Inc, went into bankruptcy and the business was taken over by the Phagoid Laboratories, Inc. The latter concern formally presented for the Council's consideration Phagoid-Staphylococcus, Phagoid-Bacillus Colon and Phagoid-Streptococcus Hemolyticus. In presenting these products the firm expressed a desire to market them in such a way as to obviate the numerous objections raised by the Council in its consideration of the Allen-Sandlin products.

The advertising submitted by the Phagoid Laboratories, Inc, is open to the same objection as was found in that of the Allen-Sandlin Laboratories, namely, that it represents a mixture of some rational and some justifiable statements with numerous unwarranted therapeutic claims, especially as regards the specificity of certain products. In general, the material is overenthusiastic and uncritical. There is so much of this sort of thing that the Council feels it unnecessary to go into detailed discussion of this advertising.

Although it has formally presented for the Council's consideration only the products just enumerated, the Phagoid Laboratories, Inc, has sent advertising matter for others of its "Phagoid" preparations. In the list given in the general booklet *Phagoid, Lysed Bacteria with their Antivirus with the Specific Lysins* apparently a complete list is given, as follows: Phagoid-Arthritis, Phagoid-Mucous Colitis, Phagoid Catarrhal Mixture, Phagoid-Bacterial Endocarditis, Phagoid-Typhoid, Phagoid-Pruritus, Phagoid-Mixed Infection, Phagoid-Pneumococcus Polyvalent, Phagoid-Gonococcus, Phagoid-Pertussis, Phagoid-Streptococcus, Phagoid-Staphylococcus, Phagoid-Bacillus Colon and Phagoid-Autogenous.

The Council found the following objections to the nomenclature used for these products:

USE OF THE NAME PHAGOID

Regardless of whether used as a proprietary name or as a generic term to apply to all products manufactured by the firm, the term Phagoid seems unfortunate and inappropriate. Literally the term means like, resembling or having the form of a 'phage'. The products under consideration are said to be mixtures of bacteriophage, lysate and antivirus. The term Phagoid is not only not descriptive of this mixture but conveys an erroneous idea as to its nature, certainly it should not be used as a designation for individual products as it is used in the advertising literature of the Phagoid Laboratories. The use of the term antivirus is regarded as also unfortunate although it seems to be fairly well established in scientific literature and is also used by Besredka as a name for the hypothetical substances in filtrates which specifically inhibit the growth of bacteria and produce rapid local immunization.

USE OF CLINICAL NAMES

The use of clinical names in connection with the use of various Phagoid products, especially when these names indicate conditions of diverse etiology, is highly objectionable, for example, Phagoid-arthritis, -mucous colitis, -catarrhal mixture, -bacterial endocarditis, -pruritus, -mixed infection.

It is doubted whether a potent bacteriophage has been found for the gonococcus or the pertussis bacillus. Phagoid streptococcus is entirely too general a term and, in fact, so is Phagoid hemolytic streptococcus.

Since there are a great many different strains of hemolytic streptococci, nonpathogenic, pathogenic and specific for different diseases differing in antigenic structure as well as in cultural characteristics, relatively few of the hemolytic streptococci have been shown to be sensitive to bacteriophage.

The claim for usefulness of Phagoid-mucous colitis is based on the assumption that Bagen's streptococcus or diplococcus is the cause of this condition. This assumption is not well founded and in fact Bagen's organism has not been shown to be a specific entity distinguishable from other streptococci that may be found in the colon.

In view of the exhaustive report on bacteriophage therapy referred to at the beginning of this report, the Council would not be warranted at this time in the acceptance of any bacteriophage preparations for inclusion in New and Nonofficial Remedies. Certainly, the products of the Phagoid Laboratories, Inc, as now marketed, are quite unacceptable. Other objections of the Council to these products may be discussed under the following headings:

BACTERIOPHAGE PREPARATIONS EXPERIMENTAL

The conflicting results reported in the literature regarding the usefulness of bacteriophage preparations clearly indicate that for most of the conditions mentioned in the list of Phagoid products bacteriophage preparations must be regarded as in the experimental stage.

SPECIFICITY OF BACTERIOPHAGE

It is known that although bacteriophages may show considerable latitude in their activity toward different races or even different species of bacteria they often show a very narrow specificity in acting on only certain strains of bacteria within a single species. For this reason it would be necessary to check the action of any particular bacteriophage not only against the strains of bacteria used in its preparation but also against other strains of the same species if a stock preparation of bacteriophage is to be regarded of use in any infection. On the other hand, the listing of Phagoid autogenous might indicate that the Phagoid Laboratories is prepared to make an autogenous Phagoid from any culture with material submitted. The firm's ability to do this is regarded as a very doubtful possibility. When this report was sent to the firm, it replied concerning this statement: "It has never been stated or inferred that the Phagoid Laboratories were prepared to make an autogenous vaccine from any culture with material submitted." It is pointed out that the statement in question was made on the basis of the following, which appeared in one of the circulars submitted by the firm:

The Laboratory will furnish swabs packaged in suitable medium for mailing and will prepare autogenous Phagoid from the organisms submitted.

The Council declared the bacteriophage preparations of the Phagoid Laboratories, Inc, unacceptable for inclusion in New and Nonofficial Remedies because they are offered to the medical profession with unscientific, unwarranted claims, thus encouraging physicians to use in a routine way medicaments the therapeutic value of which has not been established, and because they conflict with other rules of the Council.

When a statement of the Council's consideration was sent the Phagoid Laboratories, Inc, the firm replied expressing its intention to revise drastically its claims and literature in accord therewith. The firm made some minor objections which have been taken into account in preparation of the foregoing statement. The firm's letter, however, offered no basis for modification of the Council's essential reason for rejection of these

products, namely, that there is not sufficient evidence to warrant their inclusion in New and Nonofficial Remedies. The Council therefore reaffirmed its rejection of Phagoid-Staphylococcus, Phagoid-Bacillus Colon, Phagoid Streptococcus Hemolyticus and other bacteriophage preparations of the Phagoid Laboratories, Inc, for this reason and in order that the medical profession might be informed, authorized publication of this report of its consideration

Committee on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

FRANKLIN C. BING, Secretary

- 1 DOLE BRAND HAWAIIAN PINEAPPLE SLICES, WATER PACKED
- 2 DOLE BRAND HAWAIIAN PINEAPPLE TIDBITS, WATER PACKED

Manufacturer—Hawaiian Pineapple Company, San Francisco

Description—1 Canned peeled, cored and sliced Hawaiian pineapple, processed and packed in water

2 Canned Hawaiian pineapple tidbits packed in water

Manufacture—1 The method of manufacture is essentially the same as for Dole 1 Hawaiian canned pineapple slices (THE JOURNAL, April 8, 1933, p 1106) with the exception that water is used to fill the cans

2 The method of manufacture is essentially the same as for Dole 1 Hawaiian canned pineapple tidbits (THE JOURNAL, April 8, 1933, p 1106) with the exception that water is used to fill the cans

Analysis (submitted by manufacturer) —

	Sliced per cent	Tidbits per cent
Moisture	85.6	88.0
Total solids	14.4	12.0
Ash	0.4	0.3
Fat (ether extract)	0.02	0.02
Protein (N \times 6.25)	0.3	0.3
Total sugar as invert sugar	11.6	9.7
Crude fiber	0.3	0.2
Carbohydrates other than crude fiber (by difference)	13.4	11.2
Titratable acidity as citric acid	0.4	0.5
Iron (Fe)	0.0004	0.0003
Manganese (Mn)	0.0003	0.0002
Copper (Cu)	0.0002	0.0001
Calcium (Ca)	0.01	0.01
Magnesium (Mg)	0.01	0.01

Calories—1 0.5 per gram, 14 per ounce

2 0.4 per gram, 11 per ounce

Vitamins—Biologic assay shows canned pineapple to contain vitamin A and to be a good source of vitamins B and C. Practically equivalent to the fresh fruit in A and B, slightly inferior in C.

Claims of Manufacturer—Fancy grade representing fruit most uniform in color, flavor, texture and workmanship. Packed in water. Practically equivalent to the fresh fruit in nutritional values.

HALE'S PRIDE BRAND PURE GRAPEFRUIT JUICE

HALE'S PRIDE BRAND PURE ORANGE JUICE

Distributor—Hale Halsell Company, McAlester, Okla.

Manufacturer—Dr. P. Phillips Company, Orlando, Fla.

Description—Canned Florida grapefruit and orange juices sweetened with added sucrose and retaining in high degree the original natural vitamin content, the same as Dr. P. Phillips Pure Florida Grapefruit Juice (THE JOURNAL, Jan 7, 1933, p 43) and Dr. P. Phillips Pure Florida Orange Juice (THE JOURNAL, Dec 3, 1932, p 1948).

1 HOME BRAND GOLDEN SYRUP

2 FOLEY'S BRAND AMBER SYRUP

Distributors—1 Griggs, Cooper & Company, St. Paul
2 Foley Bros. Grocery Company, St. Paul. Subsidiary of Griggs, Cooper and Company.

Manufacturer—Griggs, Cooper and Company, St. Paul.

Description—Table syrups, corn syrup with refiners' syrup.

Manufacture—Corn syrup and refiners' syrup are mixed with boiling water in definite proportions, heated, strained and automatically filled into cans.

Analysis (submitted by manufacturer) —

	per cent
Moisture	23.7
Ash	1.4
Fat (ether extract)	0.0
Protein (N \times 6.25)	0.2
Reducing sugars as dextrose	30.4
Sucrose	7.0
Dextrins (by difference)	37.2
Acidity as HCl	0.07
Sulfur dioxide	none
pH	5.2

No methods are available for accurately determining the composition of syrups of this nature, therefore the foregoing analysis is roughly approximate.

Calories—3 per gram, 85 per ounce.

Claims of Manufacturer—Recommended for use as an easily digestible and readily assimilable carbohydrate supplement to milk in infant feeding and as a syrup for cooking, baking and the table.

HOOS' PROTEIN MILK

Distributor—Louis Hoos, Scientific Milk Products, Chicago.

Manufacturer—The Borden Sales Company, New York.

Description—Spray dried mixture of milk curd (casein and milk fat) and cultured skim milk.

Manufacture—Fresh milk, produced under sanitary conditions, is pasteurized (63 C, thirty minutes), and coagulated with rennin. The curd (casein and fat) is separated from the whey, mixed with cultured skim milk prepared by adding a pure culture starter to pasteurized skim milk and the mixture is spray dried and packed in cans.

Analysis (submitted by distributor) —

	per cent	Diluted with water (3 oz. to 1 quart) per cent
Moisture	2	92.6
Ash	5	0.4
Fat	30	2.5
Protein (N \times 6.38)	39	3.0
Lactose (by difference)	21	1.5
Titrate acidity as lactic acid	3	

Calories—5.2 per gram, 148 per ounce.

Claims of Manufacturer—For use under the direction of a physician in nutritional disturbances of infancy, or when a modified milk food richer in protein and lactic acid and lower in lactose than dried whole milk is desired.

CELLU BRAND YELLOW STRING BEANS, WATER PACKED

Distributor—Chicago Dietetic Supply House, Inc., Chicago.

Packer—Geneva Preserving Company, Geneva, N. Y.

Description—Canned yellow string beans, packed in water.

Manufacture—Selected wax beans, picked at the proper degree of maturity, are snipped, sorted, graded, again inspected, blanched, washed and packed in cans. The cans are filled with hot water, sealed and processed.

Analysis (submitted by distributor) —

	per cent
Moisture	94.8
Total solids	5.2
Ash	0.7
Fat (ether extract)	0.1
Protein (N \times 6.25)	0.9
Crude fiber	0.4
Starch (diastase method)	2.2
Carbohydrates other than crude fiber (by difference)	3.1

Calories—0.2 per gram, 6 per ounce.

Claims of Manufacturer—Choice quality beans packed without added sugar or salt. For use in special diets in which sugar or salt is proscribed or in quantitative diets of calculated composition.

CONCUSSION OF THE SPINAL CORD

Much more knowledge seems to be available concerning concussion of the brain than of the corresponding lesion of the spinal cord. It is interesting, moreover, that information has accumulated concerning symptomatology of the former condition and pathology of the latter.

The clinical manifestations of concussion of the spinal cord include a multiplicity of clinical pictures, with apparently grave initial symptoms, which disappear or tend to improve rapidly. The symptoms are not, however, always transient in character, and serious, permanent disturbances may result. The condition varies, depending on the particular segment of the cord that is involved as well as on the evolution of the lesions.

Because of its relatively greater fixation and rigidity and its greater exposure to trauma the thoracic portion of the vertebral column is the most frequent seat of trauma causing concussion of the spinal cord. The trauma need not be direct. It may be transmitted from the vertex or from the sacral region. The earliest symptoms of concussion of the thoracic segment of the spinal cord frequently resemble those of a total physiologic severance of the cord with a complete flaccid motor and sensory paraplegia, urinary and fecal retention, abdominal distention, hematuria, edema of the lower extremities and bed sores. The course is as a rule favorable, with a transition from a flaccid to a spastic paraplegia. A fatal outcome in the course of a few weeks resulting from an infection from a bed sore or from bronchopneumonia, has been observed.

The simplest form of concussion of the cervical segment of the cord is that with a total loss of function of the spinal cord below the lesion. This concussion gives rise to a quadriplegia associated with anesthesia the upper limit of which corresponds to the lesion. There is retention of urine and feces, abdominal distention and respiratory difficulty if the lesion is sufficiently high. The symptoms may entirely disappear, although certain disturbances usually remain and give

rise to definite clinical types. Lhermitte¹ divides these somewhat schematically into the following groups: 1 Spastic quadriplegia, the paralysis being more pronounced in the upper extremities, associated further with sympathetic phenomena such as the Horner syndrome, with vasomotor, sweating, thermic and pilomotor disturbances. There exist as a rule spasticity and incoordination of the lower extremities, with sphincter and genital disturbances. 2 More frequently disappearance of the initial quadriplegia, which leaves in its place a form of spinal semiplegia with a more marked paralysis of an upper extremity, loss of sense of temperature of syringomyelic type and at times most excruciating pains in the upper extremity. 3 Brachial monoplegia associated with the Brown-Sequard syndrome and a rarer form of brachial diplegia. 4 Spastic cerebellar type, in which disturbances of coordination predominate over the paralytic phenomena. 5 "Formes frustes," a transient type which takes on a functional hysterical character and is characterized mainly by fatigue.

Cases have been observed in which there are bulbar symptoms, such as involvement of the muscles of the neck and the tongue and of sensory distribution of the trigeminal nerve.

Concussion of the lumbar segment is least frequent. It is accompanied by a flaccid paralysis of the lower extremities and involvement of the sphincters. Some time later there develop pathologic tendon reflexes and a positive Babinski reflex. The course is usually favorable, terminating not infrequently in a complete restoration of function.

Concussion of the spinal cord may give rise to clinical syndromes with predominantly sensory disturbances in which radicular pains, causalgic, hyperalgesic, shooting pains or heteresthesia may be present. Many observers believe the pathogenesis of these pains to be radicular. Lhermitte thinks they are due to loss of myelin sheaths of the intraspinal fibers, while the causalgic pains are due to lesions of the sympathetic fibers.

In a delayed form, symptoms appear hours, days or even weeks after the trauma. The nerve tissue lesions here are probably due to a progressive arteriopathy (Foerster).

The anatomopathologic changes in concussion of the cord were studied extensively during the World War. There may be small punctate or focal hemorrhages disseminated throughout the white substance or the gray matter, not however as extensive as those seen in hematomyelia. There is no blood in the cerebrospinal fluid. Small islands of focal necrosis disseminated in the white substance, and not always corresponding to the area of distribution of the blood vessel, constitute a more characteristic lesion. Some consider the primary acute degeneration of nerve fibers the most typical lesion in the condition. With proper staining, hypertrophy, thickening and change in form of the axis

¹ Lhermitte, Jean. Etude de la commotion de la moelle. *Rev. neurol.* 39: 210 (Feb.) 1932.

cylinders may be observed. Alterations of the myelin sheaths and a glial reaction are usually present. The spinal canal may be compressed or dilated. Radicular changes either of the hemorrhagic or of the primary degenerative type have been described.

Opinions regarding the pathogenesis of these lesions vary from that of a purely mechanical hypothesis of disturbed circulation, increased pressure in the cerebrospinal fluid and primary physicochemical changes in the cells and fibers of the nervous tissues to that of a hypothesis of cytotoxins developing as the result of trauma and causing more or less extensive softening of the cord.

Concussion of the spinal cord may be considered a definite clinical or at least an anatomical form of traumatic lesion of the spinal cord.

CHLOROPHYLL AND BLOOD REGENERATION

Years ago the suggestion was made¹ that chlorophyll, the green pigment of the leaves of plants, is similar chemically to the nonprotein portion of hemoglobin. Subsequent investigations have borne out this view and have demonstrated that both are composed of a nucleus of substituted pyrrol rings. As is well known the fundamental difference between the two pigments is that iron is present in hemoglobin whereas magnesium occurs in chlorophyll. The similarity of the two substances has prompted speculation regarding the possible value of chlorophyll as an agent for promoting blood formation. Animal experiments to test the possible existence of such a relation have yielded conflicting results. It has been stated² that rabbits rendered anemic by bleeding recover more rapidly if chlorophyll is added to the diet. Somewhat similar results have been obtained by several other investigators in rats³ and in dogs.⁴ Certain of these studies, however, were undoubtedly complicated by the presence of iron and perhaps other contaminants in the chlorophyll preparations used. In contrast to the foregoing favorable results, another group of investigators⁵ has found that green leafy plants are not especially effective in promoting hemoglobin formation in the chronic hemorrhagic anemia of dogs and have concluded that chlorophyll may be very like hemoglobin in its chemical structure but the normal dog cannot utilize much if any of the chlorophyll nucleus for hemoglobin construction even under maximal stress.⁶

Chlorophyll has likewise received some attention as a possible hematopoietic agent in man, and a claim has been made for its beneficial action.⁷ These results have been regarded with skepticism, however, since the preparation employed in the study contained only trivial amounts of chlorophyll.⁸ The most recent investigation of the effect of chlorophyll in human hematopoiesis⁹ was conducted on a group of fifteen adult patients with chronic hypochromic anemia. Chlorophyll and certain of its degradation products were administered to the patients with or without iron and the effect on the proportion of reticulocytes and concentration of hemoglobin and erythrocytes in the blood was closely followed. In all cases the oral administration of the chlorophyll preparations either alone or with small amounts of iron was entirely without effect. However, the administration of the test substances subsequent to the giving of larger amounts of iron produced a noticeable effect. There occurred a second reticulocyte response followed by a rise in the concentration of hemoglobin greater than that observed in the same patient with iron alone. Similar results were obtained when the materials were given parenterally thus indicating that the effect of the chlorophyll derivatives was not one of increasing the absorption of iron from the gastro-intestinal tract.

While further work is necessary before conclusions are drawn this investigation does suggest that, in the presence of adequate amounts of iron, the body may be able to use preformed pyrrol substances for the building of hemoglobin. However, as was stated,⁷ it should be emphasized that such substances are not recommended for therapeutic purposes, since iron therapy alone is an adequate treatment in most cases of uncomplicated chronic hypochromic anemia.

SEDIMENTATION RATE IN JUVENILE RHEUMATISM

Few recently introduced laboratory tests have been studied in relation to as wide a variety of clinical disorders as the so-called blood sedimentation test. In the rheumatic diseases, for example, most are agreed that the rate of erythrocyte sedimentation usually parallels closely the activity of the disease. Why this should be so, and why there are some notable exceptions, is still largely a matter of conjecture. Payne and Schlesinger¹ have recently reported further studies on the sedimentation rate in juvenile rheumatism.

They first divided their patients on a clinical basis (without reference to the test) into active and non-active cases. The criteria used were pulse rate, temperature, weight and cardiac signs, in doubtful

8 Payne W W and Schlesinger Bernard. *A Study of the Sedi-
mentation Rate in Juvenile Rheumatism* Arch Dis Childhood 10 403
(Dec) 1935

cases the cardiac signs were supplemented by the electrocardiogram. Two hundred and twenty-nine children were included in the study. An average of seven sedimentation tests was performed for each patient. One hundred and forty children were included in the nonactive group. Seventy-four of these had no signs of cardiac involvement and with three exceptions showed no rise in the sedimentation test apart from intercurrent infections. Sixty-six children had had heart disease at some time or other. In this group the sedimentation rate was normal in fifty-six and raised in ten (five for only a transitory period). Active rheumatism was present in eighty-nine cases. Sixty-six of these showed rapid improvement and were finally considered nonactive clinically. A corresponding fall to normal was shown by the sedimentation reaction in fifty-eight. In sixteen cases the activity was marked and prolonged. Here without exception the sedimentation rate was raised in close agreement with the clinical condition. In all but one of the seven fatal cases the sedimentation rate also was raised. They concluded, therefore, that it appears justifiable to regard the test as valuable in following the progress of rheumatic children with greater accuracy. Many other conditions, however, besides active rheumatism may increase the sedimentation rate, and some of these were the subject of further investigation.

Acute tonsillitis or nasopharyngitis generally produces a rise in the sedimentation rate. With few exceptions, chronic tonsillar sepsis does not affect the rate. Tuberculosis and rheumatoid arthritis both increase the sedimentation rate and both sometimes enter into the picture of juvenile rheumatism. In acute chorea, strangely enough, if any rise in the sedimentation rate occurs it is usually small and transitory. Congestive heart failure frequently results in a fall of the rate to normal even in the presence of active disease. There is further confirmation of this observation in another current study by Wood.² He found that congestive heart failure delays the sedimentation rate regardless of the pathologic changes in the heart. It thus follows that as an indication of the presence or absence of activity the sedimentation rate is a valueless measurement in cases of rheumatic carditis when complicated by congestive failure. Rapid rates are masked, and unless this fact is appreciated serious error in interpretation may occur. The effect of anemia also has been considered. The method of bringing the blood count to normal before performing the test is too cumbersome for routine use. Hence a graph showing the average normal value of the sedimentation rate at any known red cell count was constructed. By comparison of the red blood count, sedimentation rate and graph, apparently satisfactory corrections were readily obtained.

Current Comment

TOXIC EFFECTS OF SELENIUM

When attention was directed in January 1935 in these columns¹ to "the selenium problem," it was pointed out that this chemical element had been found in rather large amounts in certain grains and food plants and in soils obtained from several districts of South Dakota and the north central Great Plains area. Further, it was noted that the feeding of the selenium-containing foodstuffs to laboratory animals produced a train of symptoms resembling those of "alkali disease" of live stock foraging in affected areas. The urgent need for further work on selenium particularly with respect to the pathologic effects of the administration of this substance was stressed. Recently an investigation of this type has been reported.² The feeding of rats of a small amount of selenium as sodium selenite produced definite toxic symptoms similar to those observed in animals fed selenium-containing "toxic wheat." There was a distinct retardation of growth and an accompanying decrease in food intake. The latter effect was not due to an unpalatability of the diet, since a similar decrease in appetite was observed in animals injected with the salt. Pronounced alterations were observed also in the composition of the blood. After a preliminary rise in the concentration of hemoglobin, apparently resulting from an anhydremia, an anemia of progressively increasing severity developed. The erythrocytes of the anemic animals frequently showed achromia and later anisocytosis with polychromatophilic macrocytes. In acute cases there was a tendency toward leukopenia. Gross pathologic examinations at necropsy revealed evidence of extensive liver damage both in the animals which succumbed with acute toxic symptoms and in those which survived for a long time. The liver had a characteristic lobnailed appearance, resulting from local tissue necrosis followed by regeneration. A transudate was frequently present in the thorax or abdomen or both in those animals which died from the acute toxic effects of selenium. Similar evidence of pathologic changes in the liver has been obtained by another investigator,³ who noted also a frequent hypertrophy of the heart and spleen and an atrophy of the testes and uterus.

OPTOMETRISTS AND OPHTHALMOLOGISTS

The place of the optometrist in medical technique is, as every one knows, not yet fully established. From trends over the last quarter century it would seem that eventually optometry will become a technical specialty in medicine somewhat like that of those skilled in developing braces or crutches for other portions of the body. Optometry must be essentially a method of measurement of deficiency in muscular action or in construction of the eye with the adaptation of a crutch for the eye—the only thing that an eyeglass can really be. Never

theless it is well established that optometrists, like other technicians who have entered the field of medical practice, endeavor when once in the field to broaden out the scope of their activities and soon find themselves encroaching on the practice of medicine. The moment a person insufficiently trained expands beyond his limitations, he becomes a menace to those of the sick whom he attempts to treat. THE JOURNAL is moved to these comments by the observation of some literature recently developed by the Public Relations Committee of the Illinois State Society of Optometrists. The folders issued by this group are insidiously phrased to cause the public to believe that the optometrist is qualified far above physicians generally for the care of the eyes. Moreover, they attack the use of drugs for dilation of the pupil as a practice which is dangerous and unnecessary. The circular states falsely that optometrists are trained to recognize eye diseases. One finds, incidentally, that they are trained also in biology, psychology, sociology, economics and ethics. An observation of the circular would indicate that their training in at least one of these fields has been somewhat deficient. In general, ophthalmologists have not been greatly distressed by the work of the optometrist, since in many large communities there are optometrists who endeavor to practice their technical specialty with due regard for their limitations. If, however, the official organization of optometrists endeavors not only to expand the services beyond the limitation of optometric training but also, by insidious propaganda, to induce the public to have a false confidence in their qualifications, a situation must develop in which organized medicine will have to take definite action.

Association News

RADIO BROADCASTS

The American Medical Association broadcasts over WEAf, the Red network instead of the Blue as formerly and certain additional stations of the National Broadcasting Company at 5 p. m. eastern standard time (4 o'clock central standard time 3 o'clock mountain time 2 o'clock Pacific time) each Tuesday presenting a dramatized program with incidental music under the general theme of 'Medical Emergencies and How They Are Met'. The title of the program is 'Your Health'. The program is recognizable by a musical salutation through which the voice of the announcer offers the toast 'Ladies and gentlemen your health!'. The theme of the program is repeated each week in the opening announcement which informs the listener that the same medical knowledge and the same doctors that are mobilized for the meeting of grave medical emergencies are available in every community, day and night for the promotion of the health of the people. Each program will include a brief talk dealing with the central theme of the individual broadcast.

Red Network—The stations on the Red network of the National Broadcasting Company are WEAf WEEI WTIC, WJAR WTAG WCSH KYW WFBR WRC WGY, WBN WCAf WTAM WWJ WMAQ KSD WHO, WOW, WDAF.

Pacific Network—The stations on the Pacific network are KGO KPQ, KFI, KGW KOMO KHQ, KFSD KTAR.

Network programs are broadcast locally or rejected at the discretion of the local station. The lists indicate stations to which programs are available.

The next three programs are as follows:

March 17 Eyesight Saving W. W. Bauer M.D.
March 24 Hay Fever and Asthma Morris Fishbein M.D.
March 31 Let Your Doctor Decide W. W. Bauer M.D.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ALABAMA

Bill Introduced—H. 221-X proposes to require the payment annually to the board of health of Mobile County, out of the general county fund of such money as is reasonably necessary for the maintenance and operation of a county health department, not less than 15 cents per capita.

CALIFORNIA

Medical Board Reappointed—The following members of the California Board of Medical Examiners have been reappointed: Drs. Harry V. Brown, Glendale; William R. Molony, Los Angeles; Fred R. DeLappe, Modesto; and Charles B. Pinkham, San Francisco. Dr. Frederick W. Didier, Wheatland, has been appointed to succeed the late Dr. Percy T. Phillips, Santa Cruz.

Society News—The San Francisco County Medical Society was addressed March 10 by Drs. Robert R. Newell and Eric Liljencrantz on "Usefulness of Roentgen Therapy in Inflammatory Processes" and 'Carcinoma of the Breast—Rationale of Treatment' respectively. At a meeting of the Los Angeles Society of Neurology and Psychiatry, March 18, Drs. Walter F. Schaller, San Francisco, will discuss "The Nature of Petechial Hemorrhages in Traumatized Brains" and Eberle Kost Shelton, Santa Barbara, "The Psychologic Aspects of Physiologic Imbalance." A symposium on appendicitis was presented before the surgical section of the Los Angeles County Medical Association, March 13 by Drs. Fred R. Fairchild, Woodland; John W. Budd, Jr., Clarence G. Toland, Charles E. Phillips, Los Angeles, and Arthur Dean Bevan, Chicago.

COLORADO

Society News—At a meeting of the Larimer County Medical Society in Loveland, February 5, Drs. James B. Walton, Denver, discussed problems of the new-born, and Gerrit Heusinkveld, Denver, obstetrics. The Northeast Colorado County Medical Society was addressed in Sterling, February 13, by Drs. Chesmore Eastlake on 'Differential Diagnosis of Influenza' and Philip Work, 'What the Patient Calls Nervousness'. Both are from Denver. Dr. Royal C. Adkinson, Florence, discussed hyperinsulinism before the Fremont County Medical Society in Canon City, January 27. Dr. Edwin D. Burkhardt read a paper entitled 'A Medical Survey of 1935' before the Pueblo County Medical Society, January 21.

Cragmor Sanatorium Reorganized—Cragmor Sanatorium, at the foot of Austin bluffs northeast of Colorado Springs, has been incorporated under the laws of the state as a 'non-profit, nonsectarian organization created for benevolent charitable and humanitarian purposes and for the treatment of tuberculosis and other ailments' as well as for research work. A board of directors of five members and an advisory board of trustees will govern the new association, through the ratification of an agreement between the old company, the bondholders' committee and certain individuals. The sanatorium was founded in 1906 by Dr. Edwin S. Solly with accommodations for twenty-five patients. Situated on 240 acres of land, the sanatorium now has a bed capacity of 130. The entire institution, valued at about \$500,000, is made up of a main building accommodating fifty-two patients, a two-story building for twenty patients, a home building with twenty-two beds, a women's cottage of eight beds, a men's cottage of eight beds, nine cabins and one other small unit of eight beds. Adjoining the sanatorium is Cragmor Village consisting of twenty-seven cottages five of which are owned by the sanatorium and the others by persons who have been permitted to erect their own cottages on the sanatorium grounds. In addition there is a large four-story cement building which was formerly used as a nurses home. Dr. Alexius M. Forster has been physician-in-chief at the institution since 1910.

DELAWARE

Society News—Dr. Jesse O. Arnold, Philadelphia, presented a paper before the New Castle County Medical Society in Wilmington, January 21, entitled 'Revising the Code of Prenatal Care'. Dr. John T. King, Baltimore, addressed the society, February 18.

DISTRICT OF COLUMBIA

Medical Bill in Congress—S 4166, introduced by Senator Bulow, South Dakota, provides that the compensation of interns and student nurses who are subject to the Classification Act of 1923, serving in government hospitals located in the District of Columbia, may be fixed by the Civil Service Commission without regard to the compensation schedules contained in the Classification Act.

Protest Curtailment of Health Budget—At a public meeting in Washington, called by the Medical Society of the District of Columbia, February 16, resolutions were adopted protesting the curtailment of the budget for health work in the district for the fiscal year 1936-1937. In a statement read by Dr. Prentiss Willson, chairman of the committee on program and resolutions, it was pointed out that the per capita expenditure for public health is far below standard, that the health department lacks adequate space, personnel and equipment to carry on its work efficiently, that provisions for the care of venereal disease at the municipal clinics are hopelessly inadequate and that too few nurses are employed at Gallinger Municipal Hospital and the Children's Tuberculosis Sanatorium at Glenn Dale, Md. Members of the Medical Society of the District of Columbia and representatives of other health agencies and lay organizations attended the meeting. Speakers included Rabbi Abram Simon, who presided; Dr. Sterling Ruffin, president of the medical society; Dr. Herbert P. Ramsey, Dr. Harry Stoll Mustard, Baltimore; and Rev. John O'Grady, director of Catholic Charities for the district. Representative Thomas L. Blanton of Texas, chairman of the House subcommittee on district appropriations, was present.

FLORIDA

Society News—At a meeting of the Tri-County Medical Society (DeSoto-Hardee-Highlands) in Sebring, February 11, Drs. Joe M. Bosworth, Lakeland, discussed 'The Use of the McBurney Incision' and Hartley E. Boorum, Sebring, 'Narcoplexy'.—Dr. Harry A. Peyton, Jacksonville, read a paper on 'Cancer of the Small Intestine' before the Duval County Medical Society in Jacksonville, February 4.—At a meeting of the Leon-Gadsden-Liberty-Wakulla-Jefferson County Medical Society in Quincy, January 16, speakers included Drs. Harry B. McEuen, Jacksonville, treatment of an extensive carcinoma with lantern slide and color motion picture demonstration of the results; William W. Massey, Quincy, a review of the modern treatment of burns; Courtland D. Whitaker, Marianna, acute coronary thrombosis; and Ralph M. Clements, Chattahoochee, conditions affecting the eye, ear, nose and throat.—Dr. George R. Creekmore, Brooksville, read a paper before the Pasco-Hernando-Citrus County Medical Society at its meeting in Brooksville, January 9, entitled 'Thigh Amputations'.

ILLINOIS

Society News—Mr. Harold Baker, East St. Louis, discussed 'The Harrison Narcotic Act' before the St. Clair County Medical Society in East St. Louis, March 5. Speakers at the March 4 meeting in Belleville included Drs. Robert S. Berghoff and Clayton J. Lundy, Chicago, on 'Diagnosis and Treatment of Heart Disease' and 'Electrocardiogram in Early Diagnosis of Arteriosclerotic Heart Disease' respectively.—At a meeting of the LaSalle County Medical Society in LaSalle, February 26, speakers were Drs. Edward A. Rohing, Chicago, on 'Eye Conditions of Interest to the General Practitioner', Tell Nelson, Chicago, 'Diagnosis of Allergic Conditions', and Edward G. Tatge, Evanston, 'Allergy in General Practice'.—Dr. Chauncey C. Maher, Chicago, discussed 'Hypertensive Vascular Disease' before the Adams County Medical Society in Quincy, March 9.

Chicago

Ranson Lecture—Dr. Hugh Cabot, Rochester, Minn., delivered the eighth annual Stephen Walter Ranson Lecture at Northwestern University School of Medicine, February 25, on 'The Changing Practice of Medicine'.

Increase in Heart Disease—In 1935 there were 10,085 deaths attributed to heart disease as compared with 9,654 in 1934. These totals, based on statistics reported by the Chicago Heart Association, compare with 35,424 deaths from all causes in 1935 and 36,282 in 1934.

Hospital News—Cook County Hospital cared for 69,891 patients during 1935, although the normal daily capacity of the hospital is 2,600, a daily average of 2,619 was maintained by placing beds in hallways and opening two new floors in the children's ward which provided 190 additional beds. The

number of persons who died in the hospital was 6,650. There were 82,721 patients turned away from the hospital, of the 25,284 received first aid treatment.

Society News—Dr. Anton J. Carlson gave an address at a meeting of the Cook County League of Women Voters in the Palmer House, March 14, entitled 'Buyers Beware! The New Food and Drug Act. A Test in Consumer Effectiveness'.—Speakers before the Chicago Gynecological Society, March 20, will include among others, Drs. George H. Rezek, on 'A Biological Test for the Diagnosis of Intra-Uterine Fetal Death' and Harold H. Hill, Oak Park, 'Value of the Sturmdorff Cone for Biopsy Material in the Detection of Early Carcinoma of the Cervix Uteri'.

Hospital Council Formed—The Chicago Hospital Council was recently organized to work out a program of group hospital insurance, newspapers report. Hospitals that have joined the council are Augustana, Berwyn, Garfield Park Community, Bethany, Grant, Henrotin, Holy Cross, Home for Destitute Crippled Children, St. Anthony de Padua, Little Company of Mary, Lutheran Deaconess, Michael Reese, Mount Sinai, St. Bernard's, St. Joseph, St. Luke's, University of Chicago Clinics, including Billings Memorial, Bobs Roberts Memorial and the Max Epstein clinics, Women's and Children's Hospital, and Woodlawn.

Survey of Visual Conditions—A survey of visual conditions in public schools in Chicago is under way under the auspices of the board of education, as a project of the works progress administration. The eyesight of all children will be tested. The Illinois Society for the Prevention of Blindness is supervising the making of the tests. Children whose vision falls below 20/70 will be required to have an examination by an ophthalmologist. Members of the Chicago Ophthalmological Society who will assist in making the examinations are requested to consider this work as a partial charity since it is primarily for the underprivileged. Rates have been fixed for patients able to pay a fee, and free choice of physician is urged.

INDIANA

Fifty Years of Practice—Dr. Walter N. Thompson, Sullivan, was guest of honor at a banquet given by the Sullivan County Medical Society, February 14, to observe his completion of fifty years in the practice of medicine. All in Sullivan, Dr. Jacob T. Oliphant, Farmersburg, was master of ceremonies, and speakers included Drs. James B. Maple, Sullivan, Arthur F. Weyerbacher and Willis D. Gatch, Indianapolis. Dr. Joseph R. Crowder presented Dr. Thompson with a picture of the county medical society and a gold wrist watch engraved with the following: 'Presented to Dr. Walter N. Thompson by the Sullivan County Medical Society in honor of fifty years of service, February 16, 1936. Dr. Thompson's father, Dr. J. J. Thompson, practiced fifty years and six months in Sullivan'.

Society News—Dr. Willis D. Gatch, Indianapolis, discussed cancer before the Muncie Academy of Medicine, February 11.—At a meeting of the Hamilton County Medical Society in Cicero, February 11, Dr. Marlow W. Manion, Indianapolis, spoke on 'Laryngeal Obstruction'.—The Putnam County Medical Society was addressed in Greencastle, February 11, by Dr. James O. Ritchey, Indianapolis, on 'Non-tuberculous Chest Infections'.—At a meeting of the Parke Vermillion County Medical Society in Clinton, February 19, Dr. George S. Bond, Indianapolis, discussed 'Diseases of the Coronary Arteries'.—Dr. Harold D. Lynch, Evansville, spoke on communicable diseases before the Knox County Medical Society in Vincennes, February 11.—Dr. Fred Bierly, Jr., Elkhart, discussed high and low blood pressure before the Floyd County Medical Society in New Albany, February 14.—The Tippecanoe County Medical Society was addressed in Lafayette, March 10, by Dr. Delbert O. Kearby, Indianapolis, on 'Bronchoscopy, Better Diagnosis and Treatment of Bronchial Disturbances'.—Dr. Mason B. Light read a paper on 'Endoscopy in the Diagnosis and Treatment of the Food and Air Passages' before the Indianapolis Medical Society, February 25.

KANSAS

Course in Neuropsychiatry—A graduate course on neuropsychiatry in general practice will be held at the Menninger Clinic, Topeka, April 20-25. The course will be directed to the application of modern neuropsychiatric principles to cases which the general practitioner frequently sees in this field. Enrollment in the course is limited to thirty. In addition to members of the Menninger Clinic, guest lecturers will be Drs. Israel S. Wechsler, New York, and James W. Kernohan, Rochester, Minn.

MASSACHUSETTS

Personal—Dr William B Keeler, newly appointed health commissioner of Boston, was guest of honor at a dinner at the Myles Standish Hotel, January 29. Dr Charles I Winksky acted as host and toastmaster.—A farewell dinner was given to Dr Karl M Bowman, formerly chief medical officer of the Boston Psychopathic Hospital, January 30 by about 100 friends and associates. Dr Bowman has been named director of the psychiatric division of Bellevue Hospital New York.

MICHIGAN

Koch Loses Malpractice Suit—A verdict for \$5,500 was returned by a jury in the circuit court of Wayne County, January 24, in a malpractice suit instituted against William F Koch, director of the Koch Cancer Foundation by Alfred A Fortner, a former patient. This case was a retrial of a former proceeding in which a verdict was rendered against Koch for \$25,000, reduced by the trial court to \$7,000. The supreme court of Michigan on an appeal by Koch reversed the judgment for certain errors committed by the trial court and ordered a new trial (THE JOURNAL, February 22, p 651). According to the newspapers, Fortner alleged that Koch charged him \$300 each for injections of a cancer serum when he was not suffering from cancer. He claims to have gone to Koch believing he had cancer and was treated with the serum from June to September 1931, after which Koch advised him to discontinue the treatment and go to a hospital. Fortner then discovered he had another disease. The complaint charged Koch with negligence. Koch graduated from the Detroit College of Medicine and Surgery in 1918. Less than a year after his graduation in medicine, he announced that he had developed a cure for cancer. In 1921 he was dropped from membership in the Wayne County Medical Society for exploiting a so called cancer cure (THE JOURNAL, May 8, 1926, p 1469; July 14 1934, p 116).

MINNESOTA

Society News—Speakers before the Hennepin County Medical Society March 11 were Drs Herbert A Burns Ah-Gwah-Chung, on "Indian Medicine" and Arthur C Kerkhof Minneapolis, "The Gastroscope".—At a meeting of the Minnesota Academy of Medicine, March 11, speakers were Drs Louis A Buie, Rochester on "Ancient and Modern Knowledge Concerning Anal Fistula" and Charles B Wright, Minneapolis, "Multiple Myeloma and Its Differential Diagnosis".

Minneapolis Children Free from Malnutrition—There is practically no malnutrition evident among children in the Minneapolis public schools, according to Dr Francis E Harrington, director of hygiene. A general observation survey of the school children was made during the period from September to the Christmas holidays to determine as near as possible their nutritional status. There are occasional cases of undernourishment but the percentage in the school system is less than was found five years ago. The children appear, as a rule, to be having better home care. These facts are supported by reports from physicians throughout the city, child agencies and the children's wards at the Minneapolis General Hospital. In all instances, it was stated, malnutrition has apparently decreased.

MISSISSIPPI

Bill Passed—H 289 has passed the house proposing to enact what appears to be the uniform narcotic drug act for the regulation of the manufacture, sale, possession, prescribing, administering, dispensing, compounding and cultivating of narcotic drugs. The bill defines narcotic drugs as meaning coca leaves, opium, cannabis and every substance neither chemically nor physically distinguishable from them.

Bills Introduced—H 540 proposes to regulate the practice of chiroprody or podiatry and to authorize the state board of medical examiners to examine and license applicants for such licenses. The bill defines chiroprody or podiatry as the diagnosis and medical, mechanical, electrical, and surgical treatment of the minor ailments of the human foot, such as corns, callouses, warts, ingrowing and abnormal nails, bunions and similar conditions. Licentates are to be allowed to use such mechanical appliances as may be deemed necessary for the relief or cure of ailments of the feet. Amputation of the foot or of toes and the use of anesthetics other than local are apparently prohibited but the language of the bill in this connection is obscure. Diseases and conditions of the feet produced by kidney, heart or other systemic diseases are not to be treated by a chiroprodist or podiatrist except under the direction of a regularly licensed physician. H 422, to amend the dental prac-

tice act, proposes to authorize the revocation of the license of any licentiate advertising professional superiority or the performance of professional service in a superior manner, advertising prices for professional service, advertising by means of large display glaring light sign or containing as a part thereof the representation of a tooth, teeth, bridge work or any portion of the human head, or employing advertising solicitors or free publicity press agents, advertising any free dental work or free examination, advertising to guarantee any dental service or to perform any dental operation painlessly, or advertising any commercial dental laboratory or clinic, either pay or free when it is operated in connection with the practice of a licensed dentist or dental hygienist.

MISSOURI

Society Memberships Presented to Interns—At a recent meeting the staff of the DePaul Hospital, St. Louis presented a junior membership in the St. Louis Medical Society to each intern connected with the hospital. The *Journal of the Missouri Medical Association* compliments the hospital staff for this action.

NEW JERSEY

Society News—Dr Oliver Spurgeon English, Philadelphia addressed the Burlington County Medical Society, Moorestown, January 9, on management of the neurotic patient.—Dr Joseph C Doane, Philadelphia, addressed the Cape May County Medical Society, January 14, on "The Autonomic Nervous System in General Practice".—Dr Walter E Dandy, Baltimore, addressed the Academy of Medicine of Northern New Jersey Newark, February 20, on "Treatment of Injuries of the Head".—At a meeting of the Monmouth County Medical Society January 6, Dr William P Thompson, New York, spoke on splenomegaly.—Dr Philip F Williams, Philadelphia, addressed the Essex County Medical Society, March 12, on "Intrapartum Care in Its Relation to Maternal Welfare".

NEW YORK

Dr Cheney Appointed in Charge of Bloomingdale Hospital—Dr Clarence O Cheney, director of the New York Psychiatric Institute and Hospital at the Columbia University Medical Center, has been appointed superintendent and director of the Bloomingdale Hospital, White Plains, succeeding the late Dr Mortimer W Raynor. For five years prior to his appointment at the New York Psychiatric Institute and Hospital in 1931, Dr Cheney had been director of the Hudson River State Hospital, Poughkeepsie. He was secretary of the American Psychiatric Association from 1928 to 1933 and is now president of the organization. When the association established a certification board in 1933 Dr Cheney was named its first chairman. He will continue in his present position until the end of the present fiscal year June 30.

Bills Introduced—S 1259 to amend the public welfare law in relation to the manner of providing medical care to indigents, proposes to require the appropriate public welfare official to provide medical care for the indigent sick in their homes and to permit the patient to be attended by his family physician or other physician of his own choice. S 1341 proposes to prohibit any person who conducts a retail store for the sale of footwear and who accepts orders for footwear to fit abnormal feet from accepting such orders except on the prescription of registered podiatrists. S 1389, to amend the medical practice act, proposes to authorize the revocation of the license of a physician who (1) has employed, hired, procured or induced an unlicensed person to practice medicine, (2) who has aided or abetted in the practice of medicine a person who is not licensed so to practice, or (3) who has advertised for patronage, by means of handbills, posters, circulars, stereopticon slides, motion pictures, radio, newspapers or magazines. S 1393 proposes to require the board of regents of the University of the State of New York, prior to Jan 1, 1937, to establish and appoint a state board of chiropractic examiners. This board after its organization would establish rules and regulations fixing the qualifications of applicants for licenses to practice chiropractic, the examination of such applicants, and the granting and issuing of licenses to practice chiropractic. The bill proposes to define chiropractic, in effect, as the adjustment of the human skeletal frame according to the doctrine of chiropractic. Such practice is not to include the performance of surgical operations with the use of instruments or the prescribing or use of drugs or medicines but x-rays may be used for the purpose of examination. S 1404 and A 1690, to amend the narcotic drug act, proposes to define 'wholesaler' as 'a

person who supplies others than consumers with narcotic drugs or preparations containing narcotic drugs that he himself has not produced or prepared." S 1416 proposes to require every physician attending any person whom he believes suffering from poisoning by lead, phosphorus, arsenic, brass, wood alcohol, mercury or other compounds, or from anthrax, or compressed air illness, or from any occupational disease contracted as the result of the nature of such person's employment, to report the facts to the industrial commissioner. A 1510, to amend the medical practice act, proposes to require applicants for licenses to practice medicine to be citizens of the United States. The present law merely requires an applicant to have declared his intention of becoming a citizen. A 1511, to amend the medical practice act, proposes that "notwithstanding the provisions of the act or of any other general or special law, no license or certificate, wherever issued, shall be endorsed without examination as a license to practice medicine in New York unless the holder thereof shall have graduated from a medical school or college registered as maintaining at the time a standard satisfactory to the [education] department. A 1683 proposes to prohibit the sale or possession with intent to sell, of any inaccurate clinical thermometer, defined as "every thermometer intended for taking the temperature of human beings and animals." A clinical thermometer is to be deemed to be inaccurate (a) if, when tested with a standard clinical thermometer, the mercury fails to register within plus or minus two tenths of a degree Fahrenheit, (b) if the mercury column, by reason of its own weight, or for any reason other than through the application of force, retreats in the tube at any point in the scale, (c) if the scale fails to show accurately, clearly and legibly, graduation lines and numbers from 96 to 106 degrees Fahrenheit or (d) if the maker's name or trademark is not clearly and legibly engraved thereon or where the trademark appears thereon, such trademark has not been filed with the department of health.

New York City

Sixth Harvey Lecture—Dr Richard E. Shope of the Department of Animal and Plant Pathology, Rockefeller Institute for Medical Research, Princeton, N. J. will deliver the sixth Harvey Lecture at the New York Academy of Medicine March 19. His subject will be "Influenzas of Swine and Men." The seventh lecture will be given by Dr Warren H. Lewis, Baltimore, professor of physiologic anatomy and research associate, Carnegie Institution of Washington, April 16, on "Malignant Cells."

Blizzard Class Reunion—The forty-eighth reunion of the so-called Blizzard Class, which graduated from Bellevue Hospital Medical College on the night of the famous blizzard of March 12, 1888, was held at Cavanagh's Restaurant March 12. Of 144 members of the class, twenty-five who responded to the invitation seemed to be still in practice. It was reported. According to *New York Medical Week* the "Blizzard Men of 1888" an organization of professional and business men, was to meet at a luncheon at the Hotel Pennsylvania for a reunion on the anniversary date. The *New England Journal of Medicine* announces that Dr Samuel M. Strong, 4233 Kissena Boulevard Flushing is interested in compiling experiences of the famous storm and hopes that physicians will send their accounts to him.

NORTH CAROLINA

Report of the Duke Endowment—The tenth annual report of the hospital section of the Duke Endowment reveals that \$5,828,048 has been given to 141 hospitals in North and South Carolina for free bed days in the last ten years, assistance was given to 51 per cent of the 908,099 inpatients treated in these institutions. The endowment contributed 30 per cent of the cost of free service in these hospitals and provided the equivalent of the total cost of free service for 480 patients daily since aid in this field was begun. During the ten years it paid at the actual average cost of \$39.40 per patient the full cost of treatment of 147,880 patients, and built and equipped sixty-two hospitals in the Carolinas at a cost of \$2,371,791.72. Contributions from the Duke Endowment to the Carolina hospitals constituted 33.6 per cent of the contributions from all sources for the ten year period. The average daily per capita cost over the period was for all hospitals \$3.56, hospitals for white patients, \$4.16, hospitals caring for both races, \$3.57, hospitals for Negroes \$1.90. The report points out that privately operated hospitals in the Carolinas decreased from ninety-three to forty-five in the ten year period while nonprofit or public hospitals increased from forty-seven to 112. In 1924 51.2 per cent of all general hospital beds were privately operated and in 1934 only 16.7 per cent were on this basis.

OHIO

Founders' Day at State University—The annual Founders' Day program of the Ohio State University College of Medicine, Columbus, was held March 6-7. Clinics at St. Francis and University hospitals occupied the first morning. In the afternoon there was a symposium on virus diseases presented by Dr. Noel Paul Hudson, F. S. Markham, W. A. Starn, Ph.D., J. M. Birkeland and Dr. Oram C. Woolpert. In the evening Dr. Carl V. Weller, professor of pathology, University of Michigan Medical School, Ann Arbor, delivered the Alpha Omega Alpha lecture, on "Anthony van Leeuwenhoek and His Microscopes." Saturday morning addresses were made by Drs. Russell L. Haden, Cleveland, on "Mechanisms of Anemia," Gatewood, Chicago, "History of Surgery," and Martin H. Fischer, Cincinnati, "Diabetes."

PENNSYLVANIA

Society News—Dr. Dean D. Lewis, Baltimore, addressed the Erie County Medical Society, Erie, February 11, on "Endothelial Tumors."—Dr. William H. Guy, Pittsburgh, conducted a clinic for the Fayette County Medical Society, Umontown, March 12, on diagnosis and treatment of skin diseases.—A symposium on the eye, ear, nose and throat was presented at a meeting of the Dauphin County Medical Society, Harrisburg, February 4, participants were Drs. Jay D. Smith, George H. Seaks, Harold F. Lanshe and Byron B. Bobb.—Dr. William L. Mullins, Pittsburgh, addressed the Harrisburg Academy of Medicine, February 18, on coronary occlusion.

Philadelphia

Changes at Temple University—The departments of neurology and neurosurgery at Temple University School of Medicine have been combined with Dr. Temple Fay, professor of neurosurgery, as head of the department, and Dr. James W. McConnell, associate professor of neurology, Graduate School of Medicine of the University of Pennsylvania, as professor of neurology. The department of pathology has been completely reorganized under the direction of Dr. Lawrence Weld Smith. Promotions include that of Dr. Edward Weiss from clinical professor to professor of clinical medicine.

Pittsburgh

Society News—Speakers at a meeting of the Allegheny County Medical Society, February 18, were Drs. J. West Mitchell on "Vascular Diseases of the Extremities," John P. Henry "Injection Treatment of Varicose Veins," and S. Benjamin Meyers, Johnstown, "Frigidity—A Problem in General Practice."—Dr. Otto H. Schwarz, St. Louis, addressed the Pittsburgh Society for Biological Research, February 20, on "Puerperal Infection."—Speakers at the meeting of the Pittsburgh Academy of Medicine, February 25, were Drs. Samuel R. Haythorn, on "The Present Status of Pneumococcosis," and Harold A. Kipp "Factors Influencing the Variations in Pressure in the Biliary Tract."

TEXAS

Society News—Drs. Emmett O. Rushing and Calvin R. Hannah addressed the Dallas County Medical Society, February 13, on "Everyday Clinical Points in Classifying the Three Types of Gonorhea" and "Prevention and Treatment of Puerperal Infection" respectively.—Dr. John L. Burgess, Waco, addressed the Bosque County Medical Society, Clifton, January 16, on otolaryngology for the general practitioner.—Drs. Khleber H. Beall and Samuel Jagoda, Fort Worth, addressed the Cooke County Medical Society, Gainesville, January 14, on "Coronary Occlusion" and "The Electrocardiograph as a Diagnostic Aid" respectively.—Dr. Henry M. Winans, Dallas, discussed "Recent Contributions to the Knowledge of Heart Disease" as guest of the Navarro County Medical Society, January 6.

VIRGINIA

Bill Passed—S. 289 has passed the senate and the house proposing to prohibit the possession, sale, use, distribution or production of cannabis. Nothing in the bill, however, is to be construed as applying to licensed growers, licensed manufacturers of drugs and medicinal supplies, hospitals, registered wholesale and retail pharmacists or to licensed physicians, dentists and veterinarians.

Health at Richmond—Telegraphic reports to the U. S. Department of Commerce from eighty-six cities with a total population of 37 million, for the week ended February 29, indicate that the highest mortality rate (24.7) appeared for Richmond and that the rate for the group of cities was 14.8. The

rate for Richmond for the corresponding week of 1935 was 168 and for the group of cities, 132. The annual rate for the eighty-six cities for the nine weeks of 1936 was 137 as compared with 113 for the corresponding period of 1935. Caution should be used in the interpretation of these weekly figures, as they fluctuate widely. The fact that a city is a hospital center for a large area or that it has a large Negro population may tend to increase the death rate.

PHILIPPINE ISLANDS

Medical Society Election—Officers of the Philippine Islands Medical Association elected at the annual meeting are Drs. Rufino Abriol, Manila, president, Ramon F. Campos, Iloilo, and Juanario R. Estrada, Manila, vice presidents, and Antonio S. Fernando, Manila, secretary.

PUERTO RICO

Society News—At a meeting of the Puerto Rico chapter of the Pan American Medical Association recently Dr. Isaac F. Gonzalez Martinez was elected president, Dr. Jose Rodriguez Pastor, vice president, and Dr. Rafael Rodriguez Molina, secretary, reelected. All are from San Juan.

GENERAL

Journal for Interns—The first issue of the *American Internist* appeared in January. It is a twenty-eight page magazine edited by Harold Salkin and published independently in New York. The first issue contained short scientific articles, editorials, book reviews and an open forum.

Tri-State Meeting—Dr. Douglas Jennings, Bennettsville, S. C., was elected president of the Tri-State Medical Association of the Carolinas and Virginia at its annual meeting in Columbia, S. C., February 17-18. The 1937 meeting will be held in Norfolk, Va. Guest speakers included Drs. Edward J. G. Beardsley, Philadelphia, on 'What Life Teaches the Doctor' and 'Common Sense in Cardiac Diagnosis' and Page O. Northington, New York, 'Upper Respiratory Infections'.

Educational Films to Be Listed—The U. S. Office of Education and the American Council on Education are making a survey to list all motion pictures that have an educational value. The survey is part of the council's work toward establishment of a national educational film institute to develop use of the motion picture and other allied visual-auditory aids in all fields of learning. Any person or organization that has produced, now owns or has the exclusive distribution rights to any motion picture that should be included in the catalogue is asked to send for film catalogue cards from the American Council on Education, 744 Jackson Place, Washington, D. C.

Southern Assembly—Dr. Robert M. Adams, Ripley, Miss., was chosen president elect of the Mid-South Post Graduate Medical Assembly at the fifty-second annual session in Memphis, Tenn., February 11-14. Dr. Carl R. Crutchfield, Nashville, was installed as president. Among guest speakers were:

Dr. Conrad Berens, New York, 'External and Ophthalmoscopic Examination of the Eye with Reference to Treatment of Underlying Diseases';
Dr. Claude S. Beck, Cleveland, 'The Heart as a Surgical Organ';
Dr. Frank H. Jaffe, Boston, 'Indications for Surgery and Surgical Management of Gastric Lesions';
Dr. Richard H. Jaffe, Chicago, 'Differential Diagnosis of Leukemia';
Dr. Henry Norman Bethune, Montreal, 'Surgery of the Chest';
Dr. Eugene M. Landis, Philadelphia, 'Diagnosis and Treatment of Peripheral Vascular Disease';
Dr. Emil Novak, Baltimore, 'Endocrinology of the Female Reproductive Cycle'.

News of Epidemics—About 110 cases of meningitis with thirty deaths in Harlan County, Ky., led health officers to close theaters and restrict public gatherings throughout the county, newspapers reported March 7. Schools, theaters and other places of public assembly were closed in Bowie County, Texas, where nine deaths from meningitis have recently occurred, it was reported February 27, at the same time an epidemic of influenza caused most of the schools in Jefferson County, Texas, including those in Port Arthur, to be closed. Schools and theaters at Richlands, W. Va., and vicinity were placed under quarantine February 3, when six cases of meningitis were reported. Four cases of meningitis with one death were reported from small towns near Allentown, Pa., February 10. Two cases of meningitis were reported aboard the navy training ship *California State*, February 10. Sixty-two cases of scarlet fever among inmates and employees of the Rockland State Hospital, Orangeburg, N. Y., were reported February 16. Epidemics of mumps affecting 200 school children in Greensburg, Pa., and sixty in a grade school in Lebanon County, Pa., were reported in February.

Medical Bills in Congress—Changes in Status S. 2625 has been reported to the House, proposing to extend the facilities of the United States Public Health Service to seamen on government vessels not in the military or naval establishments. H. R. 3629 has been reported to the House, proposing to authorize the acquisition of additional land for the use of the Walter Reed General Hospital. H. R. 5764 has been reported to the Senate, proposing to compensate Dr. Augustus J. O'Brien and the Grand View Hospital, Ironwood, Mich., for services rendered in connection with the treatment of persons injured by federal agents during the Dillinger raid on the Little Bohemia Lodge, Manitowish Wisconsin. H. R. 10630, making appropriations for the Department of the Interior for the fiscal year ending June 30, 1937, has passed the House and Senate. As passed by the House, the bill authorized the Bureau of Mines to sell helium to hospitals and members of the medical profession for the treatment of disease, subject to the approval of the United States Public Health Service. The Senate struck this authorization from the bill. **Bills Introduced** S. Cou. Res. 34 introduced by Senator Murray, Montana, proposes to create a joint congressional committee to make an investigation of the conditions in the metal miners' occupation with particular reference to silicosis and tuberculosis. H. Res. 429, introduced by Representative Connerly, Massachusetts, proposes to authorize the Committee on Labor, as a whole or by a subcommittee, to investigate the health conditions of workers employed in the construction and maintenance of mining and tunneling projects, with particular reference to silicosis and other respiratory diseases. S. 4033, introduced by Senator Schwellenbach, Washington, proposes to amend the Longshoremen's and Harbor Workers' Compensation Act so as to provide that the medical and surgical care rendered under the act "shall include attendance and treatment by any physician or surgeon selected by the injured employee who resides in the same community with the injured employee and whose competency has been approved by the deputy commissioner, if the employee is not satisfied with the physician or surgeon selected by the employer." S. 4059, introduced by Senator Copeland, New York, proposes to provide medals of honor for civilian government employees for distinguished service. S. 4153, introduced by Senator Bone, Washington, proposes to provide hospitalization for certain employees in the Bureau of Navigation and Steamboat Inspection of the Department of Commerce and for licensed local pilots of the United States. S. 4181 introduced by Senator McAdoo, California, proposes to authorize an appropriation of \$375,000 to construct a new wing on the veterans' hospital at Los Angeles. H. Res. 432 introduced by Representative Daly, Pennsylvania, proposes to request the Secretary of the Navy and the Administrator of Veterans' Affairs to submit a report respecting the Naval Hospital at Philadelphia setting forth the facilities at the hospital, the extent of its use by veterans, its needs for additional facilities, and certain other relevant facts. H. J. Res. 496, introduced by Representative Randolph, West Virginia, proposes to erect a memorial to Dr. Samuel Alexander Mudd for his "heroic and invaluable medical aid to yellow fever victims." Dr. Mudd gave medical aid to the assassin of President Lincoln and was sentenced to life imprisonment at Fort Jefferson. Subsequently he received a complete and unconditional pardon. The services for which it is proposed to give recognition were rendered 'to his fellow men while being held a prisoner for a crime which he did not commit.' H. R. 11330, introduced by Representative Gassaway, Oklahoma, proposes to authorize the dissemination of information relating to the prevention of conception and articles designed adapted or intended for the prevention of conception, when sent, carried or conveyed (1) to licensed physicians for the treatment of patients (2) to licensed druggists for the purpose of filling prescriptions (3) to any legally chartered medical school for medical instruction at such school, or (4) to any legally licensed or chartered hospital or clinic for the treatment of patients in such hospital or clinic.

CANADA

Lawyer Appointed Minister of Pensions and Health—Charles G. Power, Quebec, a lawyer and a member of Parliament at various times since 1917, has been appointed minister of pensions and national health for Canada. The new minister was born in Quebec and educated in law at Laval University. He received the Military Cross for distinguished service overseas during the World War.

Society News—Drs. Walter M. Paton and Bede J. M. Harrison addressed the Vancouver Medical Association, January 7, on 'Tumors of the Head and Neck' and 'Roentgenology of Cardiac Diseases' respectively. Mr. J. W. deB. Farris

discussed medicolegal problems before the association, February 4—Dr Akiah H. Gordon, Montreal discussed 'Bone Changes in Certain Medical Diseases' before the Academy of Medicine of Toronto, February 4

LATIN AMERICA

Society News—The National Academy of Medicine of Mexico recently elected the following officers: Drs Gustavo Baz, president; Ignacio Gonzalez Guzman, vice president; Alfonso Pruneda, permanent secretary; Mario Quinones, annual secretary; and Manuel Martinez Baez, treasurer.

FOREIGN

Course in Otolaryngology—The Association of the Hospitals of Paris for Medical Instruction announces a week's course in otolaryngology to be given May 4-9, inclusive. Registrations for the course will be received up to April 15 by Dr Louis Leroux, 242 bis Boulevard Saint Germain, Paris. Among the subjects listed are laryngoscopy, ocular nystagmus, total laryngectomy, diagnosis and treatment of cancer of the larynx, surgical treatment of ozena, petrositis, ethmoiditis, surgery of the labyrinth and osteomyelitis invading the brain.

Society News—The German Society for Tropical Medicine will meet in Hamburg June 2-3. The official journal of the society changed its title January 1 to *Archiv für Schiffs- und Tropenhygiene*.—The fifteenth session of the "Medical Days" of Brussels will be held at the Free University of Brussels June 20-24, under the presidency of Dr Robert Danis. For information write Dr R. Beckers, secretary general, 141 rue Belliard, Brussels.—The fourth International Congress of Pediatrics which was scheduled for this spring in Rome, has been postponed until the latter part of September, according to the *Journal of Pediatrics*.

Congress of Jewish Physicians—The first World Congress of Jewish Physicians is to be held in Jerusalem at the Hebrew University and Tel Aviv, April 21-24. The program includes reports on the situation of Jewish physicians, reports on medical education, hygienic conditions of the Jewish population in Palestine and other countries with large Jewish population, Jewish institutions for preventive medicine and sanitary service, foundation of a world union of Jewish physicians, and scientific lectures on anthropology and eugenics. For information concerning reduced rates and special facilities apply to Amalgamated Bank of New York, 1111 Union Square, New York.

Government Services

Course in Aviation Medicine

At a dinner meeting of the U. S. Naval Reserve Medical and Dental Officers' Association in New York, recently the following medical reserve officers were awarded certificates for having successfully completed the course in aviation medicine in which they were enrolled: Lieut. Comdr. William J. Fordung, Manfred J. Gerstley, Max Gratz, Abraham Jablons, Walter R. Loewe and Oscar Wald, and Lieut. Lawrence A. Gerlach. The course was conducted by the medical office of the headquarters commandant, third naval district, Navy Department, and was the first of its kind to be held in the United States for naval reserve officers.

Physiologist Wanted for Air Corps Laboratory

The U. S. Public Health Service announces an open competitive examination for the position of associate research physiologist to fill a vacancy in the Air Corps, Materiel Division, Wright Field, Dayton, Ohio. The duties will be to establish equipment and operate a physiologic and biochemical research laboratory to investigate all phases of the effects of flying on the human organism. Competitors will not be required to report for examination at any place but will be rated on their education and experience. They must be citizens of the United States, must have graduated from a college or university of recognized standing with not less than twenty semester hours in physiology and must have had not less than three years' research experience in animal physiology and biochemistry. They must not have reached their forty-fifth birthday on the date of application and they must be in sound physical health. Applications must be filed with the U. S. Civil Service Commission, Washington, D. C., not later than March 30.

Precautions Against Anesthetic Explosions

The number of serious accidents due to anesthetic explosions in operating rooms has so far been small, but two main factors seem likely to increase them: (1) administration of ether and oxygen mixtures, which has become common, (2) the growing use of electrical apparatus close to the patient. A study of certain accidents in this country by the Ministry of Health has shown the need for precautionary measures, and after consultation with the factory department of the home office it has issued to local authorities and to health officers a memorandum, of which the following is a summary:

THE ANESTHETIC

A rich ether-oxygen mixture is more dangerous than a corresponding ether-air mixture, and a very small spark suffices for ignition. Nitrous oxide is not inflammable, but mixtures of ether vapor with air or oxygen are made more inflammable if nitrous oxide is added. Ethyl chloride yields a vapor that forms an explosive mixture with air and is dangerous in proximity to flames or apparatus likely to involve a spark and hot wires. The ordinary A. C. E. mixture may yield an explosive mixture with air and be dangerous under the conditions just mentioned. Explosions resulting from a mixture of ethylene and oxygen are very destructive.

The following methods of anesthesia are available when explosive risks may be anticipated: basal narcosis, local anesthesia, nitrous oxide, chloroform. But chloroform is not always advisable, and local anesthesia may be impracticable. Then the risk of ether may be minimized by limiting its administration to the induction of anesthesia. After an interval sufficient for elimination of the ether vapor, electrical apparatus may be used, anesthesia being maintained with chloroform or nitrous oxide and oxygen. Risk of ether explosions may be lessened by using a rigid closed circuit with carbon dioxide absorption. With a tightly fitting mask, no anesthetic should then escape into the air.

ANESTHETIC APPARATUS

In some types of apparatus it is possible for an explosive mixture containing ether to be delivered, although the valve or tap is set to admit chloroform or nitrous oxide only. This is due to evaporation combined with the slight suction effect of the gas flow and is more likely if the ether bottle is surrounded by a hot water jacket. The casual emptying of the ether bottle is not only no safeguard but a possible danger. The ether bottle should be altogether detached and not replaced until all traces of ether have been removed, or it should be fitted with an effective valve which closes the outlet when ether vapor is not required. It has been established by experiment that ether-oxygen mixtures can ignite along a tube such as that used in intratracheal administration, or in conjunction with a mask. If ignition occurs at the outlet, a flame may therefore reach the ether bottle, causing a burst with ejection of burning ether. Enclosed suction pumps should be so constructed that the exhaust delivery is outside the motor case. Otherwise in nose and throat operations the air-containing ether may be sucked in until concentration within the explosive limits is reached.

ELECTRICAL APPARATUS

It is unwise to use diathermic apparatus if ether must be administered as the cutting arc or spark can ignite ether air or ether-oxygen. A blanket or other screen between the patient's head and the point of application of the electrode is not a reliable safeguard. Further risks of ignition arise from

the spark gaps within the cabinet and from the possibility of the patient being at an electrical potential with consequent risk of sparking to the operator or other conducting bodies

In x-ray apparatus, careful construction of the electrical part and of the method of connection is essential for use in the presence of inflammable anesthetics. Sparking may occur from a defect in insulation, at switches, regulators, fan cooling motors or plug and socket connectors, the danger depending on the ventilation and proximity to the patient

Surgical lamps have to be small, which has led to a form of construction that is not robust and therefore tends to fail with use. Sparking may be caused by accidental short circuiting of exposed terminals or by failure of insulation or intermittent contact. Sparking is particularly dangerous in nose and throat operations under ether oxygen anesthesia. The danger of ignition is less with small low voltage dry cells than with other forms of supply, such as accumulators, transformers, motor generators and large dry cells. Grave risk of sparking is introduced by direct connection with public supply mains

In addition to the possibility of sparking the heat of an electrical cautery may ignite ether vapor. Ether-oxygen ignites by contact with hot metal at 300 C, which is below visible red heat

STATIC ELECTRICITY

Under ordinary conditions the atmospheric humidity in this country is sufficient to prevent dangerous static electrification but on very dry days or in rooms to which only dry warm air is admitted sparking is possible. Insulated apparatus such as rubber-tired patients' trolleys or portable anesthetic equipments can be electrified in various ways, for example, by drawing a dry blanket or towel across them. Discharge by sparking may ignite ether-oxygen mixtures. This danger can be eliminated by humidification of the air or by earthing by means of a light trailing chain from trolley metal work to the floor. Ventilation is an effective means of preventing anesthetic explosions

ANESTHESIA ACCIDENTS

The following accidents recently occurred in this country

1 During an operation for dilation of a cancerous growth of the esophagus, while the surgeon was withdrawing a small surgical lamp an explosion occurred in the patient's mouth and also at the anesthetic apparatus, which burst into flames. The oxygen stream through the ether bottle had been stopped and the latter had been set to deliver chloroform and oxygen. It was found that some ether might have been drawn from the open delivery side of the bottle to join the main current of oxygen and chloroform

2 While anesthetic equipment on a rubber-tired vehicle was being pushed alongside a similarly tired patient's trolley an explosion occurred, injuring both patient and anesthetist. The air supply was treated and delivered by a ventilating plant and consequently was of low humidity. It was found that the insulated trolleys could be readily electrified by sharp movements of blankets. This possibility is now obviated by trolley chains

3 A diathermy operation was in progress for carcinoma of the epiglottis. Intratracheal chloroform anesthesia was used but the anesthetist thought it desirable to change to ether. An explosion occurred when the diathermy electrode was in the mouth. Some of those present were injured by the flying glass, and the patient subsequently died

Inadequacy of Precautions Against Poison Gas

It seems to be past the wit of man to provide adequate protection against one of the latest developments of civilization—the bombing of cities with poison gas. In a press interview Sir Gowland Hopkins, the president of the Royal Society and our leading biochemist says: "If people are led to believe that gas masks alone will give protection they will be given a sense

of false security. It would at least be necessary to provide suits. The enormous cost would be prohibitive." He has in mind poisons such as mustard gas, which penetrate ordinary clothing and attack the skin. He adds: "The growing tendency in official quarters of this and other civilized countries to accept the use of aircraft for unrestricted bombing and gas attack on civil populations is dangerous. The only defense is to abolish this form of warfare. The danger is that the public may be led to believe that science can give them complete protection." With the continued improvement in incendiary bombs, the fire peril grows greater. Some of the latest of these missiles, though more effective than ever, now weigh only about a pound. One small plane can carry hundreds. They burn with the intensity of magnesium and explode if water touches them. It is claimed that whole cities could be dotted with fires in a few minutes. It is impossible to look at the blaze from these bombs with the naked eye

Tests with babies are being made by designers of the antigas containers which the government will distribute to parents in the event of another war. It was necessary to discover how an infant would react to varying air pressures. This was done by placing a baby in the container and observing its breathing. Poison gas, of course, was not used in the experiment. Experts have not yet been able to discover how to save a baby from suffocation if the parents working the pump that supplies air to the container are killed or disabled

Murder by Plague Bacillus

In a previous letter to *THE JOURNAL* the case was reported in which a rich landowner of Pakur, in the province of Bihar, India, received a prick from an unknown man at a railway station in November 1933 and became ill and died. It was subsequently found that his stepbrother had tried to obtain a culture of the plague bacillus at the Haffkine Institute, Bombay, and that when he failed an Indian physician obtained one by representing that he wanted it for research. The stepbrother also appeared to have made a previous attempt of the kind on the life of the deceased. Both men were charged with conspiracy to murder, and they were convicted and sentenced to death. The case has just come before the high court of appeal which commuted the sentence to transportation for life. The appeal bench observed that the case was unique in the annals of crime. The court commuted the sentence in view of the circumstantial nature of the evidence but held that the only reasonable inference was that the two men conspired to murder the deceased, for which purpose they provided some person or persons unknown with the plague obtained in Bombay, who at their instigation succeeded in infecting the victim. Part of the reason for commuting the sentence was that this course might lead to the discovery of the actual perpetrator of the crime

Precautions Against Carbon Bisulfide Poisoning

The factory department of the government has issued a memorandum on precautions against poisoning, fire and explosions that may occur in the use of carbon bisulfide in artificial silk, india rubber and other manufactures. Poisoning arises from the inhalation of small quantities of the vapor over periods of weeks or months. The first symptoms are nausea, indigestion, giddiness and hysterical disturbances. Other symptoms are an appearance of anxiety with sweating of the hands and forehead. In the next stage there is impairment of memory, mental dulness and depression. Speech may be affected with contraction of the visual fields and diminished power of accommodation. Toxic neuritis may manifest itself by muscular weakness, first in the muscles of the face and flexors of the forearm. Difficulty in walking leads to paralysis. Late symptoms are tremor, paresthesia, loss of sensibility and optic neuritis

Carbon bisulfide poisoning in factory or workshop is compulsorily notifiable. Since 1924, eighteen cases have been notified in this country. Among the precautions laid down for prevention is the medical examination of workers at intervals not exceeding one month. The storage and pipe conveyance of carbon bisulfide must be satisfactory and explosions must be guarded against.

Meningitic Forms of Icterohemorrhagic Spirochetosis

Mollaret, of the Institut Pasteur, read three papers before the Societe medicale des Hopitaux de Paris on meningitic infection by *Spirochaeta icterohaemorrhagica*.

A fisherman in Seine came to the hospital with meningitic symptoms and in a few days had serious cardiorenal complications. The first lumbar puncture showed a normal spinal fluid, but the second made on the sixth day, showed a meningitic reaction. The patient died suddenly on the seventh day from heart failure. Postmortem examination proved the spirochetic nature of the disease. The second patient was a garage man in a garage infested by rats. The spirochetic infection was not less authentic, but in this case the lumbar puncture revealed directly the meningitic condition. This was the only evidence of a spirochetic complication, in the lack of any clinical symptom. The disease was principally a generalized icterus with azotemia and albuminuria.

In their second paper, Mollaret and his co-worker Berthe Erber discussed the diagnosis of meningitic spirochetosis. The presence of the spirochete cannot be found in the spinal fluid. The spirochete is difficult to find in the urine, and as for inoculation in the rabbit, one can always suspect some attenuation of its virulence in the course of research. Best is serodiagnosis. Among the different techniques the authors prefer the Martin and Pettit method, which involves agglutination of a virulent culture of spirochetes in increasing quantities of studied serum dilutions. A difficult question is the so called zone action of agglutination. Agglutination never appears before the 1:10 dilution and is not actually seen in most cases before higher dilutions, 1:100, or even 1:500 or 1:1,000. As a matter of fact, the positive tests always include the absence of agglutination in the first low dilutions. On the other hand, the meningitis being just an atypical form of spirochetosis, one may question the lack of causality between positive tests of spirochetosis and actual meningitic symptoms. The positive tests could include evidence of some former infection, not necessarily connected with the present infection. The authors answer the objection, pointing out that other spirochetes or other stocks do not show this absence of agglutination with low dilutions which is characteristic of *Spirochaeta icterohaemorrhagica*. The morphology of agglutination allows some differentiations between the latter and the former.

In the third paper Mollaret turned his attention to the physiopathologic sides of meningitic spirochetosis. In such cases, instead of a simple and ordinary propagation of the spirochetal infection to the meninges, from outside to inside the whole disease seems to develop as in a closed vessel in the interior of the meninges. Apropos of such cases contamination by the ethmoid was suggested in infested rivers, or by conjunctivitis and the problem was that of permeability or nonpermeability of the agent from inside the meningitic sac to the outside. From study of the meningitic permeability to fuchsin comparison between blood and spinal fluid agglutinins, and from some experiments on monkeys the authors conclude that the reactions in the two diseases are identical. The pure spirochetic meningitis is consequently of the same value as any other visceral determination no matter what kind of spiro-

chetes are involved, as the cause of the ailment. As they themselves admit, these views are hypothetical and many questions remain unsolved.

American Memorial Hospital in Reims Enlarged

In 1925 Ambassador Merrick laid the first stone of the American Memorial Hospital in Reims, one of the most sorely tried of the French cities of the East. The funds, all of American origin, were given by many benefactors and organizations. The chairman of the corporation was, and still is, Miss Edith Bangs, the medical director is Dr. Marie Louise Lefort. The building, located in the suburbs of Reims, is a large one, with a pretty garden relieving the plainness of the exterior, and it dominates the surroundings, which are rather severe. The medical facilities are adequate to supply medical and surgical care to 112 children from birth to 14 years of age. The founders were apparently a bit too optimistic. They combined with the hospital a nurse school and to make room for the student nurses were obliged to lower the number of occupied beds. When some repairs were needed on the walls and roofs last year, one floor was added and the initial number of 112 beds installed. Happily, some funds remained free from the first gifts, which were good dollars and had fructified steadily over many years. They were sufficient to complete the building and the American Memorial Hospital of Reims is now at its full extent. The names of the benefactors, mostly American, are piously engraved on the pleasant walls of the hospital.

Traumatic Epilepsy in Ex-Service Men

The follow-up examination of brain injuries over a period of twenty years became possible to Dr. Baumeier, who in his official capacity has examined war veterans of the Dresden district presenting brain injuries. Under brain injury cases the Dresden welfare bureau for disabled veterans classifies men who have suffered direct brain injury even when no noticeable results of the injury were apparent, men whose injuries were followed by neurologic and psychic disturbances and veterans presenting traumatic epilepsy as a result of such injury. Men whose injuries were confined to the cranial bones or the dura were not so classified. The following were the principal symptoms presented by the men with brain injuries: uniform headaches markedly dependent on the weather, attacks of vertigo, slight irritability, increased susceptibility to mental fatigue and troubled sleep. Baumeier made follow-up examinations of 340 such cases in recent years. The most important fact noted from these examinations was the progressive deterioration manifest in many cases. This took a quite different course in various cases. Mental deterioration was more frequent than local phenomena, aphasia or dementia paralytica. Of the men with brain injuries undergoing follow-up examinations, 24 per cent presented traumatic epilepsy of the grand mal type, in a few cases jacksonian type convulsions without loss of consciousness were observed. Cases of absolute unconsciousness were infrequent. A prolonged state of stupor is as rare in traumatic epilepsy as are dementias, which may be observed in true epilepsy. The interval between brain trauma and the appearance of traumatic epilepsy varies greatly from more than eighteen years to only a few weeks. Heretofore not enough attention has been paid to mental deterioration without traumatic epilepsy. All stages are possible in these cases, from the mildest anemic disturbances to the most severe types of dementia. The men complain but little and show themselves negligent of their own interests. It is their relatives who first urge pension increases, medical treatment and so on. The condition of traumatic dementia although multiform almost always shows a diminution

tion of the power of judgment and increasing irritability the spheres of interest become greatly restricted. A further type exists in which the frontal brain has been injured this is characterized by a great weakness of impulse, inordinate optimism and a permanent dazed condition without loss of consciousness. Fatal cases of purulent meningitis were also registered. On the other hand, some severe brain injuries had no consequences. When the injury was to the cranial bones, the patients had fewer headaches. Administration of a huge amount of narcotics was necessary often in large doses. Traumatic epilepsy may be treated like true epilepsy but with less success.

Herpes Simplex

The etiology of herpes simplex has yet to be explained. Prof. Otto Naegeli, the Bern dermatologist recently lectured on the subject before the Munich Medical Association. Herpes should be classed among infectious diseases even though it does not possess various characteristic indications. Naegeli has successfully accomplished transmissions of herpes, but proofs of person to person transmission are as yet lacking. Herpes would seem to be a defense mechanism of the human organism. It has a definite location and appears again and again in the same manner in some particular favorite place as on the mouth and nose. The virus thus seems to be restricted to a certain locality. It may also have its site in the region of the anus or on the skin of the face. Incontestable infection by contact has not yet been observed. Whether or not a febris herpetica actually exists is still debatable. The assertion that febrile diseases may take a course favorable to the simultaneous appearance of herpes is based on experience in practice. Familial appearances of herpes have been repeatedly observed. Herpes may attack in many different manners. Children up to 5 years of age are seldom if ever attacked. Herpes chiefly occurs during the period from the middle of the second decade to the middle of the third. It is frequently encountered with epidemic meningitis. According to experience, whenever herpes makes its appearance in severe diphtheria the latter disease will run a much milder course than if herpes is absent. The same holds true for metasyphilis with the exception of tabs. Likewise in malaria therapy, Naegeli has learned by experience that better therapeutic results (speedier destruction of the nonmotile spirilla symptomatic improvement) may be observed coincident with eruptions of herpes.

Instruction in Technical Hygiene

According to a recent ministerial order instruction in technical hygiene (medical care in accident and occupational disease cases) is to be introduced as a subject of study. Moreover, the ideal sought is that no special lectures need be given but rather that this field may be completely divided up, each professor treating in conjunction with his regular lectures such aspects of the subject as pertain to his own field.

Prof. Ludwig Aschoff 70 Years Old

The eminent professor of pathologic anatomy of the University of Freiburg in Breisgau celebrated his seventieth birthday January 10. Aschoff has always recognized those fundamental principles of Virchow which time and increased knowledge have done much to develop. Aschoff's work embraces nearly all fields of general pathology and pathologic anatomy. He will probably be chiefly remembered for his contributions on thrombosis and on nephritis and for his studies on the origin of inflammations. His entrance into a discussion always adds something of value even when he evokes opposition. In the preface to his textbook of pathologic anatomy, Aschoff expresses himself as follows: 'Let there be but one opinion and you have an end of research and knowledge.' Already in his first major endeavors in the field of pathologic morphology Aschoff strove for a better comprehension of the pathologic processes and of the causes and nature of symptoms. Among his many

other achievements was his explanation, in collaboration with Tawara, of the bundle of His and his work on pulmonary tuberculosis, on the functional organization of the stomach, and on the reticulo-endothelial system. He has made it possible to formulate a general theory of disease. He constantly has explored the connecting links between his own and other fields and in this way has gained a knowledge of new methods and trends that might be applicable to his own narrow specialty. One has only to recall, for example his work with cholesterol. Hand in hand with his manifest ability as a scientist go a lively technique of presentation and an extraordinary mastery of language, gifts all of which combine to place the name of Aschoff among the most illustrious in his field.

Congress of Psychiatry and Neurology

The thirty-ninth session of the Congress of Alienists and Neurologists of France and French speaking countries was held at Brussels. Among the subjects discussed were (1) hysteria and the psychomotor functions and (2) hysteria and the thalamencephalic functions. Mr. Paul Vervaeck discussed juvenile delinquency and criminality pointing out that among the etiologic factors in juvenile delinquency the family milieu is important. Research undertaken in America and confirmed in Belgium shows that delinquency tends to have as its foci certain quarters and street corners that are nests of criminality. The influence of the youthful gang or that of individual pals cannot be underestimated also the role of the cinema remains one of the most debatable questions. To cope with juvenile delinquency an extensive array of well equipped institutions and efficient procedures is requisite: liberty under surveillance, semi-liberty at home, placement away from the family, private detention homes, public detention homes, institutions for acute psychopaths and the mentally debilitated. In each of these procedures the cooperation of the psychiatrist is necessary. He is able to imbue efforts at readjustment with a sense of individual orientation. Such efforts presuppose an efficient personnel and a meticulous classification of the children. The Belgian rehabilitation homes furnish a fine example of what may be attempted in this field. Preventive measures in juvenile delinquency must not rely too much on purely medical disciplines or on eugenics. The best prophylaxis based always on a good mental hygiene, should consist of such measures as enlightenment of ignorant parents, better orientation of school children showing criminal predispositions the best possible program of work and recreation for adolescents. Children of abandoned morals should, on the authority of a magistrate of the juvenile court or others having tutelary jurisdiction, be committed to a private institution or perhaps with better results to those public or semipublic organizations the ramifications of which are to be found everywhere. Each of these steps in the prevention and treatment of delinquency opens up a wide field of activity for the psychiatrist.

Cancer in Slaughtered Animals

After an interchange of correspondence between Mr. Hautekeer, vice president of the Federation of Animal Protection Societies of Belgium the minister of agriculture and the minister of the interior and of hygiene, it was decided that an investigation of cancer in slaughtered animals be launched at the Royal Medical Academy of Belgium, first by gathering information from the directors of the country's principal abattoirs and secondly by requesting that these directors make a collection of such tumors as might be encountered in the course of their examinations and send them to the department of pathologic anatomy of the School of Veterinary Medicine. In

a year the slaughterhouse officials sent in fourteen shipments containing twenty-four selected specimens (four horses, eight head of cattle, one pig). Of these specimens only six were tumors, the remainder had to do with tuberculosis. Mr. Antoine, who reported on this question, has likewise attempted to collect tumors found in draft or farm animals. He was able to obtain only six specimens (four from horses, two bovine). For his part, Dr. Willems, director of the Laboratory of Veterinary Inspection, could collect data on a few rare cases of cancer in slaughtered animals. According to statistics compiled in several foreign countries, cancer seems to be rare in bovine creatures but of course the fact remains that as yet these statistics are of but approximative value. In Belgium, examination after slaughter is required by law. The conditions under which total condemnation of a carcass is justified, however, possess no indication relative to cancer. General melanosis alone calls for total condemnation. In cases of partial condemnation, it is merely a question of condemning affected parts rendered unfit to be eaten by reason of injuries, abscesses, cysts, calculi, parasites or chronic deterioration (as of a visceral organ). Nor in dealing with these cases does the law make the slightest reference to cancer. Mr. Antoine requested that "tumors be made mention of in those sections of the law which govern partial condemnation, and furthermore that the sections governing total condemnation should no longer refer to general melanosis but rather to generalized tumors or tumorous changes in certain organs. The prevalent opinion resulting from the discussion was that, considering the present state of our knowledge of cancer, it is important that the statute be amended to provide for a closer examination of meats destined for consumption and to prohibit sale in case of tumorous conditions, which certainly must be more frequent than existing statistics would lead one to believe.

Medicine Pertaining to Sport

The Società di Medicina Sportiva met recently at Bologna under the chairmanship of Prof. Ugo Cassinis. Prof. Giovanni Pini of Bologna spoke on sport medicine in Italy. Sport medicine has developed greatly in Italy during the last few years. The number of practitioners in this branch of medicine is 2,000. Italian universities have made it their duty to provide sport physicians trained by competent teachers. Societies pertaining to sport medicine are obliged to employ the services of sport physicians. As a basis for the evaluation of the physical constitution of athletes in collecting international data, Viola's method of anthropometric-morphologic and physiologic measurements has been universally accepted since its verification at the congress held in Chamonix in 1934. The establishment of a university center for research in sport medicine has been suggested. Pini believes that better results would be obtained from the establishment of various regional centers located in state capitals.

Professor Cassinis studied accidents caused by athletics in the first year that the insurance branch, Cassa di previdenza, was in operation. Of 97,489 insured athletes there were 2,177 cases of traumatic injuries, the greater number of which occurred during football. According to the number of athletes who participate in athletics in relation to the number of accidents that occurred, the following percentages were obtained: accidents caused by English rugby (football), 9.90 per cent; boxing, 4.18 per cent; 'heavy weight' athletics, 4.14 per cent; and football, 3.70 per cent. Mountain climbing gave a low percentage, 0.42 of accidents during the year, but the number of deaths was high (eighteen). The location of traumatic lesions varies with the sports and is typical for each group of sports, especially for football, boxing and cycling. For all sports taken

together, contusions, distortions and fractures predominated. Among 2,177 accidents that occurred, permanent disability, either partial or total, was produced in 481 cases, or 22.04 per cent. The high percentage of accidents is due to the manner of playing the games and depends on the training of the players and on the application of the fundamentals during actual playing. In the groups of athletes of universities, more than 125,000 athletes were insured. Traumatic lesions occurred in only ninety-four cases of the group, resulting in permanent disability in three cases.

Professor Tranquilli made a statistical study of trauma caused by sport during the last five years and reviewed the 800 cases reported.

Professor Donaggio spoke on the Donaggio reaction and of its value as a test of fatigue. He stated that the obstruction phenomenon observed in the urine following physical exertion is a manifestation of a general reaction of the organism to intense muscular work and that it is more sensitive than the modifications of both the velocity of speed of the erythrocytes and of Arneith's formula.

Castellani in Military Service in Africa

Dr. Aldo Castellani, director of the clinic of tropical diseases at the University of Rome, has been appointed head of all the medical services, both military and civil, in Italian East Africa. Steps have been taken under his direction to prevent the appearance and spread of infectious diseases. All centers of military activities are provided with abundant supplies of water made potable by purification and filtration. Soldiers are given vitamins to complement their rations. They are provided with day clothing and wool covers to protect them against the changes of temperatures. Bacteriologic laboratories, centers for isolation of patients, have been established. Care is given to the early detection of infectious diseases, disinfection, disinfection of places and betterment of the health conditions of camps and prisons. The network of sanitary centers includes military hospitals in connection with hospitals in Asmara and Massowah and with hospital ships, one of which is stationed in the port of Eritrea. Hospitals for convalescents, ambulant departments with experts for roentgen and dental work, auto mobile ambulances and railroad cars provided with equipment for sanitary work are all units of the sanitation of the colony which has been organized during the present military activities.

Psittacosis in Vienna

At the last session of the Vienna Society of Physicians, a woman patient from the clinic of Professor Eppinger was presented whose illness had been at first diagnosed as pneumonia. At the time of her admittance, despite quite trifling objective symptoms, the patient appeared severely ill. The localized nature of the pneumonic development aroused a suspicion of psittacosis, all the more as the patient had kept in her home two zebra-parakeets, one of which had sickened and died. Twelve days after the onset of the illness, samples of sputum were sent to the federal institution for campaigning against diseases of animals, where a diagnosis of psittacosis was made. It is noteworthy that in this case for the first time the director, Professor Gerlach, succeeded in culturing the typical causative agent of psittacosis in the blood serum as well as in the sputum. The patient, although nearly recovered, remained in quarantine. In the meantime the second bird had died and it was also found to have been infected. Thereupon the bird store which had sold the pets was investigated and an examination of the living parakeets in stock revealed a whole series of disease carriers. The store's entire stock of 146 birds, including zebra parakeets

canaries, wood birds and two birds of paradise was ordered destroyed. Examination of the 146 bird cadavers showed infection to be present in a large majority. Professor Eppinger who observed an epidemic of the disease in the Rhineland some time ago stated that the wandering of the pneumonic focus such as had aroused suspicion in this Viennese case is a characteristic symptom. The discrepancy between the severity of the symptoms and the meagerness of the objective signs is also typical. Professor Gerlach, who like Eppinger, also was in his time a member of the commission for the campaign against psittacosis emphasized that not only parrots but also canaries can be infected with the disease and in turn become carriers. When, however canaries have had no contact with diseased birds that is to say when they come from domestic breeding places, they are (and the same applies to home-bred as distinguished from imported parakeets) not dangerous. Caution should, however be exercised with regard to such birds. Several times in the past year breeders of zebra-parakeets were stricken with pneumonia—one case ending fatally—without psittacosis being proved. Frequently small epidemics break out in seaports where sailors occasionally bring in infected parrots. Under such circumstances the disease is neither quickly recognized nor checked. Therapeutic measures in cases of psittacosis in man are at present only symptomatic. The mortality in epidemics observed fluctuated between 5 and 30 per cent.

The Campaign Against Hereditary Disease

In the course of a series of papers on "The Science of Heredity and Race" Prof Julius Bauer spoke anew on "The Significance of Heredity in Man." This scholar an acknowledged authority in the field has reiterated his opinion that the theory of race as promulgated by the present rulers of Germany is based on false premises and leads to false conclusions. Dr Bauer's views have made him hated by Nazi officials. The German delegations were forbidden to participate in the International Congress of Internists in Switzerland in 1935 unless Dr Bauer was excluded. The Swiss convention was forced to yield to this pressure (or extortion) and to request that Dr Bauer withhold his paper. In his latest lecture this scholar stresses the great significance of the proportions assumed in the last few years by the movement for a humanitarian application of man's knowledge of genetics. Particularly in Germany, legislation has been attempted which seeks to exercise preventive control of the aftergrowth of tainted heredity and which therefore authorizes the sterilization of insane persons and others classed as burdensome to the state. Sterilization of these persons is, however as Bauer emphasizes no adequate way to protect the humanity of the future from those who come into the world with a congenital disease. The only result of such sterilization is that a negligibly small number of persons is prevented from propagating. But at least 75 per cent of all living human beings possess pathologic inherited predispositions consequently since only some 25 per cent are free from such predispositions, the German legislation can never accomplish its professed purpose the improvement of the race. It would be necessary to carry out this sterilization through from thirty to fifty generations. Moreover it is a matter of common knowledge that many persons unwittingly possessing pathologic hereditary predispositions have made valuable and even great contributions to the cultural development of their race (among others Beethoven Spinoza Mendelssohn Nietzsche Mohammed Napoleon). Important results have been yielded by studies of the vital processes of uniovular twins. The physical development as well as the mental (criminal type) of such twins takes place simultaneously in a perfectly homogeneous manner. Their fingerprints too are almost identical and the same holds true for their endowments and aptitudes.

Marriages

ADOLPHE P. DELCOURT Hammond Ia to Miss Marion Weston of St Francisville in New Orleans Dec 12 1935

CHARLES WALTON PURCELL University Va to Miss Clco Virginia Ashby in Raleigh N C January 18

ROBERT P. JEANES Casley S C to Miss Martle Helen Nelson at Spring Grove, Minn Nov 23 1935

Deaths

Southgate Leigh @ Norfolk Va University of Virginia Department of Medicine Charlottesville 1888 College of Physicians and Surgeons, Medical Department of Columbia College New York, 1889, member of the House of Delegates of the American Medical Association 1916 1933 past president of the Tri-State Medical Association of the Carolinas and Virginia Seaboard Medical Association Atlantic Coast Line Railway Surgeons Norfolk and Western Railway Surgeons Association Chesapeake and Ohio Railway Surgeons Association Southern States Association of Railway Surgeons Norfolk County Medical Society and the Medical Society of Virginia a founder governor and fellow of the American College of Surgeons member of the Southern Surgical Association, founder visiting surgeon and gynecologist Sarah Leigh Hospital consulting surgeon to the Norfolk Memorial Hospital in 1929 awarded the Distinguished Service Medal for the best civic work aged 69 died March 5 of cerebral hemorrhage

Charles Warren Hooper, New York Johns Hopkins University School of Medicine Baltimore, 1914 an Associate Fellow of the American Medical Association member of the Associated Anesthetists of the United States and Canada at one time fellow and assistant professor of research medicine Hooper Foundation instructor and assistant professor of research medicine University of California Medical School and the Hooper Foundation San Francisco for three years pathologic physiologist at the Hygienic Laboratory U S Public Health Service Washington D C formerly passed assistant surgeon in the reserve corps U S Public Health Service, director of research medicine for the H. A. Metz Laboratories and the Winthrop Chemical Company Rensselaer N Y aged 45 died January 27 in St Peter's Hospital Albany, of pneumonia

Henry Patterson Bagley @ Galesburg Ill College of Physicians and Surgeons of Chicago School of Medicine of the University of Illinois 1905 at various times associate and instructor in laryngology and otology Rush Medical College Chicago and assistant professor of ear nose and throat diseases at Loyola University School of Medicine Chicago served during the World War formerly on the staffs of the Chicago Eye Ear Nose and Throat Hospital St Mary's of Nazareth Hospital and the Illinois Charitable Eye and Ear Infirmary, Chicago aged 59 on the staff of the Galesburg Cottage Hospital where he died February 8 of pneumonia

William Burton De Garmo @ Coral Gables Fla, University of the City of New York Medical Department 1875 member of the Medical Society of Virginia professor of special and clinical surgery New York Post Graduate Medical School and Hospital 1888 1918 and since 1918 consulting surgeon, fellow of the American College of Surgeons, captain in the medical reserve corps in 1917 author of "Abdominal Hernia—Its Diagnosis and Treatment" 1907 aged 86 died January 3, as the result of a hip fracture received in a fall

William Henry Wenning, Cincinnati Miami Medical College Cincinnati 1871 at one time clinical professor of gynecology at his alma mater, professor of obstetrics at the Woman's Medical College and the Cincinnati Medical College for many

cars president and member of the staff of St Mary's Hospital at one time president and secretary of the Cincinnati Academy of Medicine, aged 85, died, Dec 25, 1935, of angina pectoris and coronary occlusion

Lyne Arthur Hoag, Barrington, R I, University of Michigan Medical School, Ann Arbor, 1918, associate professor of pediatrics, Cornell University Medical College, New York at one time instructor in pediatrics and infectious diseases at his alma mater, assistant professor of anatomy Vanderbilt University Medical Department Nashville Tenn and assistant in pediatrics, Harvard University Medical School, Boston aged 43 died, February 16

Frederick McDonell Harkin ♂ Marquette Mich McGill University Faculty of Medicine, Montreal, Que Canada 1885 fellow of the American College of Surgeons past president of the Upper Peninsula Medical Society health officer of Marquette attending surgeon to St Mary's and St Luke's hospitals, aged 72, died, January 23

Frederick August Baumgart ♂ Danville Ill College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1904, past president of the Vermilion County Medical Society on the staffs of the Lakeview Hospital and St Elizabeth Hospital, aged 61, died January 15, of angina pectoris

Harvey Bradley Gratiot ♂ Dubuque, Iowa Jefferson Medical College of Philadelphia, 1896, past president of the Dubuque County Medical Society, fellow of the American College of Surgeons served during the World War on the staffs of the Finley and Mercy hospitals, aged 61 died, January 13, of pneumonia

Gilbert B Pfoutz, Salt Lake City University of Pennsylvania Department of Medicine, Philadelphia, 1888, member of the Utah State Medical Association, fellow of the American College of Surgeons, member of the consulting staff of St Mark's Hospital aged 71, died, January 2, of chronic nephritis

Howard Fruin Hubbard ♂ Rome, N Y University of the City of New York Medical Department 1887 county coroner for many years president of the board of managers of the Oneida County Hospital, aged 67, on the staff of the Rome Hospital, where he died, January 1 of coronary thrombosis

Edward A Travis, Como Tenn, University of Louisville (Ky) Medical Department, 1881, past president of the Henry County Medical Society formerly member of the state legislature and county board of education, aged 75, died, Dec 28 1935 in a hospital at Paris, of bronchopneumonia

Thomas Charles Phillips, Milwaukee University of Michigan Department of Medicine and Surgery, Ann Arbor 1887 formerly professor of ophthalmology and otology and dean Wisconsin College of Physicians and Surgeons, aged 76, died, January 4, of carcinoma of the prostate

Daniel Oscar Willis, Leesville La Memphis (Tenn) Hospital Medical College 1904, member of the Louisiana State Medical Society, served during the World War, aged 60, died Dec 23, 1935 in a hospital at LeCompte, of injuries received in an automobile accident

Maurice Albert Stark, Newington, Conn Dartmouth Medical School Hanover, N H 1897, member of the New Hampshire Medical Society, served during the World War, on the staff of the Veterans Administration Facility, aged 61, died Dec 29, 1935

Wilson Boyd Catheart, Pittsburgh Western Pennsylvania Medical College Pittsburgh, 1888 member of the Medical Society of the State of Pennsylvania, aged 70, died, January 10 in the Hillview Farms Sanitarium, Washington, Pa, of lobar pneumonia

Tully Joseph Liddell ♂ Surgeon, U S Public Health Service Chicago Tulane University of Louisiana Medical Department New Orleans 1912, aged 49 executive officer of the U S Marine Hospital, where he died, Dec 1935, of coronary thrombosis

William Josephus Robinson ♂ New York University of the City of New York Medical Department 1893 author of numerous books on sex and urologic subjects, aged 66 died January 6, of essential hypertension and coronary artery thrombosis

Bert William Babcock, Grand Rapids, Mich St Louis University School of Medicine, 1903 member of the Michigan State Medical Society on the staff of the Michigan Soldiers Home aged 56 died suddenly January 8, of aortic insufficiency

John Pomfret Long, Sheffield Ala, University of Virginia Department of Medicine, Charlottesville 1907 member of the Medical Association of the State of Alabama, served during the World War aged 59, was found dead, January 4

William Russell Callen, Birmingham, Ala Tulane University of Louisiana School of Medicine New Orleans, 1903, member of the Medical Association of the State of Alabama, aged 58, died, January 29, of ruptured gastric ulcer

Charles E Colwell ♂ Aurora, Ill, Hahnemann Medical College and Hospital, Chicago, 1885, past president of the West Aurora School Board, on the staff of the Copley Hospital, aged 71, died, January 10, of angina pectoris

Edward Shafer Wendt, Toledo, Ohio, Miami Medical College, Cincinnati, 1902, served during the World War, on the staff of St Vincent's Hospital aged 59, died, Dec 31, 1935 of cardiorenal disease and rectal abscess

N A Jenkins, Columbia, S C, Leonard Medical School Raleigh, 1908, superintendent of the Waverly Fraternal Hospital aged 55, died Dec 22, 1935, in the Peter Bent Brigham Hospital, Boston, of myeloid leukemia

Arthur R Mattingly, New Orleans, Tulane University of Louisiana Medical Department, New Orleans, 1887 at one time member of the state board of health, aged 71, died, Dec 22, 1935 of chronic myocarditis

Frank Petty Hixon, Pensacola, Fla, Vanderbilt University School of Medicine, Nashville Tenn, 1898, served during the World War, aged 61, died, January 4, of chronic myocarditis and cardiac decompensation

Lewis B Hoagland, Oxford, N J, University of Pennsylvania Department of Medicine, Philadelphia, 1880, member of the Medical Society of New Jersey, aged 77, died, January 9, of chronic myocarditis

William F Stewart, New Martinsville, W Va, Jefferson Medical College of Philadelphia, 1881, formerly a druggist, aged 76, died Dec 27, 1935, of mitral stenosis and chronic pulmonary tuberculosis

Louis Rominger, Ann Arbor, Mich, Louisville (Ky) Medical College, 1899, member of the Michigan State Medical Society, aged 76, died, January 2, in the Harper Hospital, Detroit, of carcinoma

Kiyoshi Matsumura ♂ San Francisco, University of California Medical School, San Francisco, 1928, aged 47, died January 5, of tuberculosis of the lumbar spine, arthritis and multiple infections

Sumner J Ricker ♂ Aurora, Ill, Hahnemann Medical College and Hospital, Chicago, 1871, College of Physicians and Surgeons of Chicago, 1891, aged 88, died suddenly, January 4, of heart disease

Malachi R French, Evansville, Ind, Pulte Medical College Cincinnati, 1880 on the staff of the French Hospital, aged 77, died, January 7, in St Mary's Hospital, of coronary thrombosis

Stephen Edward Ulmer, Cleveland, Jefferson Medical College of Philadelphia, 1896, aged 67, died, Dec 30, 1935, in the Grace Hospital, of chronic nephritis, arteriosclerosis and myocarditis

George W Richardson, Westpoint, Va, Medical College of Virginia, Richmond 1880, aged 76 died, Dec 28 1935, in the Johnston Willis Hospital, Richmond, of cerebral hemorrhage

Hubbard McKee Hoyt, Pacific Grove Calif, Chicago Homeopathic Medical College, 1886, aged 77, died, January 3 of paralysis agitans, Parkinson's disease and bronchopneumonia

Astus S Magee, Pensacola, Fla, Louisville (Ky) National Medical College, Medical Department State University, 1910, aged 57 died, January 8, of malignant neoplasm of the bones

John Oliver Nichols, Ftowah, Tenn Tennessee Medical College, Knoxville 1894 member of the Tennessee State Medical Association, aged 64, died, Dec 31, 1935, of pneumonia

Myron G Spawn, Beloit, Wis, Hahnemann Medical College and Hospital Chicago, 1890, formerly health officer of Beloit aged 73, died, Dec 23, 1935, of Parkinson's disease

George Patrick Morris, Boston Harvard University Medical School, Boston, 1891 member of the Massachusetts Medical Society, aged 75, died, January 4, of cerebral thrombosis

Peter Stewart ♂ Royal Oak Mich, University of Michigan Department of Medicine and Surgery, Ann Arbor, 1891, aged 66 died January 2, of coronary sclerosis and thrombosis

Isabel Haslup Lamb, Washington, D C, Howard University College of Medicine, Washington, 1897, aged 71, died, January 18, of coronary occlusion and chronic myocarditis

Joseph W Eargle, Chapin, S C, Medical College of the State of South Carolina, Charleston, 1874, aged 88, died, January 4, in the Baptist Hospital, Columbia, of pneumonia

Haynes Brinson, Kissimmee, Fla., Atlanta (Ga.) College of Physicians and Surgeons 1912, member of the Florida Medical Association, aged 52, died, January 7, of myocarditis

Cecil S Hudson, Rosbank, N Y Baltimore Medical College, 1905, since 1921 acting assistant surgeon, U S Public Health Service, aged 57, died, Dec 27 1935

Frank F Finch, Cleveland Heights, Ohio, Cleveland University of Medicine and Surgery, 1895 aged 63, died, Dec 29 1935 of chronic nephritis and myocarditis

Vincent Joseph Noone, Indianapolis, Indiana University School of Medicine Indianapolis, 1931 aged 29 died, January 4, in St Vincent's Hospital, of pneumonia

William James Burden, Rochester, N Y Trinity Medical College, Toronto Ont Canada, 1895 aged 67 died, January 10, of myocarditis and diabetes mellitus

Henry Wendell Colborne, Wingham Ont Canada, Western University Faculty of Medicine London, 1922, aged 42, died suddenly, January 28, in Toronto

Thomas Moran, Biddeford, Maine Vanderbilt University School of Medicine, Nashville, Tenn, 1903, aged 76, died, January 3, of cerebral hemorrhage

Hiram Knox Butler, Summit Miss, New Orleans School of Medicine, 1869 Confederate veteran aged 88 died, January 3, of hypertension and nephritis

Landon O Rodes, Sikeston, Mo, Missouri Medical College, St Louis, 1890, aged 70, died Dec 24 1935, of arteriosclerosis and coronary thrombosis

Joseph Cannon Ellis, Philadelphia Jefferson Medical College of Philadelphia, 1888, also a minister aged 74 died, January 4, of bronchopneumonia

James Jackson Stewart, Mount Holly N C North Carolina Medical College, Davidson, 1904, aged 59 died, January 1, of a self-inflicted bullet wound

William Kent Ruble @ Seattle Tulane University of Louisiana Medical Department, New Orleans, 1924, aged 39, died, January 1, of pneumonia

Joseph Bostock McHenry, Minerva, Ohio Medical College of Ohio, Cincinnati, 1907, served during the World War, aged 58, died, Dec 24, 1935

William Gabriel Lewis, Eufaula Ala Atlanta Medical College, 1884 aged 75, died, Dec 26, 1935, as the result of an injury received in a fall

Ernest Leslie Ward, Elkland Pa Medico-Chirurgical College of Philadelphia, 1902, aged 59 died suddenly January 1, of coronary thrombosis

George Baxter Poole, Nashville, Tenn, University of Nashville Medical Department, 1910, aged 50 died, January 3 of cardiac thrombosis

Frank Temple Lamb, Berkeley Calif, California Medical College, San Francisco, 1896, aged 77 died Dec 26 1935, of bronchopneumonia

Daniel Robert Hughes, Lewistown, Pa, Temple University School of Medicine, Philadelphia, 1927, aged 35, died, January 5, of heart disease

Carlton A Bates, Hillsdale, Mich (licensed in Michigan in 1900), aged 63, died, January 5, of chronic endocarditis and cerebral embolism

Alonzo A Kester, Fort Wayne Ind (licensed in Indiana in 1897), Civil War Veteran aged 93 died January 1, of chronic nephritis

Charles Sturgill, Garrett, Ky University of Louisville Medical Department, 1908 aged 49 died Dec 26, 1935 of heart disease

Charles Felix Dale, Louisville Ky University of Louisville Medical Department, 1906, aged 53 died January 2, of pneumonia

Edmund Shields @ Cincinnati Medical College of Ohio, Cincinnati, 1889, aged 71, died, Dec 30 1935, of coronary sclerosis

Corlin Heath Snyder, Montebello Calif Michigan College of Medicine and Surgery, Detroit, 1893, aged 80 died Dec 16 1935

Christina Scott Clegg, Los Angeles, College of Physicians and Surgeons Keokuk Iowa 1897, aged 75 died Dec 11, 1935

Robert Young Fisher, Parsons Tenn (licensed in Tennessee in 1889), aged 67 died, Dec 30, 1935, of heart disease

Joseph Huberti, Fox Lake Wis, Rush Medical College Chicago 1888, aged 78 died Dec 27, 1935 of myocarditis

Correspondence

IONIZATION TREATMENT FOR HAY FEVER

To the Editor—I have read with interest the article "Disappointing Results from the Ionization Treatment for Hay Fever," by Dr Maximilian A Ramirez (THE JOURNAL, January 25 p 281) I am at a loss to understand why Dr Ramirez secured such poor results from a method that has been satisfactory not only to me but to many leading rhinologists of this country I know there is no way of guaranteeing to cure anything about the human body, but the results that I have secured from my own method as compared with results obtained by the use of pollen antigen, have been superior as far as it is possible to estimate from the statistics available Also, it is interesting to note that a large percentage of the patients treated by ionization had previously received treatment, by injection of pollen extracts, at the hands of some of our most prominent allergists Figures compiled early in 1935 from the records of the users of ionization treatment showed an average of 80 per cent cures

H L WARWICK, M D, Fort Worth, Texas

REVERSE COLLES FRACTURE RATIONAL TREATMENT

To the Editor—During the past year there have been several articles in THE JOURNAL regarding the reverse Colles, or Smith, fracture Webb and Shemfeld (June 29, 1935, p 2324) reviewed the literature and presented a case of their own in which open reduction was required They stated that they had been unable to find a report of a successful closed reduction and thus concluded that all fractures of this type should be regarded as cases for primary operation Raymer (Dec 28, 1935 p 2150) presented a case of Smith fracture which was treated successfully by closed reduction His conclusion was that this method should be tried in all reverse Colles fractures and that operation should not be resorted to until several attempts at manipulation have proved unsuccessful In the same issue Bettman and Tannenbaum (p 2151) presented a reverse Colles fracture treated by closed manipulation and stated that they had had several other similar cases Their conclusion, like that of Raymer was that manipulation should be attempted in all cases prior to operative intervention

I cannot fully agree with either side of the controversy as it has been stated, for neither side has taken into consideration the point which I consider of greatest importance in determining the method of choice for handling these fractures There are reverse Colles fractures in which closed reduction is quite likely to prove successful There are others—and they are in the majority—in which one can safely predict that it will fail The vital factor is the direction of the fracture line If it is wholly or partly transverse, as it was in the case reported by Raymer and in that reported by Bettman and Tannenbaum, closed reduction is quite likely to prove successful If it is oblique, as it was in the case reported by Webb and Shemfeld operation is the only hope of obtaining adequate reduction

Colles and Smith fractures are both fractures of the lower end of the radius the distinction being that in the Colles fracture the lower fragment is displaced posteriorly while in the Smith fracture it is displaced anteriorly The Colles fracture is produced usually by a blow on the palm of the hand, forcing the wrist into hyperextension and breaking the radius by indirect violence just above the widened lower end of the bone It is almost always transverse, and when properly and completely reduced by manipulation it tends to remain in position

The Smith fracture is produced usually by a blow on the back of the hand, forcing the wrist into hyperflexion and breaking the radius also by indirect violence. The anterior surface of the bone usually gives way just above its widened lower end but the posterior cortex often breaks much closer to the joint, causing a fracture line which runs diagonally downward from the anterior to the posterior surface of the bone. Such a fracture may be reduced by traction, but it will not stay in position unless the traction is maintained. Attempts to hold it in place by ulnar deviation and dorsal flexion of the wrist usually result in tilting the short lower fragment without accomplishing their purpose.

On analyzing the mechanics of the breaking force in relation to the size and shape of the lower end of the radius, one can understand why the Colles fracture is nearly always transverse while the reverse Colles is often oblique. When the wrist is forced into hyperextension the strain comes on the anterior surface of the bone, which gives way at its weakest point. This is just above the widened lower end of the bone. As the force continues to act, the strain continues on the still unbroken bone until it is fractured completely. The natural tendency is for the break to continue at the same level at which it started, causing a transverse line of fracture. When the wrist is forced into hyperflexion the strain comes first on the posterior surface of the bone, which gives way at its weakest point. The posterior surface of the lower end of the radius is not reinforced close to the joint as is the anterior surface. Thus the break in the cortex may occur at a point very near the joint. As the force continues to act the strain continues on the still unbroken bone until it is fractured completely. The natural tendency is for the break to continue at the same level at which it started, but this tendency is offset by the fact that it encounters thicker and stronger bone as it progresses toward the anterior surface. Before sufficient strain has been placed on this stronger area to break it, the weaker bone proximal to it gives way, and the break thus progresses proximally as it progresses dorsally. This causes a fracture line which is oblique rather than transverse.

It is known from experience with fractures elsewhere in the body that the difficulty of reduction and retention depends largely on the obliquity of the line of fracture and to a much lesser extent on the direction of displacement of the fragments. In this respect fractures of the lower end of the radius are no exception. A reverse Colles fracture is difficult to reduce not because the lower fragment is displaced anteriorly but because the fracture line is usually more or less oblique. When the patient has the good fortune to break his radius transversely no matter what direction the lower fragment is displaced he can be treated by closed manipulation. When the fracture line is sufficiently diagonal he will require open reduction whether the lower fragment lies anterior or posterior. In short it is not the name of the fracture that makes it irreducible by closed methods nor the direction in which displacement occurs but the obliquity of the fracture line.

In order to obtain a good functional result in fractures close to a joint it is necessary that good anatomic reposition of the fragments be secured with as little trauma as possible. This fundamental precept is particularly applicable to fractures close to the wrist joint. Bearing this point in mind one must choose the method of reduction that will be most likely to succeed. I do not believe it is any better surgery to make several attempts to achieve a closed reduction in a case that is obviously operative than to rush the patient into an operation in a case in which closed reduction is quite likely to be successful. I do believe that one can judge fairly accurately which cases are undoubtedly operative and which are nonoperative by studying the roentgenogram paying particular attention to the obliquity

of the line of fracture. Naturally there will be borderline cases, in which it is not possible to decide whether or not closed reduction will succeed. These cases should have the benefit of one conscientious effort at closed reduction under fluoroscopic control. It can then be decided whether or not open reduction will be required.

I would suggest, therefore, that in all cases of fracture about the wrist, whether Colles or the reverse, the physician should study carefully the line of fracture as shown in lateral x-ray films and base his judgment of the correct method of reduction on the degree of obliquity of the line of fracture, reserving for primary open operation without preliminary manipulation those which show a totally oblique fracture line and attempting a closed reduction in those in which the line of fracture is wholly or partially transverse.

W. STUART WOOD, M.D., Decatur, Ill.

BURNING TONGUE

To the Editor—May I take the liberty of remarking that the answer to our colleague's query (*Queries and Minor Notes*, THE JOURNAL, February 1, p. 403) on burning of the tongue is somewhat incomplete.

If reduction in the volume of the tongue is really indicated, the use of the multiple cautery or the removal of a wedge-shaped piece of tongue tissue will probably help accomplish this. It is evident, however, that it will not favorably affect either the burning question in the mind of the attending physician or the burning in the tongue of the patient. Burning tongue, in the absence of acquired gross pathologic changes in the mucous membrane, is observed in such varied states as simple glossodynia, glossodynia exfoliativa, the avitaminoses, the anemias, the irritated and inflamed grooves of a scrotal tongue, and Laim's disease (burning due to the presence of dissimilar metallic dentures).

It appears to me that the patient concerning whom the Kentuckian writes has in all probability a congenital macroglossia (of acromegalic lymphangiomatous or unknown nature) with, and this is not unusual, an associated grooved tongue. The lingual imprints of the dental arch are commonly observed in the flabby tongue of the grosser manifestations of this disorder and under these conditions is sometimes termed lobulated tongue. It is stated that the patient has deep "fissures"—probably meaning deep furrows, since fissures usually connote a break in the epidermis—also usual with this complaint. Given a grooved tongue in which the furrows are very deep, the irritation and burning which occasionally develop are usually due to the fact that food collects deep in such sulci and undergoes decomposition, and the products of this decomposition, perhaps with superadded infection, produce the irritation and the burning. If the lips of such affected grooves are separated and their bases thoroughly cleansed at regular intervals with warm sodium perborate solution, rapid improvement generally follows, as the late Dr. Walter Highman of New York pointed out several years ago. Aside from those already noted, there are of course other causes for burning sensations in the tongue such as those connected with Sluder's lingual tonsillitis, Costen's temporomandibular joint derangement, cancerophobia and lingual papillitis. The doctor speaks of "white blebs" forming on the borders and tip of the tongue. Is it possible that he has designated as "white blebs" the whitish areas (leukoplakia of mechanical origin) that one often sees on the borders of such tongues? One other point in connection with the case is that the examination for the cause of any existing macroglossia is incomplete without serologic studies for syphilis.

SIGMUND S. GREENBAUM, M.D., Philadelphia

OSTEO ARTHRITIS OF SPINE

To the Editor—My mother aged 68 until a year and a half ago had unusually good health. Her present illness began at that time when she began complaining of vague symptoms characteristic of chronic cholecystitis. I advised her to go to a hospital where a series of roentgenograms revealed a low grade chronic cholecystitis and osteoarthritis of the spine. Her blood pressure at that time was 100 systolic 60 diastolic. She had no jaundice at any time in her life. She was markedly emaciated but had considerable subcutaneous fat. Her blood picture was characteristic of a secondary anemia. The predominant symptoms that caused her most discomfort were intermittent dull aching pains in the region of the navel and lumbosacral region of her back varying from an hour to five hours at a time associated with distention following meals. On the advice of the hospital doctor she was sent home. Another doctor performed a cholecystectomy. She got along quite well but the abdominal and back pain symptom recurred. This pain has been unbearable. June 29 she fractured her left femur at the intertrochanteric point and has gotten along quite well. Of course this is incidental but she persists to complain more of this abdominal and back discomfort than all other previous symptoms combined. I should appreciate any reference or information which you might offer that would be helpful to her.

M D Ohio

ANSWER—The osteo-arthritis of the spine may be incidental and may not be causing the symptoms that might be attributed to it. Every effort should be made to eliminate carcinoma of the stomach, pancreas, liver or duodenum. It is possible that the fracture of the femur was pathologic.

Osteoarthritis of the lumbosacral region would not cause pain in the region of the umbilicus. It would be more apt to work the other way, i. e., osteoarthritis of the twelfth thoracic and first and second lumbar vertebrae would give pain at a lower level in front. In radicular cases the pain is referred to an area lower down, usually following the general direction of the ribs.

The best way to prove whether osteo-arthritis is an important factor in this case is the therapeutic test of treatment in the nature of bed treatment with boards under the mattress, either head and belt traction or a slightly curved Bradford frame, and physical therapy consisting of gentle massage, heat, and diathermy, if the patient responds favorably.

It is being taken for granted that gross foci have been eliminated from the picture, such as the teeth, tonsils and the genito-urinary and gastro-intestinal tracts.

DANGERS IN USE OF ETHYL OR HIGH TEST GASOLINE

To the Editor—A question has arisen as to whether employees of the company with which I am connected using ethyl gasoline or any other high test gasoline in the washing of automobile parts such as gears were subjecting themselves to any extra hazard more than they would by using the ordinary low test gasoline. I am unable to find any literature on this subject.

W G Hess MD Holtwood Pa

ANSWER—All or many of the gasoline station pumps dispensing ethyl gasoline display a sign reading 'Contains lead (tetra ethyl) and is to be used as a motor fuel only not for cleaning or any other use. Avoid spilling.' This familiar sign apparently is the outgrowth of recognition that this form of lead unlike inorganic forms, may enter the body through the skin and thus cause lead poisoning. However, the quantity of tetra ethyl lead per gallon of gasoline is so low (approximately 16 cc) that poisoning by absorption through the skin is not likely. Of this Kehoe and his associates (*J Indust Hyg* 16 100 [March] 1934) state "It penetrates the unbroken skin. Indeed skin absorption alone may result in the rapid production of acute illness and death in experimental animals. From a physical point of view the volatility of tetra-ethyl lead is low, but in toxicological terms it is dangerously high, since at ordinary temperatures air saturated with its vapor contains approximately 5 mg of lead per liter." At another point they state: Their [garage mechanics] exposure to lead in exhaust gas of automobiles burning leaded gasoline is greater therefore, than any other group of persons in the community. Further the handling and the spillage of gasoline the adjustment of carburetors and the repair of other parts of the car often involve skin contact with gasoline and with lubricating oil which may contain minute amounts of tetra-ethyl lead." However these investigators maintain that no evidence is at hand showing lead absorption following skin contact in the ordinary

course of the distribution and use of tetra-ethyl lead. Notwithstanding, it is pointed out that the use of ethyl gasoline for metal washing serves no known useful purpose not obtained through the use of ordinary gasoline. Any such practice as a routine procedure may not be condoned. With respect to 'other high test gasolines' it is pointed out that added toxicologic significance is to be attached to them when used for metal cleaning purposes if these gasolines are more readily volatile than 'ordinary low test gasoline.' Particularly is this true if the fuel is or contains coal tar benzene (benzol). The vapors of all gasolines, naphthas and benzines are toxic and similarly so except that the readier the volatilization the greater the prospect of damage, other things being equal. From the point of view of the physician, preference is extended to the high boiling petroleum derivatives for cleaning purposes.

MUSCULAR ATROPHY

To the Editor—I have a case of muscular atrophy that seems to defy classification. A housewife aged 21 married three years offers as her chief complaint weakness and general wasting of her muscles. The condition started one year ago. At that time she was six months pregnant and gave birth to a dead fetus. Together with this she developed what she called a severe cold sinus trouble and painful discharging ears. This condition lasted about a week and was followed by numbness in the feet and hands which in turn was followed by a stiffness in the legs. She was unable to walk and has been in bed since. Then began a gradual wasting of the small muscles of the hands and feet and a progressive involvement of both upper and lower extremities. Throughout the whole year she has been having pain in the legs. Her only previous illness was that of measles during early childhood she always enjoyed good health and never noted any weakness in her limbs. There is no history of muscular atrophy in any of the members of the family. Her mother and father brothers and sisters are all living and well. Her only pregnancy was the one mentioned. From her family physician it was learned that at the onset of this condition she was emotionally unstable. She cried easily worried considerably and her tendon reflexes at that time were generally exaggerated. The patient is quite happy and answers questions intelligently. There is a general atrophy of the muscles with the exception of the face and neck. The head does not fall forward. The muscles of the thorax and abdomen show considerable atrophy but not so marked as that of the extremities. The thyroid is visibly and palpably enlarged. The upper extremities show the simian type of hands. The feet show a similar type of wasting with the toes flexed. There is a glossy appearance of the skin over the hands and feet showing trophic disturbance. There are some decubital sores over the sacrum. The tendon reflexes in both upper and lower extremities are absent. The Babinski reflex is normal. The patient is able to move both hands and feet but the toes and fingers are contracted and almost entirely flexed. There is no fibrillary twitching. A definite lateral nystagmus is noted. The pupils are equal and regular and react to light and in accommodation. With the exception of a hypersensitivity about the feet there is no sensory disturbance. There is no loss of sphincter control. The laboratory report shows 3 380 000 red blood cells 95 per cent hemoglobin 3 850 white blood cells 57 per cent polymorphonuclears 32 per cent small lymphocytes 2 per cent large lymphocytes 3 per cent eosinophils and 4 per cent myelocytes. The blood Wassermann reaction is negative. The spinal fluid Wassermann test shows 2 cells per cubic millimeter. There is a very faint trace of globulin. The colloidal gold curve is normal. The Wassermann reaction is negative in all concentrations. Spinal fluid examination was done on three different occasions during the past year. The basal metabolic rate is -12. Roentgen examination shows no evidence of articular changes. The small bones of both extremities show osteoporosis. I will appreciate your opinion on this case.

M D Pennsylvania

ANSWER—The record of the patient in this case is seemingly clear. The onset of the illness during pregnancy especially as this coincided with a period of a severe cold, sinus trouble and discharging ears suggests the definite possibility of a toxic infectious process. Conditions of this type have been described under several headings such as neuritis, infectious polyneuritis and neuritis of pregnancy and seem to fit the case satisfactorily. The absence of fibrillary twitchings in the muscles probably rules out chronic poliomyelitis. The pain in the legs, the glossy skin, the loss of reflexes and the hypersensitivity about the feet are quite in keeping with a polyneuritic disturbance. It is true that, as a rule, there are more sensory disturbances than were noted in this patient but the degree of sensory loss is exceedingly variable in these cases.

It would have been interesting to know the exact amount of total protein in the spinal fluid, as in cases of so-called neuritis the total protein is markedly increased. Occasionally in cases of this type there may also exist a retrobulbar neuritis.

If the diagnosis of a neuritis is correct, the patient should slowly improve. It is advisable to eradicate all possible foci of infection. The patient should be placed on a high vitamin diet as occasionally a vitamin deficiency is an element in the production of the symptoms. Baths, massage and supportive measures to the affected parts should be employed over a protracted period of time.

MILK FEVER

To the Editor—Dr De Lee in his textbook of obstetrics emphatically states that there is no such thing as milk fever. Recently I had a patient under my care whose temperature rose to 102 F on her third postpartum day. There was no sign of infection in the genitalia or in any other part of the body. The breasts were large, hard, congested and painful. The breast pump was used once and an ice bag applied continuously. About three hours later the temperature dropped to normal, remaining so the rest of her stay in the hospital. On what grounds could you explain this rise and drop of temperature?

M D Ponce Puerto Rico

ANSWER—In olden times infection was so common after delivery that midwives and doctors had to present an alibi. "Milk fever" was such an alibi and was said to be due to a turning in of the milk. Indeed, the postmortem examination of women who died of this disease often showed coagulated milk and cream in the peritoneal cavity and in the joints, which is now recognized as pus. With the generalization of antiseptic and aseptic measures, this form of "milk fever" has disappeared. Thousands of women have immensely engorged breasts so bad sometimes that they cannot bring their arms to their sides and yet they have no fever.

Theoretically, one might imagine that resorption of milk from engorged breasts, especially if injured, might cause fever, but there is very little milk in engorged breasts. Milk is formed as it is drawn and then the lymphatic and vascular engorgement subsides.

Injection of milk has been used to produce a foreign protein reaction. Mild cases of infection that can cause a temperature of 102 or 103 often occur without a single local symptom or finding on examination such as a mild parametritis or endometritis, and such an explanation, in all probability, applies to the case in question.

USE OF BENEDICT'S SOLUTION FOR DETERMINATION OF SUGAR IN URINE

To the Editor—In our laboratory we have been using Benedict's qualitative solution for the routine testing of urines for sugar purchased in 500 cc quantities from the LaMotte Chemical Company. In view of the fact that with approximately 0.5 cc—from 8 to 10 drops—of the urine I obtained what one might call false positives in almost every urine tested I sent to the Arthur H. Thomas Company and purchased volumetric pipets calibrated to expel exactly 0.5 cc when emptied by blowing. Thereafter I had my technician measure exactly 5 cc of Benedict's solution into a pyrex test tube following which exactly 0.5 cc of the urine to be tested was blown from the volumetric pipet into this tube containing the LaMotte Company's Benedict's qualitative solution. Even though we have just recently purchased another batch of 500 cc 95 per cent of the urines tested will turn faintly grass green and there will settle at the bottom after cooling spontaneously at room temperature a grayish flocculent precipitate seemingly enmeshing a small amount of a yellowish powdery precipitate causing the tip or the bottom of the test tube when looked at from the bottom after the sediment has settled to give somewhat the appearance of a small quantity of reduced copper. When shaken again the precipitate disseminates itself throughout the rather bluish, non-reduced copper solution and loses the reduced copper precipitate look and assumes more the appearance of a flocculent, heavy, grayish precipitate. The remainder of the solution then assumes once more somewhat of a grass green hue. It is needless for me to enter a long rehash as to the various constituents in the urine that give precipitates of various types that are not truly due to the presence of dextrose. There is a desirable aspect to having a solution that is sufficiently delicate for clinical purposes which gives a sharp clear cut end point in negative specimens. I mean by this urines that are negative having the solution remain clear and brilliantly blue as it should be after the test has been properly carried out. I wrote asking why I should obtain such an overwhelming number of specimens difficult to interpret—in fact 95 per cent. I am wondering what your chemists think of such substances and from whom it might be possible to obtain a Benedict's solution more prone to give a sharp clear cut end point reaction rather than such an overwhelming number of questionable tests. This has become such a source of exasperation that I am looking for a means of escape.

M D Indiana

ANSWER—The qualitative test of the urine for sugar is best performed with Benedict's solution by means of the following technic:

1. Add 0.25 cc (five drops not more) of urine to 5 cc of Benedict's solution in a test tube (about 1 inch in a test tube three-fourths inch in diameter). Shake the test tube to mix the solutions.

2. Heat for one or two minutes over a Bunsen burner or place in boiling water for five minutes.

3. Allow to stand before examining.

No reduction leaves the solution the usual transparent blue and indicates that sugar is not present in pathologic quantities. A translucent greenish blue flocculation settling as a grayish precipitate will appear when the urine is very concentrated with a high specific gravity. This gray precipitate is due to urates and not to sugar. It may also occur when an excess

of urine is added, which is a frequent technical error. If albumin is present in large amounts it may interfere with the precipitation of copper and should be removed by acidifying with acetic acid, boiling and filtering.

Reduction shows opacity with a yellow or red precipitate. The amount of sediment depends on the percentage of sugar present. A green turbidity with slight yellow precipitate at the bottom indicates from 0.1 to 2 per cent sugar. A yellow or red precipitate that settles, leaving a clear fluid, indicates over 3 per cent of sugar. A flocculent precipitate that does not settle rapidly is due to other substances than sugar.

Any laboratory can prepare its own Benedict's solution according to the following formula:

Benedict's Copper Sulfate Solution

Copper sulfate (pure crystallized)	17.3 Gm
Sodium citrate	173.0 Gm
Sodium carbonate (crystallized)	200.0 Gm
(or 100 Gm of anhydrous sodium carbonate)	
Distilled water	to make 1000.0 cc

Dissolve the copper sulfate in 100 cc of distilled water with the aid of heat. Dissolve the sodium citrate and carbonate in 700 cc of distilled water, heating if necessary. Then pour in the copper sulfate solution rinsing the container twice with about 25 cc of distilled water. When cool, dilute to 1,000 cc with distilled water.

CONGENITAL PULMONARY STENOSIS

To the Editor—A boy aged 7½ years weighing 61 pounds (27 Kg) and standing 51¼ inches (130 cm) tall has been affected with cyanosis, shortness of breath, weakness and a constant tired feeling on exertion since birth. The cyanosis is most pronounced in the lips, fingers and toes. Physical examination is essentially negative without abnormalities except for an enlarged heart downward and to the left. The point of maximum intensity is located in the seventh interspace one-half inch to the left of the anterior axillary line. The transverse diameter of the heart at the apex is 6½ inches; the transverse diameter of the heart at the base 4 inches. There is a systolic murmur heard over the entire heart but more pronounced at the pulmonary area. Functionally the heart shows good compensation; the only impairment being marked cyanosis and weakness on exertion. There is no pain over the heart, discomfort occurring only on exertion. There is no edema of the extremities. The second pulmonary sound is weakened and there is a slight systolic thrill present. The right side of the heart is enlarged. A diagnosis of congenital stenosis of the pulmonary valves of the heart has been made. Kindly state method of treatment and prognosis. Can anything be done to remedy this condition? The tonsils and adenoids were removed at 1 year of age. No childhood diseases have occurred except measles. The health is good. He is a very active child.

M D New Jersey

ANSWER—The boy is undoubtedly suffering with congenital heart disease, and the signs and symptoms as given all point to a diagnosis of congenital pulmonary stenosis. In general the clinical diagnosis of the exact lesion in any given case of congenital heart disease may be extremely difficult, and many astute clinicians will commit themselves only to a presumptive diagnosis of the exact nature of the lesion. Experience at the necropsy table corroborates the fact that the signs and symptoms of congenital heart disease may often prove misleading. Nevertheless, the prognosis in any given case will naturally depend on the nature and extent of the organic lesion. Granted that in this case the condition is a pulmonary stenosis, it would be extremely helpful to know whether the stenosis is uncomplicated or is combined with a patent foramen ovale or with an intraventricular septum defect, or whether the stenosis is accompanied by a patent ductus arteriosus. It has been said that if the pulmonary second sound is feeble, the stenosis is uncomplicated or associated only with a patent foramen ovale. If the second sound is normal or slightly accentuated, the stenosis is said to be associated with a septum defect, and if the second sound is greatly accentuated, the stenosis is said to be associated with a patent ductus arteriosus.

According to Maude Abbott the prognosis, as far as duration of life is concerned, is highest for those patients in whom the pulmonary stenosis is uncomplicated by other lesions. In a number of cases analyzed by this author, twice as many individuals lived over twenty years in whom the pulmonary stenosis was accompanied by a closed ventricular septum as did those in whom the stenosis was accompanied by a patent septum defect. In general it may be said that in patients with congenital heart disease there is a tendency to develop pulmonary complications. These patients are said to be liable to tuberculosis especially in the adolescent years. Pertussis is poorly withstood, although the acute exanthems are generally fairly well borne. A superimposed bacterial endocarditis is said to be of high incidence in these patients. In general it may be said that the prognosis is unfavorable in proportion to the degree of cyanosis, dyspnea and palpitation.

The treatment of congenital heart disease can be only symptomatic and should include attention to the state of nutrition precaution against overexertion and general hygienic management. In advanced cases subject to intense cyanosis and cardiac pain, morphine or glyceryl trimtrate may be needed. Inhalation of oxygen has been used to relieve dyspnea. In attacks of syncope, camphor or caffeine hypodermically may be needed. There is no known remedy for congenital pulmonary stenosis.

HEART SENSITIVITY TO TOBACCO

To the Editor—Until recently I had been smoking for twenty five years. Lately however a few puffs on a cigaret greatly accelerate my pulse rate probably to 140 a minute along with a great deal of bodily uneasiness. I may say terror. I have a chronic mitral stenosis with some enlargement of the heart to the right but the lesion seems to be well compensated. I am 43 years of age. Several weeks ago after my usual day and night of smoking my heart action became extremely rapid and irregular. There was some doubt whether there was auricular fibrillation. After I discontinued tobacco for a few days my usual pulse rate dropped from 90 or more to normal or less. Today I tried to smoke a demicotized (Sano) cigaret manufactured by Health Cigars Co. Inc. New York. When the usual tachycardia began I desisted. Skips and extrasystoles are my usual fare. Is it possible that the 1 per cent or less of nicotine in the aforementioned demicotized cigarets is sufficient to irritate my already nervous or irritable or tobacco heart? The thought is suggested that tobacco may contain some noxious principle or property besides nicotine. Surely my imagination would not speed up my heart after smoking the demicotized cigars. Is there any way of combating this cardiac sensitivity to tobacco? Are bromides in order three or four times a day? I dislike intensely having to give up tobacco. I may add that the mitral stenosis with cardiac (right hearted) enlargement has been proved by percussion auscultation the fluoroscope and the electric cardiograph. I have had about twenty years of uninterrupted strenuous work with scarcely a day of rest or recreation. But what of tobacco?

M D Althura

ANSWER—Although considerable research work has been done on the subject, the possible toxic effects of various components of tobacco and tobacco smoke have not been definitely established with the exception of the effects of nicotine. There are considerable data to show that tobacco smoking does have an immediate stimulating effect on the sympathetic nervous system as does nicotine but this varies greatly with different individuals. Also certain sympathetic nerves may give, selectively, a much greater response than others for example the vasomotor nerves, the gastric secretory nerves or the accelerator nerves of the heart. Opinion is divergent regarding any other direct effect on the heart or on the coronary circulation. Analysis has shown that the so called demicotized Sano cigarettes contain at least a third as much nicotine as ordinary cigarettes, which contain only from 2 to 2.25 per cent so that if an individual's sympathetic nerves are easily affected by nicotine the less than 1 per cent might be sufficient to produce a response.

A reasonable hypothesis in the case in question is that in the presence of mitral stenosis of some years duration, the threshold of irritability of the myocardium has finally become lowered to the point at which stimulation of the accelerator nerves by the regular dose of nicotine finally produces an abnormal response. Digitalis quinine barbiturates and bromides could be tried one at a time in an effort to reduce both the myocardial and the sympathetic irritability but the simplest and possibly the only effective procedure will be complete abstinence from tobacco.

COLLOIDAL SULFUR IN ARTHRITIS

To the Editor—I am much interested in colloidal sulfur therapy for arthritis and neuritis. What do you think of it? Where can I secure literature on sulfur treatments? What firms make colloidal sulfur? I have been told that the sulfur content of the system can be determined only by the cystine content from the nails. Can you give me the laboratory technique and method of determining the cystine content of the nails? I am a sufferer from neuritis.

M D Ohio

ANSWER—Intravenous or intramuscular injection of colloidal sulfur has been used for some years in the treatment of chronic arthritis. Its employment has some enthusiastic advocates (Woldenberg S C *W Rec* 139 161 [Feb 21] 1934 Wheelton T F *J Bone & Joint Surg* 15 94 [Jan] 1933). The toxicity of such colloidal sulfur depends largely on its dispersion and the speed of intravenous injection. The greater the dispersion the greater the toxicity and the smaller the dose required. There is a distinct risk of anaphylactoid or colloidal shock (Hanzlik P J and Karsner H T *J Pharmacol & Exper Therap* 23 173 [April] 1924). The pharmacologic action of colloidal sulfur apparently is dependent on the formation of sulfur compounds with hydrogen the halogens and organic matter. Sulfur is also cathartic and tends to accel-

erate oxidation. There is some indirect evidence that sulfur increases the catabolism of proteins in the body. The effectiveness of colloidal sulfur in arthritis is probably more logically attributed to changes in certain ill defined metabolic processes than to any direct local effect on the inflamed tissues. Frequently there is a transient exacerbation of the swelling of the affected joints, which in some cases may be followed by improvement.

The technique for the determination of the cystine content of the nails was reported by M X Sullivan in Public Health Supplement 86 in 1930. The procedure is complex and requires considerable special equipment. Arthritic patients are frequently deficient in sulfur, according to Woldenberg.

HYPERSENSITIVITY TO TRICHOPHYTIN

To the Editor—A man aged 52 with a generalized urticaria of five months duration has been referred to me for sensitization tests. Associated with this condition there is present a fairly marked trichophytosis of both feet. Cutaneous and intracutaneous skin tests to about 200 varied extracts have been essentially negative with the exception of a marked (+ + +) reaction to trichophyton. Is it possible that desensitization to this may relieve his urticaria or is this perhaps incidental? Please advise also as to whether any known cases of urticaria with trichophyton allergy as an etiologic factor have been previously reported.

MAX EHRLICH MD Elizabeth N J

ANSWER—Dermatophytosis of the feet is so common in adults in the United States that it is quite possible that there may be no relationship between the fungous infection and the urticaria. However, cases of asthma, vasomotor rhinitis and urticarial hypersensitivity to trichophyton have been described, and specific reagins (Prausnitz-Kuestner antibodies) to trichophyton have been demonstrated in these patients.

If the patient's positive reaction to trichophyton is of the urticarial type (that is, if it manifests itself in a wheal and flare reaching its maximum at about twenty to thirty minutes after intracutaneous injection) it is likely to be of more significance in this case than if the usual forty-eight hour papular so-called tuberculin type reaction is meant. The latter type of reaction is the usual one to be found in persons who have, or have had, infections with fungi of the trichophyton group.

If the urticaria persists in spite of all classic therapy (Fantus Bernard Therapy of the Cook County Hospital Urticaria and Angioneurotic Edema *THE JOURNAL* Aug 24 1935, p 595) and if the patient presents the urticarial type of reaction to the trichophyton skin test careful desensitization with trichophyton is worthy of trial. The physician must exercise maximum precautions to avoid systemic reactions beginning with very small doses. The injections should be given at intervals of three or four days intracutaneously in ascending doses.

It would seem advisable to test this patient with oidiomycin as well and in case of an urticarial reaction to this fungus group combined desensitization with dermatomycin may be tried.

BLOCKAGE OF SALIVARY DUCTS

To the Editor—At present I have under my care two patients suffering from partial blockage—in one case of the duct of the parotid gland and in the other of the duct of the submaxillary gland. As a result of this blockage the glands will increase in size to two or three times their normal size and then the blockage seems to be overcome by the increased pressure and the swelling subsides with the discharge of large quantities of salivary material. Would you kindly outline the treatment for these conditions? I think the blockage is due to salivary concretions in the ducts.

M D Ontario

ANSWER—A good x-ray film of both the parotid gland and its duct and the submaxillary gland and its duct is the most definite and accurate method of determining salivary calculi. In the case of the submaxillary salivary gland a large intra-oral film should be placed over the teeth in the lower jaw, touching the occlusal surfaces on both sides and the tube should be directed from below. This will give a clear view of the gland and its duct without any bony interference. In securing a film of the parotid gland, the film should be placed on the buccal surface of the teeth and placed as far back as possible, and in like manner the field will be roentgenographed without any bony interference. It is sometimes helpful to place a small flexible silver probe in the parotid duct before the film is made. This will indicate the portion of the duct that is free and if there is a stone it should be located at or beyond the end of

the probe. From the description it would seem that there must be some physical interference with the flow of saliva, and this in most cases is a salivary stone. Usually a stone in the submaxillary duct is easily removed from inside the mouth, but, if the stone is located in the gland, the gland will have to be removed.

ALOPECIA DURING PREGNANCY

To the Editor—I have a patient aged 35 who is now two months pregnant. She has had four previous pregnancies three of which terminated in normal deliveries. The children are now 8, 7 and 4 years of age respectively. The third pregnancy resulted in a miscarriage at three months due to overwork. This happened five and one half years ago. During the fourth month of the fourth pregnancy the patient within one week's time lost all the hair from all parts of her body: scalp, eyebrows, eyelashes, axillary and pubic areas. This happened approximately four and one half years ago. About two years ago the hair began to reappear and now is almost normal in its texture, length and distribution. The humiliation of the loss of hair caused the patient to remain almost a recluse in her home for about three years. She is now an extremely nervous type of individual weighing 110 pounds (49.9 kg) with no apparent organic lesions. Financial difficulties have prevented such laboratory procedures as determination of the basal metabolism rate and x-ray therapy of the skull. What would be the possibilities of the etiology of the loss of hair during pregnancy four and one half years ago? This was during the last pregnancy. Is this liable to happen with the present pregnancy? Taking all factors under consideration could one consider this an indication for therapeutic abortion? Please omit name and address. V D Kentucky

ANSWER—The rare occurrence of loss of all the hair during pregnancy is difficult to explain. It has been a general belief that during pregnancy there is an increase in the growth of hair on the body. More recent and better controlled experiments, however, have shown that there is no more rapid growth of hair during pregnancy than in the nonpregnant state. There may be a pituitary factor involved in the present case but this cannot be proved. It is likewise impossible to say whether or not there will be a recurrence in the present pregnancy. In view of the mental upheaval caused by the loss of hair and the length of time it took for the hair to return there is some justification for interrupting pregnancy at the present time. Regardless of whether or not the gestation is terminated, the patient should be instructed in one or more reliable methods of contraception.

APPLICATION OF X-RAYS IN CANCER OF BREAST AND TO OVARIES

To the Editor—Recently I removed a growth or tumor from a woman's breast the size of a chicken egg. The pathologist reported a highly malignant scirrhous carcinoma. The woman aged 40 had had the tumor about seven months. The radiologist advised several high voltage treatments following the surgical removal of the tumor. These were given but made the patient quite ill the following day with an upset stomach and pain in the breast. It has been suggested to me to administer high voltage roentgen therapy to the ovaries to bring on the menopause and thus put the affected breast at rest. Do you consider the latter procedure necessary or advisable? The patient dreads further roentgen treatments because of the unpleasant after effects. M D Illinois

ANSWER—Roentgen therapy of the breasts and adjacent tissues is almost imperative if one hopes to obtain a permanent cure of a cancer after simple excision without radical removal of the breast. Nausea and local discomfort incident to such roentgen therapy are sometimes distressing, but these symptoms soon disappear and should be endured.

Roentgen therapy to the ovaries has no place in cases of cancer of the breast. It is true that the artificial menopause just as the natural menopause is followed by atrophy of the breasts but cases in which it is permissible to resort to radiotherapy to produce menopausal atrophy of the ovaries for the purpose of inducing shrinkage of the breasts must be rare indeed.

NAIL BITING IN CHILDREN

To the Editor—I have been asked by several mothers as to the proper treatment for nail biting in children under 4 years of age. Some of these children tolerate and even appear to relish several of the more common bitter preparations that are painted on the skin. Can you advise me of some effective agent? M D Illinois

ANSWER—Nail biting in children should be looked on as a nervous habit due to fatigue caused by excessive physical exercise by increased mental exertion at home or at school by insufficient sleep and rest or not infrequently by a nagging environment. Some children acquire the habit by imitation while others develop it on account of a hereditary neuropathic constitution. In a state of physical or nervous exhaustion a variety of nervous symptoms may occur. One child sucks his thumb another bites his nails while still another masturbates.

The treatment by applying bitter substances to the fingers or the use of splints or appliances is of no avail. It is equally useless to scold or shame the child. It is a better plan to attempt to improve the general hygiene of these children, to correct the overstimulating attentions of parents and friends, and to provide for sufficient sleep and rest, as well as to prohibit the reading of exciting bedtime stories. The child should be allowed to indulge only in so much physical and mental exertion as to avoid fatigue. Most of these children will recover from the habit if these general matters are attended to and if the attitude toward them is one of disregard and unconcern.

NERVOUS SENSATIONS IN LEGS IN ANEMIA

To the Editor—Have you any suggestions that might be of value in so called nervous feet? A man suffering from easily controlled pernicious anemia has had nervous sensations in the back of the thighs down the calves for many nights so that he cannot sleep. Heat and cold are apparently of no avail, and frequently he finds it necessary to resort to phenobarbital. M D, California

ANSWER—Besides intensive antianemia therapy (liver, liver extract or desiccated hog stomach) certain physical therapeutic measures, such as active and passive exercise of the legs and back and massage of the legs and back may be tried daily. Mild counterirritants (e.g., alcohol or 1 per cent menthol in alcohol) may be rubbed on the skin of the lumbar region and the legs at bed time. A pad (a folded towel, for instance) placed so as to support the lumbar curve while the patient lies in bed may be used. If the patient is ambulatory, attention should be given to the arches of his feet, efficient supports being used if necessary. Phenobarbital or acetylsalicylic acid is necessary in some patients. The urine should be studied repeatedly for evidence of retention or of cystitis. The group of symptoms may resist treatment and occasionally, although rarely, may be the precursor of progressive spastic contraction of the legs. It should be remembered, however, that this condition may be present in other diseases than true pernicious anemia.

TREATMENT OF SYPHILIS WITH HEART DISEASE

To the Editor—Would it be advisable to treat a patient aged 19 who has secondary syphilis, mitral stenosis with regurgitation and moderate cardiac hypertrophy with neoarsphenamine and a bismuth compound or just continuous treatment with the bismuth compound alone? Please omit name. M D Montana

ANSWER—It is improbable that the heart is involved this early. If the correspondent is certain that it is not, there is no reason why he should not go ahead with the routine treatment. Treatment should be continuous until there is a negative Wassermann and Kahn reaction, and the patient should be kept under observation always, with repeated blood examinations. When there is any possibility of cardiac or vascular involvement, it is probably better to use the heavy metals for several months before using the arsenicals. Occasionally, when the heart or the aorta is definitely involved, the patient may be worse even with arsenic or a bismuth compound. This occurs only rarely. If the pulse rate increases under treatment or other cardiac symptoms appear, treatment should be discontinued temporarily. The heart condition must always be kept in mind first and treatment of syphilis is secondary. There is no rule, and it is a matter of judgment in each individual case.

INOCULATION OF DOGS AGAINST DISTEMPER

To the Editor—Will you be willing to give the scientific background of inoculating young dogs against distemper? Are the benefits from inoculation fully accepted? PERCY T. WATSON, M D Northfield Minn

ANSWER—Carre of Alfort (*Etude sur la maladie des jeunes chiens Rev. gen. de med. vet.* March 1905, vol 5, No 54) and later Lignieres (*Sur la maladie des chiens et le microbe filtrant de Carre, Bull. Soc. cent. de med. vet.* Nov 30, 1906) demonstrated by limited but convincing experiments that canine distemper was caused by a filtered virus. These were confirmed by Laidlaw and Dunkin, whose extensive researches were conducted under most exactly controlled conditions (the Field Distemper Council Report for June 1925, *Studies in Dog Distemper J. Comp. Path. & Therap.* 39 part 3 [Sept.] 1926, *The Prevention of Distemper Fields*, Nov 29, 1928).

Although biologic preparations for canine distemper were available in this country as early as 1913-1914, these early products were prepared from bacteria that are now known to be but secondary invaders following the infection with the primary causative agent the filtrable virus.

Biologic products prepared from the true causative agent, the filtrable virus, appeared following the investigations of Lock.

hart, Ray and Barbee (*J Am Vet M* 4 77 August 1925) The high degree of perfection attained in canine distemper biologicals of today, however, resulted from the researches of Laidlaw and Dunkin, which extended over a number of years Canine distemper vaccine and anticanine distemper serum prepared according to the principles laid down by Laidlaw and Dunkin are approved by the Bureau of Animal Husbandry for preparation under U S veterinary licenses

REMEDY FOR SERUM SICKNESS

To the Editor—Please give me the latest recognized treatment for serum sickness I have tried everything new that comes out in medical literature but I have not yet been able to give these patients the prompt relief they demand Please omit name
M D Louisiana

ANSWER—Epinephrine solution 1 1000 in doses of 0.1 to 0.2 cc injected intramuscularly usually gives prompt but temporary relief The dose may be repeated as often as required Magnesium sulfate in full doses several times daily, enough to produce diarrhea, is the remedy of second choice The systemic treatment may be combined with the local therapy of urticaria If the eruption is quite generalized, a warm bath prepared by dissolving a cup of sodium bicarbonate in the bath water is likely to be helpful Following the bath the skin should be dried completely and dusted freely with talcum powder, to which 0.25 per cent of menthol might be added For an eruption of more limited extent, calamine lotion with 1 per cent of phenol is likely to be satisfactory As a systemic analgesic acetylsalicylic acid in 0.3 Gm doses taken every two to four hours may be of advantage, if the itching is severe

DETECTION OF HISTAMINE

To the Editor—Will you tell me whether there is a practical test for histamine in the secretions (chemical)? If so where can I get the technique, or can you send it to me?
M D Chicago

ANSWER—A simple chemical method for the detection or determination of histamine in tissues and secretions has not been described Histamine can be detected by means of various modifications of the Pauly diazo reaction One of the simplest procedures is that of the late Gebauer-Fuelnegg as described by R G MacGregor and W E Thorpe (*Biochem J* 27 1394 1934) One cc of the solution to be tested is mixed with 1 cc of 0.5 normal sodium carbonate and to this is added 2 cc of a fresh diazo reagent made by mixing equal volumes of 0.125 per cent *p*-nitraniline in 0.1 normal hydrochloric acid and 0.37 per cent sodium nitrite If histamine is present a reddish yellow color forms reaches maximum intensity in one minute and then fades and becomes cloudy If a quantitative estimation is desired the color may be compared with permanent standards in a colorimeter and the maximum value recorded As little as 0.01 mg of histamine may be determined in this way Unfortunately, the test is given by histidine, tyrosine and other compounds Proteins and ammonium salts also interfere The removal of interfering substances is a time consuming procedure, and considerable skill is required to avoid loss of histamine The isolation and determination of histamine in feces and in cecal contents has been described by M T Hanke and K K Koessler (*J Biol Chem* 59 879 [April] 1924)

Somewhat less complicated methods have been developed particularly by Best and his collaborators at the University of Toronto Thus, MacGregor and Thorpe describe the isolation of histamine by electrodiagnosis With simplified extraction procedures however, the colorimetric determination does not appear to yield accurate results and the histamine is best determined by physiologic assay This can be done by comparing the fall in blood pressure of an etherized cat with the drop produced by a known amount of histamine The effect of other depressor substances in the extract is allowed for by testing the material again after treatment to inactivate the histamine

ACIDITY OF TOBACCO SMOKING

To the Editor—Will you please let me know whether there is any basis for the claim that the actual difference in acidity from various cigarettes is of any significance and whether acidity—or difference in acidity—has any effect on the smokers
M D New York

ANSWER—There seems to be no evidence that the acidity of tobacco smoke is of the slightest importance in relationship to the health of the smoker or to irritation of his throat by the tobacco

Moreover, there seems to be no evidence that the difference in acidity between the several leading brands of cigarettes is any greater than the difference in acidity between varying specimens of the same brand

Book Notices

Head Injuries By L Bathe Rawling M B B Ch F R C S Consulting Surgeon to St Bartholomew's Hospital London Cloth Price \$7.10 1 p 86 with 22 illustrations New York & London Oxford University Press 1934

This little book sets forth the author's impressions and opinions concerning some of the clinical phenomena observed in head trauma and the treatment of such injuries. It was written while the author was on vacation, away from all references, and is therefore "a book of personal experience, based on an interest of a lifetime in head injuries." As a result it is a short practical elucidation of the principles governing the management of the average skull fracture case, with much of the text devoted to the operative treatment of the craniocerebral complications requiring operations. Almost all workers in this field will agree with the author's indications for operating in cases of skull fracture. Many will agree with him that there is the occasional case when an exploratory subtemporal decompression is indicated. It is noteworthy that he does not dwell on or recommend subtemporal decompression per se as a method of treatment. His chapter on subdural hemorrhage and subdural hematoma is especially good. It describes a condition more frequently overlooked, with disastrous consequences, than is usually realized. His description of the middle meningeal hemorrhage is the classic textbook picture, which is less often observed in actual practice than is the atypical middle meningeal hemorrhage. The atypical cases therefore are the ones that really should be stressed if more of these middle meningeal accidents are to be diagnosed and saved. This author advocates the use of morphine in cases of head injury, which differs widely from the views of the majority of the authors on this subject in America. He shows clearly that he does not hesitate to use this drug in cases of brain operations, whereas most of the brain surgeons in the United States are strongly opposed to its use. He mentions the fact that in his experience recovery has occurred in only one case of head injury with Cheyne-Stokes respiration. It is the belief of many that the depressing effect of morphine added to the existing respiratory depression from the brain injury is a common cause of Cheyne-Stokes respiration. Without question, the author's views on the use of morphine will not meet the approval of many of his readers. It is interesting to note that he thoroughly believes in the use of lumbar puncture as a routine procedure for diagnostic purposes in all head injuries and yet condemns it as a therapeutic measure and quotes Dandy as being in agreement with this view. Dandy of course condemns even diagnostic punctures. A survey of the opinions of ten leading neurologic surgeons in this country disclosed that eight used lumbar punctures in treatment and believed, when indicated, that this was a life-saving procedure. Further, only two favored diagnostic punctures and none were in favor of the routine use of lumbar puncture. In spite of a few controversial points, such as this, the reader will find the book an interesting and exceedingly helpful treatise on head injuries. It is not written for the brain specialist but rather for the average physician or surgeon, who is being called on to treat these serious craniocerebral injuries more and more frequently, owing to automobile casualties. To him this book has a practical message.

The Theory of Emulsions and Their Technical Treatment By William Clayton D Sc F I C Chief Chemist and Bacteriologist Messrs Cross and Blackwell Ltd London Third edition Cloth Price \$8.00 Pp 404 with 91 illustrations Philadelphia P Blakiston's Son & Co Inc 1934

The definition of an emulsion as a system of two liquid phases, one of which is dispersed as globules in the other, immediately suggests the wide distribution of these systems in all biologic and technologic materials. In this edition of his well known treatise on emulsions, the author has thoroughly revised the text and extended it more than 50 per cent. More than half the volume is devoted to theoretical considerations of emulsions and borderline subjects, while the remainder deals with technical applications. The field covered is so vast that even a transcript of the table of contents fails to indicate the wide range of subjects treated. The book contains thirteen chapters dealing with dilute emulsions as oil hydrosols, the air/liquid interface, adsorption at liquid/liquid interfaces, emulsifying

agents, properties of emulsions, theories of emulsions, dual emulsions and inversion of phases, emulsions in biologic investigations, miscellaneous emulsions, the preparation of emulsions—basic principles, the preparation of emulsions—technical operations, deemulsification, and physical measurements in emulsions. In the chapter on biologic emulsions the author discusses such topics as the chylomicron emulsion, the parenteral administration of emulsions, and milk. This book is recommended to all those who are interested in acquiring a well rounded knowledge of the theory and practice of emulsions. In spite of the fact that the space devoted to discussions of specific biologic investigations is necessarily limited, the volume will be found stimulating by those workers in the biologic sciences who are in a position to apply a thorough understanding of the properties of emulsions to the study of some of the fundamental problems of protoplasmic structure and behavior.

La tuberculose ostéo articulaire. Evolution diagnostique de début et traitement. Par Jacques Calve. Avec la collaboration de M. Galland et M. Mozer. Bibliothèque de physiologie sous la direction de Leon Bernard professeur de clinique de la tuberculose à la Faculté de médecine de Paris. Paper. Price 50 francs. Pp 208 with 101 illustrations. Paris: Masson & Cie 1935.

Calve presents a complete description of the evolution of tuberculosis of the bones and joints, as well as the diagnosis and treatment of the disease. He calls attention to the fact that tuberculosis of the bones and joints is practically always preceded by a primary infection elsewhere in the body. On roentgen examination he often finds such foci of disease in the lungs, and on postmortem examination there is often definite evidence of disease in the lymph nodes of the hilum or the mesentery. The fact that the intradermal tuberculin test is nearly always positive is emphasized. After the primary lesion is established a bacillæmia occurs, at which time tubercle bacilli find lodgment in the bones and joints. After this has occurred there may be either the tendency toward destruction, resulting in ulceration and necrosis, or the tendency toward healing, resulting in a tissue reaction, which controls the disease. Considerable space is devoted to the diagnosis of tuberculosis of the various bones and joints and emphasis is placed on making the diagnosis early. The difficulties of such diagnoses are emphasized. General methods of treatment are considered, such as heliotherapy, medication and tuberculin treatment. The author also gives in considerable detail his methods of treating various lesions surgically. The book is profusely illustrated and will serve as a fine manual not only to those especially interested in orthopedics but also to those interested in tuberculosis in general.

Growing Superior Children. By I. Newton Kugelmass, M.D., Ph.D., Sc.D., Attending Pediatrician of the Bronx Street Hospital, French Hospital and Rockefeller Institute, New York. Cloth. Price \$3.50. Pp 568 with illustrations. New York & London: D. Appleton-Century Company, Inc. 1935.

The purpose of this book is to explain to parents how superior results can be obtained in the rearing of children. The individuality of the child and the necessity for individualization in care are emphasized. For the author the "average" child is nonexistent; the tempo of the child's development can "be modified in the direction of more wholesome development" and by superior care from birth "early developments can be accelerated two or three years." The book is divided into four sections dealing respectively with the new-born, the period of infancy, childhood and adolescence. In each of these sections the physical traits, the course of physical development, the nutritional needs, the prevention of physical and psychologic disturbances and the training in the intellectual, emotional and social spheres are dealt with. The author is quite specific in his discussion of the physical development and growth of the infant and young child and their nutritional needs. Feeding schedules for infants, balanced diets for older children, a special diet for constipation and similar explicit aids to parents are included. Habit training, descriptions of normal course of mental development and the cultivation of emotional stability are given much attention. The problems of the period of adolescence, physical, emotional and social, are given rather full treatment. Many schedules, tables and illustrations enrich the book. The author is to be commended strongly for his effort to present a conception of

the child as a developing organism in an environment that strongly influences the development. He views the child as a totality rather than from the too restricted point of view that characterizes many medical approaches to the child's problems. Physical, intellectual, emotional and social aspects of the child's developmental needs are properly related in this presentation.

Certain shortcomings must be noted. At times, rather dogmatic statements that might not bear the cold scrutiny of the author's own critical regard are made, particularly in sections dealing with the emotional life of the child. Some of these statements must of course be attributed to the author's effort to couch his work in terms understandable to parents, but in this field he is not always accurate and not always understandable. *viz* "The mental make-up of the child is predestined at conception" (p 404). "Emotion constitutes the child's psychic life" (p 414). "The more the spring of action is transferred from the emotion itself to the condition that produces it, the better adjusted is the individual" (p 414). And if one is to trouble to mention and define the Oedipus complex for parents, the definition should be a correct one. That given on page 542 is incorrect. While the author's whole point of view, in discussion of the mental and emotional life of the child, is an admirable one and his advice sound, this aspect of the book is less authoritatively treated than are the problems of physical growth and development. The division into age groups has resulted in some degree of repetition.

Die Fermente und ihre Wirkungen. Von Prof. Carl Oppenheimer, Dr. phil. et med. Supplement. Lieferung 2 (Bd 1. Specialer Teil. Hauptteil. VIII). Paper. Price \$6.80. Pp 161-320 with 13 illustrations. The Hague: W. Junk 1935.

The four volumes of the fifth edition of this monumental work were completed in 1929. The new supplement when completed will add two volumes to cover the recent knowledge to the "special part" of the original work, that is, the general field of enzyme research without special reference to methods and technology. The first two issues of the supplement under consideration here cover the esterases and carbohydrases up to heterosides. The same high standards of organization, presentation and completeness are maintained in the new edition that characterized the older editions. In the general discussion on enzyme character are given the views of Willstader to the effect that the enzyme activity may reside in a unit, the "agon," which may or may not be firmly combined with a colloidal complex, the "pheron." The combinations of "agon" and "pheron," called the "simplex," then represent various enzyme combinations with specific activities and various dissociation constants. The discussion on esterases is unusually complete and especially welcome because the great amount of new work on phosphatases is now put together for the first time in an excellent review. In the discussion on the carbohydrases naturally much emphasis is placed on the quantitative and qualitative actions as related to the structure of the substrate. The work continues to be a master reference work for the specialist as well as for the general biologist.

Diseases of Women. By Harry Sturgeon Crossen, M.C., F.A.C.S., Gynecologist to the Barnes Hospital, St. Louis Maternity Hospital and St. Luke's Hospital, and Robert James Crossen, M.D., Instructor in Clinical Gynecology and Obstetrics, Washington University School of Medicine. Eighth edition. Cloth. Price \$10. Pp 999 with 1,058 illustrations. St. Louis: C.V. Mosby Company 1935.

For many years this has been a standard textbook for students because it presents the elements of gynecologic examination and diagnosis in a simple and orderly manner. The present edition, which has been reset as well as revised, has been much improved by the addition of a compact section on gynecologic pathology. This chapter, consisting of 148 pages with 184 illustrations, furnishes the student with an excellent outline of all important infectious and neoplastic diseases of the female genitalia from the pathologist's point of view. The new volume is instructively and profusely illustrated and, in spite of the fact that many of the original photomicrographs have not reproduced well, gives the student an adequate idea of the clinical and histologic appearance of most gynecologic lesions. Newer concepts of the role of hormones in gynecologic physiology, pathology and therapy have been presented with proper conservatism. Since few debatable points have been considered,

the reader may be assured of the soundness and maturity of opinions expressed. The writing is clear and makes fairly smooth reading. There are few repetitions. The publishers as might be expected, have done excellent work. Adverse criticism of a work of such venerable worth is unnecessary. The splendid earlier editions (the first was copyrighted in 1907) have been frequently and faithfully revised. However the plan of the work remains the same. The emphasis is on morphology and pathology rather than on physiology. The style is that of anatomy books, admirable for the beginner but a little tedious for the graduate. There is lack of emphasis on common diseases, and lack of detailed information on uncommon diseases. The general practitioner searching for details of treatment will be disappointed, as will the gynecologist requiring opinions on technical problems such as presacral sympathectomy and radium dosages. Some of the older chapters are verbose, and the newer ones sketchy. Space has been saved by omitting references. Little use is made of the valuable gynecologic statistics that have been accumulated in the last twenty years. One cannot but regret that authors with such experience and knowledge have not produced an entirely new book presenting the same material in a more modern manner. Nevertheless, medical students and those who have used previous editions will find the new volume of great value.

Mikroskopische Methoden in der Mikrochemie. Von Dr. phil. et med. Ludwig Kofler, o. o. Professor und Vorstand des pharmakognostischen Instituts der Universität Innsbruck und Dr. phil. et med. Adelheid Kofler, Unter-Mitarbeiter von Dr. phil. Adolf Mayrhofer, o. o. Professor für Pharmakognosie an der Universität Wien. Monographien aus dem Gesamtgebiete der Mikrochemie. Paper. Price 9 marks. Pp. 134 with 87 illustrations. Vienna & Leipzig: Emil Halm & Co. 1935.

The isolation in recent years, of minute amounts of substances of profound biologic importance has created a need for various types of microchemical methods. The present monograph, one of a series of monographs on microchemical methods describes several such methods performed with the aid of the microscope. The first section, by Dr. Ludwig Kofler describes a reliable method for determining the melting point of less than a millionth of a gram of material. The second section by the same author, deals with microsublimation and describes the preparation of crystals suitable for determinations of melting points and optical properties by subliming minute amounts of material on a microscopic slide. In both sections the author stresses the fact that these microscopic methods yield information which the macro methods are incapable of giving. In a third section Dr. Adelheid Kofler discusses some optical properties of crystals and describes some simple measurements of crystals, using both ordinary and polarized light. These measurements are of great value in the identification of compounds and may be carried out by workers unfamiliar with the highly specialized technique of crystal measurement. There is also an appendix by Dr. Adolf Mayrhofer, on the use of various dispersion mediums in determinations of refractive indexes of crystals. This little monograph will be found interesting and useful not only by those workers who wish to extend their microchemical technique but also by those readers who are seeking a simple discussion of the optical properties of crystals.

Prescription Writing and Formulary. The Art of Prescribing. By Charles Solomon, M.D., Assistant Clinical Professor of Medicine, Long Island College of Medicine. With a foreword by Lewellys F. Barker, M.D. Cloth. Price \$4. Pp. 351 with 32 illustrations. Philadelphia: London: C. B. Lippincott Company. 1935.

The knowledge and skill requisite to prescription writing is an important part of any physician's preparation for the practice of medicine. Individualization of treatment can be practiced only by those familiar with it. There will always be a field for books which add to the clarity of this subject. The author of this book has prepared a treatise that should fulfill the needs of many practicing physicians. The book is simple and written in a well organized and lucid manner. The data are in accord with accepted medical practice and therapeutics. The author stresses the most fundamental aspects of both the science and the art of prescribing. The book is unusually complete for its size and bears the mark of careful editing. Much useless material ordinarily found in books of this type has been omitted and only pertinent scientific and practical facts have been included. The formulary is refreshing in its simplicity.

avoidance of polypharmacy, and preference of official (U.S.P. and N.F.) preparations. When, in the few cases, unofficial preparations are cited, only those accepted by the Council on Pharmacy and Chemistry are given. The medical student and young practitioner of medicine will particularly welcome this book, but any one charged with the responsibility of writing an intelligent prescription can glean much from reading it.

Destiny and Disease in Mental Disorders with Special Reference to the Schizophrenic Psychoses. By C. Macfie Campbell, Professor of Psychiatry, Harvard University. Cloth. Price \$2. Pp. 207. New York: W. W. Norton & Company, Inc. 1935.

Professor Campbell has for long been a brilliant figure in American psychiatry. His clinical acumen and sound conservatism have made him a stanch figure in this country in the field of mental disorders. The present volume incorporates the Thomas W. Salmon memorial lectures and they reflect the best modern psychologic approach in the field of psychiatry. The book divides itself into two portions, one in which the theoretical trends are adequately discussed and in the other of which general trends are illustrated by specific case abstracts. Both sections are written in a style that makes them available for reading by the lay person as well as the interested physician. The general trend of the volume can best be demonstrated by quoting the following passage verbatim:

The study of these serious cases is the study of the tragedy called life and each individual case has its own unique character. No general formula can do full justice to the particular circumstances of the individual case. General formulae are dignified and diagnostic terms give comfort but they are verbal symbols which are apt to do violence to the complexity of the facts. Out of respect for the facts we may be shy of certain diagnostic terms even though we thereby deprive ourselves of a pleasing resting place. Whoever fails to use the familiar verbal symbol may be accused of diagnostic nihilism or of lack of pious recognition of the labors of his predecessors who with unremitting toil constructed their orderly schemata. One may seem to be a disturber of the peace if one rejects familiar diagnostic terms and if one insists that more important than the formal diagnosis of the case is its formulation in terms of the familiar forces of human life based on the painstaking dynamic analysis of the patient and his relation to the environment. With such an outlook the neglect of conventional diagnostic terms may lead to some complaint from our professional colleagues but our patients at least will not be able to reproach us with having failed to do our best to understand the travail of their spirit, their needs and their goals and to bring what ever relief is available to strengthen their bodies, reestablish their personal equilibrium, restore them to their place in the social group.

It is this point of view that makes Campbell's work so worthwhile and his relation with younger psychiatrists of such great importance for the future of this very dark field.

The Pathogenic Aerobic Organisms of the Actinomycetes Group. By Dagny Erikson. Medical Research Council Special Report Series No. 93. Paper. Price 1s. Pp. 61 with 11 illustrations. London: His Majesty's Stationery Office. 1935.

This little monograph is the result of a study of a collection of micro organisms belonging to the Actinomycetes, Streptothrix or Nocardia group obtained from the National Collection of Type Cultures maintained by the Medical Research Council at the Lister Institute. Miss Erikson has made a systematic study of these micro organisms and has attempted to classify them. Twenty-five species, including fifteen that appear to be entirely new, are identified and described. Eleven plates aid in the description of the morphologic features. This work will be of particular interest to bacteriologists and pathologists who are concerned with the relationships of this group of organisms.

Fundamentals of Biochemistry in Relation to Human Physiology. By T. R. Parsons, B.Sc., M.A., Sidney Sussex College, Cambridge. Fifth edition. Cloth. Price \$3. Pp. 453 with 26 illustrations. Baltimore: William Wood & Company, Cambridge: W. Heffer & Sons Ltd. 1935.

The new edition of this excellent and well written elementary textbook is as welcome as were its predecessors. The changes from the last edition are not striking. Most of the nineteen chapters are essentially the same as in the previous edition. The new features are (a) the addition of methionine as one of the amino acids, (b) new factors in the oxidation of fats, (c) more material on the sterols and related substances, (d) a revised discussion of the chemistry of muscle activity and (e) brief references to flavins and to carbaminohemoglobin combinations. As in the previous edition, the author again refers to sodium as the buffer in the red corpuscles. Also no reference is made to the various types of vitamin D known to exist.

Fasciae of the Human Body and Their Relations to the Organs They Envelop. By Edward Slinger M.D. Department of Anatomy College of Physicians and Surgeons Columbia University. Cloth Price \$3. Pp 105 with 24 illustrations by Elizabeth B. Cuzzort. Baltimore: Williams & Wilkins Company 1935.

Fifteen of the illustrations show fascial layers as dissected out from parts of cadavers by the author prepared by a special method of his own, the nature of which he does not divulge. These drawings constitute a real contribution to anatomic illustration. In addition, there are two diagrams and seven illustrations of sections through various parts of the body. There is also a brief text covering forty pages of description, which corresponds fairly well with descriptions of fascias in the standard textbooks of anatomy. The nomenclature throughout is in the Latin form. There are a few mistakes in the Latin form, in the English and in the application of anatomic terms, which will doubtless be corrected in later editions. The illustrations are beautifully reproduced and the form of the book is attractive.

Die Seelenstörungen der Bluthruekkranken. Beiträge zur psychiatrischen Alterspathologie und zu einer 'Psychiatrie auf pathophysiologischer Grundlage. Von Dr. E. Krapf. Paper. Price 6 marks. Pp 120. Leipzig and Vienna: Franz Deuticke 1936.

This booklet comprises a thorough study of mental disturbances found in hypertensive disease. The author working on the large material of the clinic of Munich ably presents his subject in the form of a classification of mental diseases well illustrated by numerous case histories. Almost all forms of psychoses are represented. Although a satisfactory explanation for the outbreak of psychoses in hypertensive disease is missing the author stresses the importance of organic cerebral changes, such as cerebral edema, arteriosclerosis and circulatory disturbances. The book may well be recommended to both the psychiatrist and the internist in dealing with this serious complication of hypertensive disease.

What Everyone Should Know About Venereal Diseases. By E. R. Mills. M.D. Paper. Price 25 cents. Pp 24. Kansas City: Kansas. The Author 1932.

This booklet is written by Dr. Mills "to give the public the true facts regarding the various venereal diseases and their complications." It does exactly that in a concise, informative way which tends neither to give moral preachment to the reader nor to reduce him to a state of hysteria. The layman who wants the facts about venereal diseases—the variety of symptoms and their treatment—will get it here without wading through a lot of irrelevant material. Of course the importance of such a pamphlet lies not only in the manner of its presentation but in the possibility of getting it circulated. There are many persons who would like to have the information in just this form but they may never hear of Dr. Mills's booklet. The medical profession would be doing the public a great service by finding and developing new avenues of distribution for such important facts.

Oxygen and Carbon Dioxide Therapy. By Argyll Campbell M.D. D.Sc. Member of Research Staff, National Institute for Medical Research and E. P. Poulton M.A. D.M. F.R.C.P. Physician to Guy's Hospital. Foreword by Sir Leonard Hill F.R.S. Cloth Price \$4.25. Pp 179 with 49 illustrations. New York and London: Oxford University Press 1934.

This is an excellent presentation of the physiologic and pathologic facts on which oxygen therapy is based together with the clinical indications for its use. The book is particularly valuable, as it presents the experimental evidence of the value of oxygen therapy in considerable detail, especially the experiments of Campbell which definitely show, even under normal conditions, an increase in the oxygen tension of the tissues from the inhalation of oxygen. It is a valuable reference book for every one interested in oxygen therapy.

Essentials of Cardiography. By H. B. Russell M.D. M.R.C.P. Medical Officer in Charge of the Cardiographic Departments at St. Thomas's and the Royal Naval Hospital, London. Cloth. Pp 82 with 75 illustrations. London: J. & A. Churchill Ltd. 1936.

This is another short compend on the interpretation of electrocardiograms of which there has recently been a plethora. The assumption is fallacious that there is a short cut to learning the interpretation of the electrocardiogram. However a booklet such as this might serve the student as the author points out,

as a guide for further study. The author is perhaps too ambitious in attempting to cover so much material in so short a space. He presents a number of electrocardiograms and reproductions of orthodiagrams, and he points out the significance of each type. Many of the electrocardiograms, unfortunately, are distorted by extracardiac oscillations. The book is undoubtedly valuable as a brief compend for the medical student trying to review for examination purposes the subjects covered.

The Biochemistry of the Lipids. By Henry B. Bull. Assistant Professor of Biochemistry, University of Minnesota, Minneapolis. Fibriloid. Price \$3.25. Pp 127 with illustrations. Minneapolis: Burgess Publishing Company 1935.

This monograph contains a mass of factual material presented in a not too readable style, with numerous tables and graphs. Much of the material is valuable but frequently other statements are either entirely too brief or the facts are not sufficiently well established to warrant referring to. It would have been far more satisfactory to restrict the monograph to the descriptive chemistry and the synthesis, digestion, metabolism and functions of the lipids than to include brief and worthless descriptions of analytic methods. The text contains many typographic errors.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice Alleged Negligence in Treatment of Wound.—A bottle that the plaintiff was capping broke, June 4 1931, and pieces of glass entered his right hand at or near the base of the thumb. One piece was promptly pulled out, and the plaintiff, while awaiting the arrival of a physician, immersed his hand in water containing "sylvio naphthol." The physician, the defendant in this case, probed the wound but found no foreign substance in it. He examined the thumb and index finger to ascertain whether "tendons or anything" had been cut, and although the plaintiff was not able to move his thumb, the defendant assured him that as long as he could move his index finger there was nothing in the hand and everything was all right. The defendant bandaged the wound temporarily and that night he put in three metal clips and dressed the wound with a salve. He continued in attendance prescribing the application of hot water and of a solution of epsom salt in water and ordering a bottle of liquid for sleeping purposes. He continued to assure the patient and the patient's wife that the wound was "not infectious at all absolutely good" as late as June 10, when the hand had swelled to more than half again its normal size, the swelling extended up the arm to the neck, and the hand was discolored, numb, and stiff.

On June 10 however, another physician was summoned. He found the patient in a septic condition, "muculated him" and ordered applications of steam towels and an electric pad. The discoloration gradually disappeared the swelling diminished the pain decreased and the patient improved generally. About June 22 the second physician procured a roentgenogram of the injured hand. This showed a small piece of glass in the wound and the patient was then referred to a specialist. The specialist found the tendon cut and the nerve badly severed. An operation was performed, the piece of glass was removed and the necessary repairs were made. A second operation was performed later because of the shortening of the tendon. The patient sued the physician who first attended him but apparently he offered no direct medical testimony to show that the defendant did not exercise proper care and skill. The trial court directed a verdict for the defendant and the patient appealed to the Supreme Judicial Court of Massachusetts.

The duty of the physician-defendant to his patient the plaintiff, said the Supreme Judicial Court, was to use the care and skill of the ordinary practitioner in the community in which he practiced. Only in exceptional cases may a jury determine, without the aid of expert medical opinion, whether the conduct of a physician toward his patient violates that duty. Four medical experts agreed that after an injury of the type here

involved, it would be highly probable that the original wound by glass would cause infection. There was no evidence that the probe used by the defendant was not sterile, or, if it was not, that it caused or contributed to the infection. Since there was no medical evidence to show that the infection followed from any cause other than the wound itself, the jury could not infer that it resulted from the use of infected appliances.

The plaintiff insisted, however, that the jury could have found that the defendant knew or should have known of the probability of infection resulting from the wound and that the jury could readily infer that he did not give the plaintiff proper treatment and attention at a time when, from a layman's point of view, the patient was growing worse. But, said the Supreme Judicial Court, the uncontradicted medical testimony was to the effect that the general treatment of the plaintiff by the defendant was in accord with accepted practice. Moreover, the jury could not have determined by the exercise of common knowledge whether it was or was not proper medical practice to go into the wound to mend the severed tendon or nerve during the period of infection, or, more specifically while the physician-defendant was attending the plaintiff and there was medical testimony to the effect that it would have been improper to operate until after the danger of infection had passed.

A consideration of all the testimony, said the court, disclosed no negligent medical treatment by the defendant. The trial court correctly directed a verdict in his favor. The verdict in favor of the physician-defendant was therefore allowed to stand.—*Bouffard v Canby (Mass.)*, 198 N E 233

Accident Insurance Septicemia Following Trauma—The plaintiff sued as beneficiary on a policy of insurance that provided for the payment of certain benefits if her husband's death should result from septic infection of and through a visible wound caused directly and independently of all other causes by violent and accidental means. Judgment was given for the plaintiff. The defendant insurance company appealed to the Supreme Court of Vermont.

It was agreed that the insured had died of septic infection. The evidence, construed most favorably for the plaintiff, was as follows. As the insured was chopping kindling wood, a stick flew up, and it "looked as though it hit him in the face." A clean cloth which the insured held over the junction of his lip and nose became spotted with blood. Four days later there was swelling and pain in the area over which the insured had held the cloth, and on the following day a physician found an abrasion at the junction of the mucous membrane of the nose with the lip, containing a drop or two of pus. The entire face of the insured soon became discolored and swollen. He died of septicemia on the twelfth day after the accident.

Expert testimony was introduced to prove that the infection in this case was of the type that is introduced into the body only through a break in the skin and that it was extremely probable that it had been introduced by and through the abrasion at the nose. The insurer, however, introduced evidence to prove that the infection might have been caused by a boil that the insured had had in his nose eight weeks prior to the accident. The jury was justified, the court thought, in finding from the evidence presented that the impact of the stick had caused an abrasion and that the septic infection was of and through a visible wound as required by the policy as a condition precedent to payment. The question presented, however, said the court, is whether the injury was caused by violent and accidental means.

That the injury was caused by violent means was not disputed. The insurer contended, however, that although the injury might be called accidental, yet the means was not accidental, the chopping of the wood was voluntary and intentional, and there was nothing to show that it was not performed exactly as intended, with no slip or mishap. After an elaborate discussion of cited cases the court concluded that the term 'accidental means' should be interpreted according to the usage of the average man. It should be understood as being employed in its common significance of happening unexpectedly without intention or design. If the insurer intended the terms 'accident' and 'accidental means' to be construed as differing in their meanings, the contract of insurance should give the insured warning of that fact. The meaning of the term "accidental

means," the court recognized, is dependent for its application on the particular facts presented, what might be the unusual unexpected and unforeseen results under some circumstances might not be such under other circumstances. In this case, the flying up of the stick and its impact on the insured's face was plainly unforeseen and unintended and not a probable consequence of his act. It was an accident, and hence the injury was caused by accidental means. Probably, said the court, all accidental happenings can be traced through the sequence of events back to some voluntary act, but that fact does not attach the voluntary quality of the original act to every subsequent occurrence to which it gives rise.

Judgment for the plaintiff was affirmed.—*Griswold v Metropolitan Life Ins Co (Vt.)*, 180 A 649

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1926 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Cold Pressor Test for Measuring Reactibility of Blood Pressure.—Hines and Brown observed that the response in blood pressure to a standard stimulation (ice water at 4 C) is fairly constant for the normal person. The authors submit the conception that essential hypertension affects only subjects who are hyperreactors. A group of healthy subjects in the later decades of life have been found who have hyperreactions and changes in the retinal arterioles which are indicative of essential hypertension but who have normal or subnormal levels of blood pressure. Normal reactions obtain in aged arteriosclerotic persons whose retinal arterioles do not show changes of hypertension. Subjects with hypertension and arteriosclerosis show hyperreactions. The systolic forms of hypertension seen in neurocirculatory asthema with tachycardia, in glomerular nephritis and in hyperthyroidism give responses definitely less than do the preexistent and existent stages of essential hypertension unless the two conditions coexist. The authors believe that the abnormality of essential hypertension is an excessive response in the blood pressure to intrinsic and extrinsic stimulation. This abnormality is a hereditary one which appears early in life and remains during life. When the level of the blood pressure is elevated and clinical degrees of hypertension exist, the reactions then increase with increasing severity of the hypertension. This hyperreactive vasomotor mechanism may be an important factor in the production of arteriolar hypertrophy and in the subsequent development of the organic stages of the disease.

Heart Failure in Hypertension.—To investigate the cause of heart failure in hypertension, Averbuch studied the hearts of forty hypertensive patients who died with symptoms of myocardial insufficiency. As a control group thirty hearts from patients with hypertension who died of cerebral accidents, renal insufficiency or incidental disease were likewise studied. Thirty-four (85 per cent) of the patients in the cardiac group had significant involvement of the coronary artery (sclerosis or thrombosis) whereas only three (10 per cent) of the subjects in the control group had significant disease of the coronary artery. The myocardial changes in both groups reflected

roughly the extent and degree of involvement of the coronary artery. In six (15 per cent) of the forty cardiac cases there was not sufficient organic change in the coronary arteries or myocardium to account for the heart failure. Three of these six patients had marked pulmonary complications. Theories seeking to explain the cause of the heart failure in the remaining three cases are reviewed.

Mammary Cancer and Nature of Sexual Cycle in Mice.—Burns and his associates compared the following characteristics of the sexual cycle in female mice of ten inbred strains which differed greatly in their incidence of mammary cancer: (1) the duration of estrus (period of keratinization in vaginal epithelium) in the individual mice, (2) the average duration of estrus in the various strains, (3) the total number of days of keratinization during a given period in individual mice of each strain and the averages for the various strains, (4) the average number of estrous cycles in each strain, and (5) the normality or regularity of the estrous cycles in the strains and in the individual mice comprising them. The characteristics of the sexual cycle of different strains of mice differ greatly. These differences seem to be constant within a certain range, in a given strain, as indicated by the concordant results of two series of experiments carried out at different times, however, this holds good only with the restriction that the same individual mice were tested in the successive experiments. Although in

certain cases considerable variations exist, the characteristics of the sexual cycle of individual mice on the whole tend to remain constant. There is no noticeable parallelism between any of these features of the sexual cycle and the frequency with which cancer appears in these strains. It may be concluded therefore, that the hereditary tendency to acquire cancer which is characteristic of strains of inbred mice, is not due essentially to the nature of the sexual cycle which distinguishes these strains from each other. Diet exerts some influence on the character of the sexual cycle. In general, the estrous periods were more normal in those experiments in which chow alone was fed than when a mixed diet consisting of chow, corn and oats was given.

The Course and Treatment of Leukemia—Craver devotes his discussion to a report of selected cases illustrating different aspects of the course and treatment of leukemia. One remarkable feature of leukemia is the great variation in duration of its course. It may be a fulminating catastrophe or an extremely prolonged, relatively benign affliction. Occasionally myelocytic leukemia will run a course of ten years or longer, but a long course seems somewhat more common in lymphocytic leukemia. Case reports descriptive of inadequacy of early biopsies for the prediction of the clinical course, borderline cases, lymphocytic leukemia in young patients, leukemic tumors in adults, leukosarcoma and erythroleukemia are given, and treatment by generalized irradiation is discussed. The aspects of the subject brought into question by the cases reported are the great variations in duration and severity of symptoms, suggestions of relationships between certain leukemias and other diseases, such as Hodgkin's disease, lymphosarcoma and erythremia, differentiation from leukemoid states.

*Bilirubin Concentrations in Human Gallbladder N W Elton Reading Pa—p 81

Bilirubin Concentrations in Gallbladder—Elton observed that the bilirubin contents of fifteen selected gallbladders removed surgically and exhibiting minimal pathologic changes (eleven anatomically normal) ranged from 62 to 1000 mg per hundred cubic centimeters. All concentrations below 50 mg per hundred cubic centimeters were found in the four specimens showing definite chronic inflammatory reactions and are not acceptable as satisfactory minimums because of possible dilution in a pathologic gallbladder. The contents of six apparently normal gallbladders obtained at necropsy exhibited bilirubin levels of from 35 to 1,786 mg per hundred cubic centimeters from which a concentration factor of 510 may be computed. Liver bile obtained by surgical choledochostomy in three patients with complete common duct occlusion ranged from 17 to 714 mg per hundred cubic centimeters in fourteen twenty-four hour specimens. The usual bilirubin content of liver bile obtained by duodenal drainage in individuals with no known gallbladder disease is from 8 to 10 mg per hundred cubic centimeters, with a further possible decrease to 2 mg per hundred cubic centimeters after prolonged cholestasis. The great variability in the bilirubin content of liver bile, ranging from 2 to 714 mg per hundred cubic centimeters and due to the increased water output of the liver after prolonged cholestasis in individuals without gallbladder dysfunction and to the inhibition of cholestasis in cholestatic disease and hepatic injury, makes it difficult to select a satisfactory average minimal level in liver bile for comparison with the bilirubin contents of gallbladders. However a concentration factor of 105 may be computed from the fact that liver bile obtained by surgical drainage

contained 17 mg per hundred cubic centimeters and that a normal gallbladder contained 1,786 mg per hundred cubic centimeters. A factor of 125 to 100 may be computed from the observation that liver bile in the absence of cholestatic disease ranges from 8 to 10 mg per hundred cubic centimeters and that it is not unusual for a gallbladder to contain bile of 1,000 mg per hundred cubic centimeters. Since it is possible for a clear alkaline liver bile to have a bilirubin level as low as 2 mg per hundred cubic centimeters, an extreme combined factor for liver and gallbladder jointly might be computed as 893. A most conservative concentration factor, attained without undue fasting, appears to be from 30 to 50.

Influence of Odor on Appetite—Winslow and Herrington used eight young men between 17 and 19 years of age as experimental subjects. They came to the laboratory on four or five mornings each week during the months of February, March and April 1935 and were kept under observation in one of the experimental rooms from 9:30 a m until 12:30 p m. On certain days the subjects were exposed to the odor of heated house dust, while on other days no such odor was present. This odor was selected as an example of one to which exposure is common and which, although the odor is a relatively mild one is often noted as subjectively undesirable.

The investigation shows that the odor given off from heated house dust (even when not consciously perceived) has a clearly demonstrable effect in reducing the appetite for food and hence may be considered as definitely harmful to health. From a general physiologic standpoint the results seem to be of some importance. They furnish the most convincing evidence that has yet been offered (indeed, the only controlled objective evidence that has been offered except for the results of the New York State Commission on Ventilation) of the effect of mild organic odors on human health and comfort.

Repair of Damaged Finger Tendons.—The method of Mayer and Ransohoff for supplying a new sheath in the repair of damaged finger tendons is as follows: Pure celloidin tubes, varying in size and length to correspond with the varying sizes of the digital tendon sheaths, are prepared in advance and sterilized for twenty minutes in a 1:2000 solution of mercuric oxyanide. They are then placed in sterile solution of sodium chloride until ready for implantation. The operation is done in two stages: the first consists in the complete excision of the scar and the implantation of the celloidin tube; the second performed after a lapse of from four to six weeks in the removal of the tube and the implantation of the new tendon. In all but one of the cases, both in experimental animals and in the authors' patients, the celloidin tube healed in aseptically and at the second operation was found enveloped by a smooth glistening tissue, the surface of which microscopically and macroscopically resembled that of a normal sheath. Through this smooth walled channel the grafted tendon could be seen gliding as the patient contracted his muscle much as the normal tendon glides through the digital theca. The normal relationship between tendon and sheath had been restored. The present technique has enabled the authors to immobilize the operated finger for from ten to fourteen days without creating vicious adhesions between the tendon and the new sheath. During this period the grafted tendon has united to the host with sufficient firmness to permit active exercises and electrical stimulation.

Intradermal Test for Pregnancy.—Grushkin bases his test on previous work concerning the nature of homologous proteins producing an allergic reaction by the formation of pseudopods when injected intradermally in positive cases of malignant manifestations. The same principle has been applied in the determination of pregnancy by the use of placental tissue as an antigen, which, when introduced intradermally, causes pseudopod formation at the site of injection in pregnant women, but no pseudopods appear when pregnancy does not exist. One-tenth cubic centimeter of the antigen is injected intradermally with a 27 gage needle and a 1 cc tuberculin syringe. The injection should not be forced. In positive cases a slight area of inflammation with pseudopod formation appears within ten minutes. In negative cases no such reaction takes place. It is advisable to use a control of physiologic solution of sodium chloride with each test. The control must always be negative, showing no inflammation and no pseudopods. The bleb after the injection must be perfectly round and have the appearance of orange peel due to the hair follicles, in which case one is sure that the test was done intradermally. For the preparation of the antigen, placentas are obtained as soon as possible following delivery. They are washed, cleaned and freed from blood, ground into pulp and placed in acetone three times their volume, for twenty-four hours. The acetone is poured off, the tissue allowed to dry and the acetone evaporated. It is then extracted with a tenth normal sodium hydroxide solution for twenty-four hours and neutralized with a solution of hydrochloric acid and a buffer solution made of 0.05 normal hydrochloric acid and 2.27 Gm. of potassium dihydrogen phosphate per liter. The antigen is brought to a pH of 6.9, and 6 drops (0.4 cc.) of a mixture of two parts of glycerin to one of tricresol for every 10 cc. of the extract is added as a preservative. It is then placed in pyrex containers and is ready for use. This test should not be done during menstruation owing to the decidual involvement of that process which will respond to the homologous protein of the placental extract, giving positive reactions. It should not be performed in endocrine disturbances or on hypersensitive skins, which might respond to anything.

Low Reserve Kidney.—As the result of a five year follow-up study of a series of toxemic patients originally diagnosed as having "low reserve kidney," Peckham and Stout find it necessary to alter the concept of this condition as proposed by Stander and Peckham in 1926. It is their opinion that the condition is limited to primiparas and that it manifests itself, usually not before the last month of gestation, by the presence of a moderate degree of hypertension and a small amount of albumin in the urine. Ordinarily it clears up rapidly in the early puerperium and does not recur with subsequent pregnancies. Clinically the course is mild and does not resemble true preeclampsia.

Reaction of Connective Tissues to Lipids.—Tompkins carried out five groups of experiments on guinea-pigs. 1. The subcutaneous tissues were studied at various intervals of time following single injections of a variety of unrelated foreign bodies (phosphorus in olive oil, olive oil liquid petrolatum,

poppy-seed oil, and the like) 2 Subcutaneous injections of lecithin prepared from egg yolk were given 3 Injections of lecithin and liquid petrolatum were given singly or mixed 4 Also in rabbits, lipids prepared from brains were injected subcutaneously 5 Studies were made of the peritoneal reactions in rabbits and guinea-pigs following repeated injections of some of the substances used in the first three experiments The reaction of the connective tissues to many unrelated foreign bodies including tubercle bacilli, is presented by the following sequence of events 1 An early influx of polymorphonuclear cells, which subsides in a few days 2 Appearance of monocytes about three days after the injections these quickly develop to great size and activity 3 Appearance of clasmatocytes about five days after the injections 4 Appearance of epithelioid cells and of transitional forms between them and both monocytes and clasmatocytes about eight days after the injections 5 Appearance of giant cells of both foreign body and epithelioid types about ten days after the injections Injection of the connective tissues with lipids prepared from egg yolk and from brains causes focal increases of macrophages similar to those caused by the injection of other foreign bodies In contrast to the degenerative changes produced in the macrophages in the latter case, however the cells become hyperactive physiologically in the areas injected with the lipids and show no evidences of degeneration into epithelioid and giant cells These lipids are quickly removed from the areas of injection without residual modification of the tissues

Gonorrhea as a Mask for Early Syphilis—Kemp and Shaw studied 1,000 cases of acute gonorrhea to determine its role in masking or altering the presence of primary syphilis They found that 155 (15.5 per cent) of the group had syphilis, of whom forty-one (26.4 per cent) had early syphilis contracted simultaneously with gonorrhea In every instance of primary syphilis the clinical diagnosis was made by detection of the chancre and in not a single instance did it depend only on the development of a positive blood Wassermann reaction Of nineteen patients with secondary syphilis, only three were unaware of the eruption Among the forty-nine patients with late syphilis who were unaware that they were infected, only thirteen (26.5 per cent) gave a history of a previous attack of gonorrhea Of the sixty-one patients in whom syphilis had been diagnosed before admission, only thirteen (21.3 per cent) had received adequate treatment Thirty-four of the 1,000 patients had genital lesions that were proved by repeated dark-field examinations and blood Wassermann follow up to be non-syphilitic There were no instances of 'symptomless infection' with syphilis occurring simultaneously with gonorrhea

Infectious Intertrigo—Howles shows the protein nature of the infectious intertrigos in his survey of 2,086 clinically and microscopically positive cases Cocci, yeast and fungi were all proved to be etiologic factors either singly or in combina-

tion Of the 600 cultures studied mycologically, 10 per cent were positive for pathogenic fungi To enable a fair evaluation of the therapeutic measures employed, various remedies (keratolytic agents, mechanical abrasives, chemical abrasive agents, fungistatic and germicidal agents and physical agents) were tested for adequate periods of time under controlled conditions The rational therapy of infectious intertrigo cannot be found in one set remedy Each stage of these eruptions must be managed differently, therefore the discovery of a panacea is improbable Conservative treatment in the acute stages is essential Hygienic and prophylactic measures seem to be the ultimate answer to the question

Congenital and Familial Clubbing of Fingers—Witherspoon points out that clubbing of the fingers and toes has been recognized as a clinical manifestation of intrathoracic disease from the earliest times Hippocrates described the condition as occurring with advanced phthisis and empyema and emphasized the importance of the changes as diagnostic of purulent pleural effusion Many subsequent authors have described clubbing of the fingers associated with chronic disease of the heart or lungs, but it is still rare in medical literature to find the condition mentioned as being of primary origin The author considers his case of simple clubbing of the hands and toes apparently of primary origin He states that it is familial possibly hereditary, is congenital as far as can be determined from the history, and supposedly is the first instance of simple familial and congenital clubbing of the fingers and toes in a Negro to be described in medical literature

Effect of Ergotamine Tartrate on Cerebrospinal Fluid Pressure—Pool and his co-workers thought that a study of the physiologic effects of ergotamine on patients during a migraine headache might uncover the cause of the relief and hence suggest the cause of the migraine With this thought in mind they have observed the effects of ergotamine tartrate on the pressure of the cerebrospinal fluid and of the arterial blood, on the rate of the heart and on the symptoms of patients who were suffering from an attack of migraine As a control, similar observations were made on a group of patients not subject to migraine It was found that the average initial spinal fluid pressure during headache was 113 mm, a figure 14 mm lower than the average pressure for the control group Following the injection of ergotamine, there was in both groups a prompt fall in pulse rate and a rise in systolic and diastolic blood pressure and in spinal fluid pressure After injection of

ergotamine in the patients having headache, the average rise in the level of spinal fluid pressure was 13 mm, in the controls the level rose 31 mm. The relief from headache which twelve of the fifteen patients with migraine experienced could not be directly or entirely explained by the observed changes in cerebrospinal fluid pressure or in the circulation. The observations do not lend support to the theory that in migraine headache there is a generalized spasm of cerebral vessels or an abnormality of intracranial pressure. It is possible that ergotamine acts directly as a sedative on the sensory nerves which supply intracranial tissues, particularly those nerves which accompany arteries or supply the dura, or that it acts directly on autonomic nuclei in the hypothalamus. This explanation does not however take into account the fact that ergotamine relieves not only the headache but also other symptoms, such as scotoma, hemianopia, paralysis and malaise.

Rheumatic Cardiac Disease—Werner studied 100 consecutive ward cases of rheumatic cardiac disease in which there was heart failure, seventy-five cases of the same condition with necropsy and fifty cases of syphilitic cardiac disease included for comparative purposes. Signs of active rheumatic fever have been demonstrated in 45 per cent of the clinical cases of rheumatic cardiac disease. Activity has been suspected in an additional 21 per cent. In the pathologic material active lesions have been found in 66 per cent of the cases of rheumatic cardiac disease. An exertional or mechanical factor associated with cardiac insufficiency was definite in only 8 per cent of the cases of rheumatic cardiac disease and 7 per cent of the cases of syphilitic cardiac disease. There was no demonstrable factor in the remaining 26 per cent and 48 per cent of the cases of rheumatic and syphilitic cardiac disease, respectively. Infection of the respiratory tract is concomitant with the loss of cardiac reserve in 50 per cent of the clinical cases of rheumatic and syphilitic cardiac disease. A seasonal rise in the number of patients with rheumatic fever admitted to the hospital for cardiac insufficiency is indicated corresponding to the known statistics on morbidity for rheumatic fever in New York City. The observation is not demonstrable in the series with syphilitic cardiac disease.

Erythrocyte Fragility in Pneumonia—Needles discusses the fragility of the erythrocytes in pneumonia and describes a modified technic for their determination. It is believed that the use of the test may open new avenues in the investigation of pneumonia, and it is suggested that the test be employed in cases of other infections particularly of the pulmonary type. A difference in climate and race may cause some difference in results. In pneumonia, depending on the severity of the illness and on its toxicity or the amount of lung tissue involved the resistance of the red blood cells to hemolysis becomes greater. When the disease is mild, this may amount to as little as from 0.02 to 0.04 per cent, while when it is severe it may be as great as 0.14 per cent. In fatal cases the resistance of the erythrocytes is very great becoming progressively more marked as the disease advances. There is a possible use for such an examination as an aid to prognosis. Mild pneumonia causes only slight changes in fragility. Therefore it may be assumed that as long as the erythrocyte resistance remains above 0.4 per cent the prognosis is good. However the author has seen patients recover in whom the point of beginning hemolysis had been as low as 0.34 per cent. The crisis in fragility lags from one to three days behind the crisis in fever, and it is not unusual to see low fragility readings from one to three days following the restoration of the normal temperature. The mechanism is not clear. It seems likely that it is a phenomenon intimately related to the amount of lung tissue consolidated and thus connected with the oxygen carbon dioxide equilibrium of the blood. The cases that the author reports occurred in Brazilians and there may be some racial idiosyncrasy. Most of the patients in this region are carriers of chronic malaria, many have syphilis, and almost all have one or more types of intestinal parasites. In nearly all the spleen is enlarged from one to four times. The series of normal patients have shown that the normal limits for erythrocyte fragility in this area are the same as in more northern climates and in the white race, i. e., from 0.36 to 0.44 per cent and would tend to show that the same pathologic reactions would also be present. This is not conclusive.

Etiology of Amyloid Disease—The experiments of Eklund and Reimann show that constant hyperglobulinemia induced by repeated injections of sodium caseinate preceded the development of amyloid disease in each of five rabbits. The observations support the theory that chronic hyperglobulinemia is important in the development of amyloidosis of the secondary type. During long periods of hyperglobulinemia an attempt is made by the cells to remove the excess of globulin from the blood. If the amount is not too great or too persistent, the excess can be disposed of successfully. However, if the cells become overwhelmed or if they cease to function owing to injury or disease, excess amounts are deposited in increasing quantities until the condition is incompatible with life. Furthermore, experimental studies and clinical observations show beyond doubt that the process is reversible. If the conditions responsible for the hyperglobulinemia are removed, provided the amyloidosis is not too extensive, resorption of the substance and recovery may occur. Histologic sections of the kidneys of the rabbits studied showed extensive destruction of glomeruli caused by the deposit of amyloid substance in the tufts. The tubules were generally dilated and plugged with amyloid. In four rabbits it appeared that the depletion of the albumin content of the blood was caused by the escape of abnormally large amounts of albumin through the damaged kidneys. In the other rabbit a diminution in the amount of blood albumin was noted nine months before marked albuminuria occurred. In this rabbit in contrast with the others there was extensive infiltration of the liver and spleen, which may have been partly responsible for the diminution in the amount of blood protein. The symptoms, signs, laboratory data and pathologic changes in the kidneys of rabbits in the terminal stage of amyloidosis were typical of those noted during renal amyloidosis and uremia in man in regard to albuminuria, normal blood pressure, normal eye grounds, retention of nonprotein nitrogen, positive congo red test and lowering of the blood protein level, with marked loss of albumin and relative or absolute increase in the amount of globulin. Edema was not noted. Extensive renal amyloidosis developed in each animal, which appeared to be heralded clinically by albuminuria and a drop in the blood protein level. Both renal and hepatic lesions are known to modify the blood protein level. It is misleading, therefore, to attempt to correlate the changes in the blood protein level found in advanced amyloidosis with the etiology of the disease. The conditions are different during the incipient period of the disease. The amount of blood protein, especially that of the globulin was markedly above normal. In the late stage, when evidence of renal disease appeared, the total protein content was reduced below the normal level, because of the marked diminution of the albumin content.

Myasthenia Gravis—When performing a necropsy in a case of myasthenia gravis shortly after a similar examination had been made in a case of dermatomyositis, Butt observed that microscopic study of the muscles in the two cases revealed certain resemblances. The collections of lymphocytes in the muscles in both cases suggested a chronic infection. The inference was that the underlying cause of myasthenia gravis was a type of infection that became localized in the muscles in a manner similar to the localization of rheumatism in joints and also that, since the lesions in myasthenia gravis, scleroderma and dermatomyositis often present similar pictures, they might all be related to a common type of infection with different local-

izing properties. This observation led to the study of the pathologic changes in seven cases of myasthenia gravis in which necropsy had been performed. In muscles from the bodies of seven patients who died of causes other than myasthenia gravis, no bacteria could be observed but gram-positive bacteria resembling streptococci were noted in the seven cases of myasthenia gravis. The possibility of contamination of the tissues by the microtome knife or by fluids used in preparation was excluded. Collections of lymphocytes were observed in all but two of the seven cases of myasthenia gravis. In all the cases there was a form of degeneration in some of the sections of muscle. Thymomas were observed in two cases. The fact that gram-positive organisms were observed in the muscles of the patients who had myasthenia gravis and were not seen in the muscles of a similar number of control subjects suggests that these bacteria may be the origin of the toxin that produces the characteristic fatigability in this disease.

Treatment of Congenital Syphilis—Davidson and Birt state that acetarsone (stovarsol) was introduced at the Winnipeg Children's Hospital in 1932 and that the results obtained since then have been superior to those produced by older methods of treatment. The decided increase in cases cured assures this drug a place in the therapy of congenital syphilis. In addition it offers the following advantages over other forms of treatment: 1. The oral method is much superior to the intravenous or the intramuscular route in children. 2. Syphilis can be cured only by regular treatment. In the preacetarsone series there were many at the clinic irregular in attendance. Since the introduction of acetarsone and the cessation of painful treatments there has been no difficulty in having the children attend the clinic regularly. 3. There have been fewer toxic effects in this series than are usually found with arsphenamine and neoarsphenamine. Those that have been produced were readily controlled by dosage. 4. Treatment is much cheaper than by other methods and there is no additional equipment necessary for administration. While the results obtained in their series of thirty-seven cases have been highly satisfactory (more than twice as many cures were obtained in one-third the time required for preacetarsone treatment) it seems to the authors that better results might be obtained by using a graduated dosage of acetarsone. It is their intention to treat a series of cases using the method advocated by Bratuschi-Marrain.

Histidine Monohydrochloride Therapy of Gastric Ulcer—Volini and McLaughlin give the results of seventy-three patients treated by parenteral histidine monohydrochloride, observed over a period of six months. After a six months check-up, 79 per cent of the cases were clinically improved and 21 per cent were considered failures. The percentage of favorable responses varied inversely with the duration of the symptoms. It is very difficult to evaluate the mode of action whereby histidine produces the beneficial result. Weiss and Aron expressed the opinion that histidine promotes, restores and maintains the epithelial integrity of the gastric and duodenal mucosa. The absence of histidine, an essential amino acid not synthesized in the human body, thus produces a metabolic defect, which is restored by parenteral injection in this treatment. The possibility of a different mode of action has been investigated by the authors in studies on ulcer production and prevention which are in course of publication. They produced gastric ulcers in rats by repeated injections of histamine dihydrochloride. They also demonstrated ulcer formation in rats by the use of repeated histamine enemas. These experimental ulcers did not occur when the animals were protected by previous injections of histidine monohydrochloride. Their observations suggest, first, a working hypothesis for ulcer production that is by repeated histamine stimulation, peptic ulcers are produced. Further scientific investigation is being made. Secondly, another working hypothesis is permissible, that histidine stimulates the production of histaminase, which inactivates histamine. Gastrin (gastric secretin) action is inhibited, thus reducing gastric juice acidity, gastric secretion and possibly peptic activity. This could explain the change in physical character in the gastric secretion. The diminution in gastric motility could likewise be attributed to this action.

Leukopenic Index in Intractable Asthma—Zeller performed 106 leukopenic index determinations on twelve patients in whom the usual diagnostic procedures failed to reveal sufficient observations to effect relief of symptoms. Of the fifty-four proved clinically positive instances, thirty-seven showed negative skin tests with a decrease in the white cell counts of more than 1,000 cells. This represents 34.91 per cent of the total number of cases tested and 68.52 per cent of the clinically positive cases. An increase in leukocytes with proved positive clinical response but negative skin tests was presented in twelve foods (11.32 per cent) of the total number and 22.22 per cent of the clinically positive instances. In three clinically positive foods the leukopenic response corresponded with the positive skin test while in two clinically positive foods an increase of

leukocytes with positive skin tests was noted. Of the thirty-nine clinically negative instances, twenty-three (21.70 per cent) of the total number (106) tested showed a digestion leukocytosis associated with negative skin test. Six clinically negative foods with positive skin tests also showed a leukocytosis, while one showed a leukopenia. Nine clinically negative foods showed a leukopenia with negative skin tests. Five of the twelve cases of asthma eventuated in good results clinically. Three had responded fairly well to the usual allergic measures, but after utilizing information gained by the leukopenic index determinations improved to the extent of being classified under good results. The remaining two cases presented no improvement prior to leukopenic index determinations. Four cases in which fair results were obtained had shown no clinical improvement until food eliminations based on leukocyte counts were made. No improvement was obtained in three cases. One of these failed to show a single food producing blood counts toward the positive phase. The remaining two failed to respond clinically even after eliminating foods with leukocytic indexes in the negative phase.

Treatment of Hemorrhage with Theelin in Oil.—De Silva used theelin in oil in the treatment of hemophilic and nonhemophilic hemorrhage. With the intramuscular use of one ampule, 1,000 international units per cubic centimeter of theelin in oil every two to three hours, great improvement if not complete cessation, was apparent after the injection of from three to four ampules. The use of theelin has proved of exceptional value in the author's hands but must be given as often as every two hours in one ampule doses unless in extreme conditions when he advises two ampules for the first dose. Several patients have complained of severe stinging at the site of injection, which he relieved by drawing the theelin into the syringe and then 4 to 5 mm. of a 1 to 2 per cent solution of procaine hydrochloride, so that on injecting, the amount of procaine was injected first and after four or five seconds the rest of the syringe, with absolutely no pain to the patient who even asked if the hypodermic had been given. Several cases are cited. The author is of the opinion that the ovaries in the female are the restrainer of the hemophilic conditions but that their destruction or removal may allow hemophilia to occur.

Study of Pneumococcus Toxins.—Coca demonstrated a toxin in filtrates of pneumococcus cultures the injection of which in young children caused a rise in temperature, which reached 105 F in the more susceptible. All of thirty-four children less than 3 years of age, excepting two who previously suffered from either bronchopneumonia or a severe bronchitis were found susceptible to the type I toxin. All of thirty-one persons suffering from or convalescent from pneumococcal pneumonia were found immune to the type I toxin (skin test). The toxin seems to be type specific. It is not the type-specific polysaccharide. Cultures grown in the absence of artificially supplied carbon dioxide have been found to contain toxin which, however, seemed not to be capable of stimulating antitoxin production in human beings. Two injections in children were followed in the majority of instances by prompt antitoxin production (one or two weeks). Serum from two pneumonia convalescents neutralized the pneumococcus type I toxin.

Behavior of Eosinophils in Rheumatic Fever.—Friedman and Holtz present seven case histories illustrating four features of the behavior of the eosinophils during the course of rheumatic infection. These are (1) the disappearance of the eosinophils from the peripheral circulation during accessions of acute polyarthritides and carditis, (2) the reappearance of the eosinophils and eosinophilia during the early stages of recovery, (3) persistent eosinophilia in cases of continued activity and (4) transient hypo eosinophilia or a eosinophilia during minor exacerbations in cases of chronic rheumatic heart disease. The behavior of the eosinophilic polymorphonuclear leukocytes in rheumatic fever is similar in all respects to that seen in other infections. In so-called chronic rheumatic heart disease the presence and absence of the eosinophils and the occurrence of eosinophilia have the same significance as in other infections. The concept of rheumatic heart disease as a chronic infection with frequent acute exacerbations of variable degree offers the

key to an understanding of the apparent complexity of the eosinophilic behavior. Thus repeated and continuous absence of the eosinophils from the blood over a period of time was always found to be associated with other evidences of a severe and active infection. In the majority of cases showing continuous aneosinophilia or hypo-eosinophilia of this type the patient was ill enough to be confined to bed. Conversely, when the eosinophils were continuously present in normal or increased numbers, the infection was always subsiding. Eosinophilia indicates convalescence which in rheumatic fever is admittedly very often a protracted process. Occasional aneosinophilia occurring in patients who usually present normal or high counts undoubtedly indicates miniature exacerbations of activity which give rise to little or no clinical disturbance. The eosinophil behavior in rheumatic fever affords another point of identity and the analogy constitutes further evidence in favor of the allergic hypothesis. Continued observation of the behavior of the eosinophils, over long periods of time in the less acute cases, is a reliable index of activity of rheumatic infection and is valuable as a basis, in some cases, for immediate prognosis and clinical management.

Liver-Kidney Syndrome—Their observations in two cases illustrative of the liver-kidney syndrome suggest to Helwig and Schutz the idea that the pathogenesis of the syndrome depends primarily more on the development of some specific type of intracellular hepatic damage than on the degree of actual morphologic cellular damage to which ordinary cell injury may extend. When they consider the wide variety of liver lesions and the more constant sequence of clinical events in which the renal picture assumes the most prominence as the syndrome progresses, it appears more and more convincing that some toxin is the causative factor. This toxin may have been produced as the result of a perversion of function of damaged liver cells or by a lack of some physiologic detoxifying function of the liver parenchyma that permitted the production or the accumulation of a substance highly toxic to renal function. A hemorrhagic diathesis is also not a rare complication in certain cases of renal disease when no accompanying liver lesion is present. At present, however, the true etiology of such bleeding is not completely understood. Experimentally uniform results could not be obtained when an attempt was made to reproduce the liver-kidney syndrome in animals.

Thoracic Duct Lymph Pressure in Concretio Cordis—Blalock and Burwell produced Pick's disease in two dogs by the introduction of aleuronat into the pericardial cavity. This resulted first in the formation of fluid in the pericardial cavity and later in the fusion of the pericardium and epicardium. The venous pressure rose and fluid accumulated in the peritoneal cavity. Three weeks following the introduction of aleuronat into the first dog, the pressure in the external jugular vein was 120 mm of water and that in the femoral vein 140 mm. Under morphine narcosis the cerebrospinal fluid pressure was found to be 240 mm of water. Under ether anesthesia the thoracic duct which was markedly dilated was exposed in the neck. Blood was present in the duct for a distance of approximately 1 cm peripheral to its entrance into the vein. The pressure in the duct was found to be 150 mm of water, while that in the subclavian vein was 165 mm. The animal was killed and a typical instance of concretio cordis was demonstrated. In the second experiment the animal appeared ill seventeen days following the introduction of aleuronat. The pressure in the external jugular vein was 155 mm of water and that in the femoral vein 175 mm. The cerebrospinal fluid pressure was 200 mm. Under ether anesthesia a markedly dilated thoracic duct was exposed. A small amount of blood could be seen during expiration in the duct at its entrance into the vein. The pressure in the thoracic duct was found to be 200 mm of water and that in the subclavian vein 175 mm. Following the removal of the needle from the duct a pulsating stream of lymph shot out through the hole of the needle during each expiration. Several hundred cubic centimeters of lymph escaped during the thirty minutes that the duct was exposed. The incision was closed and the animal died two days later. There were 1100 cc of blood tinged fluid in the pleural cavities and 90 cc of thin yellowish fluid in the peritoneal cavity. The pericardium and epicardium were fused and thickened. There was an exudate covering the liver

Sensitive Complement Fixation Test for Gonorrhea—Koopman and Falker devised a complement fixation test for gonorrhea that requires a readjustment of the quantities of reagents used and a new interpretation of readings. In a proper gonorrhea fixation test it is imperative that the readings be made at the point where the concentration of complement approaches its threshold value when the concentration of complement is reduced, the test cannot be completed in the usual manner because the control tubes will be anticomplementary and the reaction tubes will not show definite positive or negative reactions. A properly planned titration demonstrates how these difficulties may be overcome. Therefore when the first requisite of gonorrhea fixation tests is fulfilled, i. e., the use of reduced concentration of complement, to get clearer control tubes and clear cut negative reactions, the cell suspensions must be lighter than those used in present work. Furthermore, as the density of the suspensions is decreased, hemolysis disappears in the positive reaction tubes and definite positive reactions are at last attained. The authors have found that highly satisfactory results are obtained when one fifth of the reacting complement fixation solution is made up of sensitized cells. The sensitized cell suspension consists of one part of 5 per cent cells and one and one-half parts of hemolysin of the proper titer. The standard that determines their readings is that complement fixation should be judged by the difference between the amount of complement absorbed nonspecifically in the control tube and the amounts fixed both nonspecifically and specifically in the reaction tubes. An essential difference between the proposed test and the classic test is that they do not attempt a quantitative estimation of complement fixation by varying the amount of serum but by changing the concentration of the complement in the hemolytic system and by estimating the amount of fixation by the threshold value of the complement left over. In this new test, advantage is taken of the fact that in hemolytic systems complement acts according to its concentration rather than its absolute quantity. That quantity of complement to be used in the tests is the amount which causes almost complete hemolysis. The proper tube will have a trace of cloudiness caused by cells that have not been hemolyzed. The complement is then diluted so that 0.1 cc contains the amount indicated by the titration. It is essential that the amount of antigen used is an excess. Additional antigen should not increase the amount of fixation of the positive specimens. For ease of manipulation following the first incubation, the saline and sensitized cell suspension should be mixed together and added by a single pipetting, and the specimens reincubated. This also makes for increased accuracy. In a minus reaction, the first reaction tube is as much hemolyzed as the control. In a plus reaction, the first reaction tube colorimetrically shows definite fixation against the control. The second reaction tube approaches complete hemolysis. In a two plus reaction, the first reaction tube has only a faint trace of hemolysis or is completely fixed. The second reaction tube has much hemolysis. In a three plus reaction, the first reaction tube is completely fixed. The second reaction tube has a faint trace of hemolysis or is completely fixed. The third reaction tube has definite hemolysis. In a four plus reaction, all the reaction tubes are completely fixed.

Use of Acetylsalicylic Acid and Magnesium Oxide in Rheumatic Infection—Kaiser attended two groups of rheumatic children (seventy-five in each) with similar manifestations over a period of from six to twelve months. The treated group

received daily from 10 to 15 grains (0.65 to 1 Gm) of acetylsalicylic acid with magnesium oxide. This group showed a decided improvement over the untreated group in the children who had rheumatic pains alone. The treated children with chorea likewise fared better than did the control group not so treated. No measurable benefit could be noted in the treated group who showed evidence of rheumatic carditis alone. The vague or milder manifestations of rheumatic infection were relieved in more of the treated children than in the control children. There were fewer recurrent attacks of major rheumatic manifestations in the treated group than in the control group. No untoward or unpleasant reactions were observed in any of the treated cases. It would seem that acetylsalicylic acid with the addition of magnesium oxide is preferable to other antirheumatic drugs when used over a long period of time.

Adolescent Development in Girls—Pryor made a serial study of the adolescent growth spurt in 100 girls from 9.5 to 14 years of age. Examinations extending over four years, at half-year intervals, demonstrated a period of rapid growth during the six months immediately preceding the onset of catamenia. Gain in height preceded gain in weight and was evenly distributed over a period of eighteen months. Pubescent girls averaged a height increase of 10.64 cm in eighteen months, compared to 9.38 cm for nonpubescent girls. The rate of height gain for pubescent girls during the last six months before the appearance of menses was 26 per cent faster than for nonpubescent girls. Gain in weight was specifically stimulated by approaching menses. Pubescent girls gained weight 55 per cent faster during the six months just preceding catamenia than they did during the preceding year. Girls of broad body build menstruated earlier than girls of slender build. Pubescent girls were consistently taller, heavier and broader than nonpubescent girls of similar ages in a series of 422 cases. A predominant pattern of development of pubic and axillary hair accompanied the onset of catamenia regardless of chronological age. A certain degree of enlargement of the thyroid appeared destined to accompany the first appearance of menses. A fairly constant stage of development of the breast was seen regularly at the same time. Interrelationships among certain secondary sex characteristics suggest themselves as criteria of a physiologic age which is much more constant than chronological age for predicting the onset of catamenia.

Malarial Therapy—Hutchings deals with the report of 182 male dementia paralytica patients who were admitted to the hospital in a routine way and who were thought to be in a suitable condition for malarial therapy. Many of the patients received treatment with arsenicals as well and these are considered. Of the 182 patients sixty-six were much improved by

treatment and were discharged. There were fifty-four who improved under treatment, of this number, twenty-five returned home able to do some work, ten who were considered to be improved were not discharged and subsequently died in the hospital, and nineteen remain in the hospital today. Of the remaining sixty-two who did not show any satisfactory response to treatment, twenty-three are still in the hospital and thirty-nine are dead.

- *Correlation Between Shape of Female Pelvis and Clinical Course of Labor A V Pettit L H Garland R D Dunn and P Shumaker San Francisco—p 1
- \ Ray Examination of the Obstetric Patient C R Johnson Los Angeles—p 21
- *Is the So Called Safe Period Trustworthy? L A Emge San Francisco—p 28

Labor and Shape of the Female Pelvis—Pettit and his collaborators found that in their 100 unselected primigravidas the relative incidence of the various types of pelvis as determined roentgenographically compares fairly closely with that of Caldwell and Moloy in their studies of skeletal material. The incidence of these types was found to be gynecoid group, 51 per cent, android group, 21 per cent anthropoid group, 18 per cent, platypelloid group, 5 per cent asymmetrical pelvis, 5 per cent. In the 100 pelvis approximately 65 per cent constituted "pure" types and 35 per cent "mixed" types. The obstetric significance of the various types of pelvis appears to be as follows: 1 The necessity for operative intervention in the gynecoid types is low. 2 The necessity for intervention in the android, anthropoid and platypelloid groups is increased especially in the "pure" types of these pelvis, being as high as 40 per cent in the android types. 3 A narrow subpubic angle is the most unfavorable single anatomic feature in producing difficult labors. It is not sufficient to classify pelvis on shape alone, the type of the pelvis, the size of the inlet and the shape of the subpubic angle should be considered.

The Safe Period—Emge believes that fertilization must follow in close sequence to cohabitation, assuming that only one egg is produced in each human cycle. The proverbial unreliability of the so-called regular cycles of menstruation is still the greatest stumbling block in predicting periods of conception. More and more evidence is being introduced that unexpected irregularities in menstruation can occur at any time and in any cycle. Hence, one must doubt the infallibility of the Ogino-Knaus theory, even if applied only in the strictest sense of limiting it to known cycles of minor variabilities. The formidable proof offered by Miller and by Latz puts considerable weight behind the claims made for the Ogino-Knaus theory. Nevertheless is it not a fact that there is no such thing as an infallible biologic law? Observations of others cannot be disregarded which place considerable doubt on the infallibility of determining the definite period of ovulation and conception. Every bit of evidence should be considered in this controversy, and considerably more must be submitted before a verdict can be arrived at. The popularization of the thought that there exists a sterile period in women has been fostered through the issuance of books in which the subject unfortunately is smothered in a conglomerate of facts enthusiasm, sophistry and overemphasis of certain half truths. Not one of these books so far has added much to the solution of the question. The problem is still subject to debate and the public should be informed that the matter is not settled.

Recovery of Influenza Virus—Andrewes and his collaborators recovered a virus pathogenic for ferrets from four teen cases of influenza, five in 1933, one in 1934 and eight in 1935. Their successes occurred at times of prevalence of a form of infection of the upper respiratory tract of high infectivity. No virus was recovered from sporadic cases diagnosed as influenza. These observations support the view that what is commonly regarded as influenza is not an entity. It becomes, therefore, a matter of prime importance to find, if possible, some means of differentiating clinically between the disease caused by a ferret-pathogenic virus, which they identify as epidemic influenza, and other conditions resembling it. It is, of course possible that some of the sporadic cases are due to an influenza virus in which lessened infectivity for man is associated with failure to adapt itself to the ferret. The finding of antibodies active against the human strain of virus in most adult serums is of great interest and needs further study in relation to immunity or susceptibility to infection. At present it is not known whether people having antibodies in their serums are immune to an attack of the disease or not. Francis and Magill found no antibodies to the virus in persons in the acute stage of influenza, but these developed during convalescence. In ferrets the immunity wanes during the six months following infection, and the animals regain some susceptibility at a time when antibodies are still demonstrable in their serums. The antibodies to swine influenza in adult human serums may possibly be nonspecific in the sense that they represent past contact not with that virus but with some unknown related antigen. But if they are regarded as possibly specific, an interesting field for speculation and research is opened up. Neutralizing antibodies to human (WSN) influenza virus were found in the majority of human serums examined. Their incidence was rather lower in children less than 10 years of age than in older children and adults. Neutralizing antibodies to swine influenza virus were regularly present in adult serums but were wholly absent from the serums of fourteen children less than 10 years of age. Influenza virus passaged through ferrets failed to infect two human volunteers by the intranasal route. Both these volunteers had neutralizing antibodies in their serums before the test was made.

Leukemic Infiltrations—Cleland gives examples of (1) leukemic infiltration of heart muscle, in one case causing sudden death in a seemingly healthy man, (2) leukemic infiltration of the kidneys or pancreas to a degree calculated to embarrass the functions of such organs, (3) leukemic cerebral accidents in which white cells form conspicuous accumulations, mostly from the associated hemorrhage, and (4) neoplastic-like deposits of seemingly leukemic cells in various organs and tissues in known or presumed leukemic cases and in cases that have not shown any alteration in the blood picture (pseudoleukemia). Examples are given of infiltrations in lymphosarcomatosis. The author finds it difficult to decide in some cases whether the condition is a lymphosarcoma or a pseudoleukemia. He is not satisfied that there is a sharp line of demarcation between these. Examples are also given of infiltrations in acute cases of Hodgkin's disease and Hodgkin's sarcoma of Ewing. The presence, even in small numbers, of reticulum cells with compound or multiple nuclei is a help in diagnosis and enables some cases resembling lymphosarcoma to be reasonably transferred to this group.

Treatment of Pneumonia with Injections of Alcohol—Bakshi and Andreasen employed a solution of 20 per cent alcohol in physiologic solution of sodium chloride in the treatment of six cases of uncomplicated lobar pneumonia. The dose, injected intravenously, varied from 20 to 25 cc daily. They found later that the strength of the solution could be increased to 33 per cent without causing any more reaction than previously. In one case they had to give two injections of 12 and 10 cc daily, owing to constant rigors which single doses of 20 cc produced. In all the other cases the reaction to the injection was slight and limited to a feeling of chilliness from about twenty to forty-five minutes after the injection. Subcutaneous infiltration due to faulty technic in puncturing the vein produced momentary pain running up the arm. Slight induration without suppuration at the site of injection was the only sequel observed when the needle either slipped out of the vein or transfused it. Within an hour of the injection there was sufficient decrease in the intensity of the pain in the chest to allow the patient to sleep comfortably. It had completely disappeared within forty-eight to seventy-two hours after the first injection. After slight stimulation during the injection in some cases there was steady decrease in the coughing. Cyanosis remained entirely insignificant throughout the course of the disease in cases in which the injections were commenced from the first or second day of disease. In the majority of

cases the respiration rate was lowered and the dyspnea much reduced. The pulse rate was slightly lowered. There was some rise of temperature after each injection, the rise decreasing gradually as the patient's condition improved. The temperature remained raised until the crisis occurred at the eighth or ninth day, just as in an untreated case of pneumonia. Arrest of the process of consolidation in cases treated from the start of the disease was remarkable. The congestive stage gradually regressed so that by the time the crisis occurred the involved lobe was almost free from any signs of pneumonia. In two cases in which alcohol was not commenced until the fifth day of the disease and consolidation had already set in, resolution was rapid. Except in one case in which the leukocyte count rose from 8,500 to 12,800 after the first injection, there was a gradual decrease running parallel with the regression of the lung signs and the improvement in the general condition of the patient. The course of the disease, from the rise of temperature on the first day to the fall on the eighth or ninth day by crisis was the same in cases treated with alcohol in those partially treated with alcohol and in those not treated by alcohol. The complications, i. e., lung abscess and acute nephritis, were beneficially affected by the alcohol. The subjective condition of the patient was immediately changed from that of the acute distress of the pneumonic patient to one of ease and sleep. The foregoing treatment is now being applied by one of the authors to postanesthetic and postoperative lung complications.

Injection of Histamine in Rheumatism—Eastwood states that beneficial effects were obtained with histamine in instances of almost all types of rheumatism, though not in every individual case. Patients having periarthritic arthritis of the small joints of the hand, impairment of the grip and cold and cyanotic fingers gave the best response. The worst type of response to the drug was in cases in which no circulatory disturbance was demonstrable. The most immediate and constant effect was flushing. A second effect of histamine was the relief of pain with an increased range of movement of the joints. Both of these generally occurred within two or three minutes of the injection although occasionally there was a latent period of some hours. Histamine relieved vasomotor symptoms. The patients experienced a sensation of general bodily warmth even when erythema of the skin was not observed. This feeling of heat lasted some hours and then tended to subside a lesser degree remaining for several days. While the face was flushed fulness and throbbing of the head were common sometimes actual headache and sometimes dizziness. These effects lasted from a few minutes up to half an hour. It was found that headache might almost always be avoided if the patient lay down for half an hour following the injection. With histamine there was usually a fall in blood pressure of from 20 to 40 mm of mercury, returning to normal within five minutes. If the blood pressure was initially high the fall tended to be somewhat greater. With thiohistamine the blood pressure was but rarely affected and then only by the larger doses. The foregoing effects were constant and usual, but sweating, drowsiness, appetite, well being, temperature, pulse, respiration and paresthesia were less constant.

and occurred in a few cases and therefore the author discusses them briefly. Whether the effects of histamine treatment are lasting and whether it can replace other forms of treatment have yet to be shown.

Use of Gonadotropic Substance in Undescended Testes—Spence and Scowen treated thirty-three patients aged 4 to 26 years having imperfectly migrated testes with the gonadotropic substance from pregnancy urine given in doses of 500 rat units intramuscularly twice a week. Both testes descended into the scrotum in six of the bilateral cases and one testis in four, while in two cases descent has not occurred. In eleven of the nineteen unilateral cases the testis descended and in two cases with the testis high in the neck of the scrotum a low position in the scrotum was assumed. Successful results were obtained within periods ranging from two weeks to fourteen and one-half months. The testes have remained in the scrotum in nine of eleven cases followed for from one to eleven months after cessation of treatment.

Propagation of Virus of Epidemic Influenza on Developing Egg—Burnet propagated the virus of epidemic influenza for fourteen generations on the chorio-allantoic membrane of the developing egg. It was initiated by inoculating eggs with a membrane filtrate made from nasal mucosa and lung of ferret 10 which was killed during the secondary temperature rise of a typical attack of ferret influenza. For passage membranes were removed from the egg to sterile solution of sodium chloride in a petri dish and examined for lesions with a lens against a dark background. Membranes with distinct lesions were then placed in broth tubes and left in the refrigerator till convenient. To prepare the inoculum the membrane was ground with quartz powder and 4 or 5 cc of broth. This was centrifuged at fairly high speed in an angle centrifuge for from five to ten minutes and the supernatant fluid inoculated. Characteristic lesions were produced the macroscopic and microscopic features of which are described. It is highly probable that in the near future attempts at immunization of human beings with killed or attenuated influenza virus will be made, and that the egg membrane technic may find an important practical application. It allows growth of influenza virus which is certainly free from contaminating viruses or bacteria and should almost certainly provide a much more suitable 'raw material' for the preparation of antigens than either ferret or mouse tissues.

Gastric Crisis of Tabes—Binet and Parrot studied the chloride metabolism in a patient having constant vomiting from a tabetic gastric crisis. They observed the chloride loss the level of blood chloride and the variations in blood urea. From these observations they concluded that the gastric crisis of tabes causes a condition of lowered blood chloride which perhaps explains the extreme depression of these patients. The crisis develops in three phases: nervous phase or dechloridation, humoral phase or stabilization of low chloride level, and critical phase or repair. It is not sufficient to treat the nervous factor by intravenous injections of atropine; rechloridation also is indicated. If begun on the first day, it should be sufficient to compensate for the chloride loss.

Colposcopy for Early Diagnosis of Cervical Carcinoma

—Bucher points out that the appearance of a vaginal discharge that has a reddish tint, the intermediate hemorrhages or hemorrhages occurring after examination, after coitus or after forced defecation are late symptoms, they indicate the terminal stage. Pain also is a late symptom, for by the time pain is felt the carcinoma has already spread to the pelvic connective tissue the peritoneum the sheath of the psoas and the ischiadic plexus. Carcinoma of the uterine cervix does not produce subjective symptoms during the early stage. He thinks that the early diagnosis of carcinoma of the uterine cervix is possible only if every woman beyond the age of 30 is subjected once a year to a thorough examination. The usual methods of examination are bimanual palpation and examination with the speculum. Palpation is the more valuable of these two methods, because the wall of infiltration surrounding the carcinoma can be better felt than seen. If it cannot be decided whether an area is carcinomatous or not an exploratory excision is advisable but is justified only if there is reason to suspect the presence of carcinoma. The author admits that for the practitioner it is extremely difficult to recognize the nature of changes in the uterine cervix merely by means of palpation and by inspection with the eye. A reliable serologic diagnosis would be of great help but although there are some promising methods none have as yet produced satisfactory practical results. For this reason hope lies chiefly in the improvement of the local methods of examination and in this connection the author mentions Schüller's iodine test and colposcopy which should be used together. Colposcopy is the stereoscopic observation of the cervix with centered illumination and considerable magnification. Colposcopy reveals that the cervical carcinoma does not necessarily appear in the form of nodules but rather in the form of peculiar epithelial changes. Hinselmann designates these stages as matrix regions. They appear as leukoplakia as well as under other forms. Later examination often reveals leukoplakia where previously other changes had existed. Histologic studies indicate the uniformity of the various changes, in that they reveal atypical epithelium with a tendency to cornification and to growth into the connective tissue and into the glands.

Approximately 20 per cent of the so-called matrix regions prove to be carcinomas. They are the symptomless incipient stages and their recognition by colposcopy demonstrates the great value of this diagnostic method. The matrix regions are removed by shallow amputation of the cervix. Thus cure is effected without great surgical risk and without danger of relapse. Moreover the uterus retains its functional capacity (menstruation and eventually pregnancy).

Puerperal Infections After Bath Before Delivery—To determine whether a tub bath or coitus during the last two weeks before delivery will increase the incidence of febrile temperatures and of inflammatory complications during the puerperal period, Koller studied 2,750 spontaneous deliveries and 922 cases in which the delivery had to be terminated by a vaginal or abdominal operation. In the women who had had a tub bath conditions were less favorable only in those who had to undergo a cesarean operation. However, the differences were not entirely outside the margin of error. In the group of women who had had coitus the febrile temperatures were more frequent among the spontaneous deliveries as well as among the surgical deliveries, however, the inflammatory complications did not show a higher incidence. The author concludes from his observations that a tub bath or coitus during the last two weeks before delivery do not justify an unfavorable prognosis for the puerperium. He hopes that this problem will be investigated further.

Necessity of Critical Investigation of Anamnesis in Case of Expert Testimony in Matters of Compensation R Bing—p 61

*Treatment of Delirium Tremens H Steck—p 68

Theoretical Considerations Regarding Jejunal Ulcer After Gastro-Enterostomy P Decker—p 73

*Type Diagnosis of Paratyphoid B Group C Hallauer—p 77

Treatment of Delirium Tremens—According to Steck, the treatment of uncomplicated delirium tremens is done best without the use of narcotics and without alcohol. He shows that the mortality rate is high in institutes in which alcohol is given to patients with delirium tremens, whereas it is low in institutes in which no alcohol is given. With regard to the use of narcotics, he says that patients with delirium tremens are generally refractory to moderate doses and that the doses which would be effective involve the danger of impairment of the centers of the medulla oblongata. In this connection he mentions morphine and scopolamine the use of which has been discontinued because it involves danger. However, chloral hydrate and paraldehyde are still being used. The author considers inadvisable confinement in the cell as well as the use of straps and strait-jackets, but he has found the use of a bed with a grating quite helpful. The grating should be constructed of ropes rather than of metal. If this type of bed is used the patient can move freely in his bed and is not likely to injure himself. The author points out that if the use of this type of bed does not seem desirable, paraldehyde may eventually be tried. However, in cases in which careful watching is possible, he considers an insulin carbohydrate treatment advisable. Insulin has been used in the treatment of delirium tremens because of its action on the hepatic disturbance that exists in these patients but the author noted that it also has a general sedative effect. To be sure a hypoglycemic shock must be carefully avoided because patients with delirium are predisposed to epileptic attacks. The patient should be given in the morning from 5 to 10 units of insulin after an hour this dose should be repeated and after another hour 60 Gm of sugar should be given diluted in water or coffee. If necessary the sugar may be given after the first dose of insulin. The author attaches especial importance to the dietetic treatment. If the treatment is carried on without the use of narcotics large quantities of fluids should be given such as coffee with milk, tea and fruit juices. The food should provide large amounts of carbohydrates but should be deficient in fats and proteins. The circulation and the cardiac action must be supported by the administration of heart stimulants. In cases in which the renal function fails resection with subsequent infusion of sodium chloride solution may eventually be helpful or salyrgan may be tried cautiously.

Type Diagnosis of Paratyphoid B Group—Hallauer shows that the type differentiation is important as it gives information about the course the infection will take. An infection caused by the Schottmüller type usually takes the course of an abdominal paratyphoid. The incubation period lasts from three to six days and the characteristic symptoms are splenic tumor, roseola, leukopenia and slow pulse. It persists for about twenty-one days and carriers are quite frequent in this type. The paratyphoid of Breslau type, however, is usually characterized by an acute gastro-enteritis, it lasts only a few days and carriers are rare. The Schottmüller type of infection is usually transmitted by direct contact, and thus sporadic cases are more frequent than group infections, whereas in the case of infections with the Breslau type mass infections predominate. The author made bacteriologic studies in two minor epidemics of paratyphoid. The first epidemic could be traced to a paratyphoid carrier in a dairy. In the course of two months the author observed twenty-six cases. The incubation period averaged six days and the symptoms were usually like those of typhoid and persisted for about eighteen days. The feces contained paratyphoid B bacilli as a rule up to the third week, but in two cases they were still present after seven and eight weeks. All strains obtained in pure culture were of the Schottmüller type. The second paratyphoid epidemic occurred in an institution and could be traced to infected milk. The cases occurred almost simultaneously and all presented the aspects of an acute gastro-enteritis lasting only a few days. The author examined five specimens of feces, in two he detected B enteritidis Breslau and in the others he found paracolon bacilli. After a strain had been found to belong to the paratyphoid B group it was subjected to type differentiation. The cultural method of type differentiation was done by testing the strain with d-tartaric acid and with rhamnose and by watching for the formation of mucous walls on the agar plates. The Schottmüller type was found to react negatively to tartaric acid and to rhamnose and was found to form a wall of mucus, whereas the bacilli of the Breslau type showed the opposite behavior in all three tests. The serologic type differentiation was done first on the slide and eventually also by detailed agglutination tests with type specific serums.

Resistance of Erythrocytes in Tuberculosis in Children—Andreucci made determinations of the resistance of the erythrocytes in the blood of thirty-two children of both sexes, ranging from 3 to 12 years of age and suffering from tuberculosis in different stages of evolution and in any one of the following localizations: lungs, bones, lymph nodes or peritoneum. For evaluation of his results he used Viola's formula for the maximal mean and minimal globular resistance of the erythrocytes (R1, R2 and R3 respectively). The maximal resistance of the erythrocytes (R1) was greatly increased in all the cases of the author. The mean resistance (R2), regardless of the localization of tuberculosis, was increased in the most serious cases of the disease and normal or diminished in the few cases of patients who were recovering. The minimal resistance (R3) was normal in all cases. The author states that his results point out that the reticulo-endothelial system is insufficient in tuberculosis. Its insufficiency is manifested by the defective hemocatheretic action of the system on the erythrocytes especially on those already mature but recently entered into the circulation and which constitute the group of the first resistance. In grave cases of tuberculosis the insufficiency acts also on the erythrocytes that constitute the group of the second resistance that is those which have been forming the mass of the blood longer than those of the former group. However in grave cases of tuberculosis in patients of general good condition and with a tendency to improve, the insufficiency of the reticulo-endothelial system does not manifest itself, owing to the fact that in these cases the system

has regained its normal activity. These facts explain the constant increase of the first globular resistance in all the cases of this group, that of the second resistance in the most serious cases and the normal values of the second resistance in cases tending to improve, and that of the third resistance in all cases.

*Value of Methods for Investigation of Functions of Pancreas and Exocrine Functions of Pancreas in Diabetes Mellitus G Barbera and G Adinolfi—p 27

Bilateral Collapsotherapy Cases L Barchi and G Iaconini—p 42

Functions of Pancreas in Diabetes Mellitus—Barbera and Adinolfi determined the diastases and lipases in forty-nine patients suffering from different diseases. Twenty-one patients of the group had diabetes of either a mild or a grave form. The authors used Wohlgemuth and Rona-Mellis tests for determining the diastases in the blood and in the urine and the lipases in the blood, respectively. The results of the tests, which were verified by studies made on the duodenal secretion as well as by the observations made during operation in three cases and at necropsy in two cases, confirm their dependability. In relation to the results obtained in the group of diabetic patients the authors conclude that the content of diastases in the blood and in the urine is diminished and that of lipases in the blood increased in all cases of grave pancreatic diabetes. The results of the authors' work, as well as those reported by the use of Wohlgemuth and Rona-Mellis tests, indicate that in cases of pancreatic diabetes there is neither independence nor antagonism between the functions of the internal and external secretions of the pancreas but that grave lesions of the acinar portion of the gland coexist with those of the insular portion of the organ. The authors obtained satisfactory results by the administration of raw pancreas or of a preparation of dry pancreas. The treatment results in increasing the diastase content of the blood and the urine and diminishing the lipase content of the blood of the patients.

Banti's Syndrome Case I L Resio—p 134

Bilirubin in Blood Serum in Diseases of Biliary Tract—Bengolea and his collaborators made determinations of the direct (biliary) and indirect (blood) bilirubin in the blood serum of seventy-six persons, including normal persons and patients suffering from jaundice or other pathologic conditions unrelated to the biliary tract. The author concludes that direct bilirubin does not exist in the blood serum of persons having a normal liver. Its presence in the blood indicates lesions of the trabeculae of the liver with formation of fissures through which direct bilirubin passes from the bile capillary to the blood capillary side. Fiessinger's schemes for interpretation of the mechanism of entrance of direct bilirubin into the blood in relation to the extension of the trabecular injury in the several types of jaundice are exact but they should be modified in accordance with the fact of the existence of two types of bilirubin for a better interpretation of their significance. The presence of an increased amount of indirect bilirubin in the blood serum of icteric patients is an important index of extensive injury to the liver associated with functional insufficiency of the organ, provided the presence of hemolytic jaundice can be excluded. This statement was proved in the authors' cases by the fact that while the figures of indirect bilirubin in the blood serum of icteric patients who were suffering from liver insufficiency were high, those in icteric patients who did not develop hepatic insufficiency were either normal or slightly increased.

Sensitization of Skin to Autoserum—Bizzozero describes studies on twenty-five patients to whom he administered intracutaneous injections of 0.2 or 0.5 cc of their own serum. Often he made the injections several times at the same site, usually the external surface of the arm. In thirteen cases the reaction was negative, that is, no changes of any kind were observable after several injections and in three cases a slight temporary infiltration resulted, but in spite of this the author counts these three with the negative cases. In nine cases the reaction was positive. In these cases the first intracutaneous injection of autoserum as a rule caused no changes or only a mild infiltrate which disappeared again in from twenty-four to forty-eight hours. Repeated injections at the same site, however, resulted in a slightly elevated, rather firm nodule, which persisted unchanged for from twenty to forty-five days and then subsided gradually. Moreover, if now the same quantity of serum was injected near the first nodule, there often developed within a few days a slightly erythematous nodule, which as a rule was somewhat less elevated and infiltrated than the first one. When these nodules were rubbed lightly, they swelled up and resembled pigmented urticaria. In three patients, in whom the nodules were especially prominent, he noted that, whereas previous to the autoserum injections the intracutaneous injection of auto blood caused not the slightest reaction, the same injection, when made in the surroundings of the nodules, caused a large wheal which in the course of the following days developed into a deeply infiltrated, erythematous nodule. In one of the three patients the nodule appeared without the preliminary wheal formation. Injections with Locke-Ringer's solution, which served as control tests, gave negative results. The author made histologic studies on two nodules that had developed after the injection of autoserum. He observed a tuberculoid structure. He reaches the conclusion that substances are formed within the serum, either after it has been withdrawn from the organism or after it has been reinjected, which sensitize the skin of the patient against his own serum or against his own blood. The reaction can probably be traced to an antigen antibody reaction.

Chorionepithelioma and Its Hormonology—Mandelstamm describes four cases of chorionepithelioma, the first of which was detected in time by the Aschheim-Zondek reaction and showed peculiar hormone conditions during the postoperative period. The third patient died and the others recovered. The latter were kept under observation for several years, the urine being subjected to the test from time to time. The author reviews a case that was recently described by Siegmund and as far as the postoperative hormone reactions were concerned resembled the first of the cases described by him. He points out that Siegmund gained the impression that the appearance of positive urine reactions following the removal of a cystic mole was caused by a storage of the hormones in lutein cysts and the author thinks that in his (first) case the positive urine reaction may likewise have been caused by a lutein cyst. He stresses that his own case and that described by Siegmund demonstrate how carefully the recurrence of positive urinary reactions must

be evaluated before they are considered an indication for irradiation or for surgical treatment. He does not consider a single positive reaction an adequate reason for a radical intervention and thinks that the extirpation of the ovaries in Siegmund's case was not justified after the character of the tumors had been recognized during the operation.

Influence of Amniotic Fluid on Contraction of Uterus

—Fomina reviews the literature on the genesis, composition and hormone content of the amniotic fluid and then reports his investigations on the influence of the amniotic fluid on the contractile action of the uterine musculature. He reaches the following conclusions: 1 The function of the amniotic epithelium and the excretory action of the fetal kidneys are the chief factors in the development of the amniotic fluid. 2 The amniotic fluid has a myotonic effect that increases as pregnancy progresses. 3 The amniotic fluid of a pregnancy that has been brought to term also exerts vasopressor actions. If the amniotic fluid is treated according to the method employed to extract the solution from the posterior lobe of the pituitary body, the dry residue that is obtained has myotonic as well as vasopressor characteristics and resembles extract of posterior pituitary. The author tested the extract from the amniotic fluid on the uterus of rabbits and of guinea-pigs and also investigated its influence on the blood pressure of rabbits and cats. He reaches the conclusion that the amniotic fluid as well as the extract obtained from it might eventually be used for the purpose of increasing the contractile action of the uterus.

Ovarian Tumors—Schiller points out that the question as to the manner of the transformation of the sex characters under the influence of masculating tumors can be answered only on the basis of the observations and opinions regarding the determination of sex. He points out that, whereas for a while it was believed that sex is determined by the hormones, it has been asserted also that the primary fixation of sex takes place on the zygotic, chromosomal basis. Cytologic studies on the sex cells indicated the possibility of a progamous and of a syngamous fixation of sexuality. To be sure, the complete post-embryonal development and maturation of the congenitally conditioned sex organs and sex characters is effected by the influence of hormones. The author points out that at present it is generally believed that although the hormones exert a protective influence on the sexuality the primary fixation of the specific sex characters nevertheless is lodged in the chromosomes. However, experiments have revealed that this so-called zygotic determination is by no means entirely fixed and unchangeable. In giving his attention to the masculation of women under the influence of some ovarian tumors the author considers it doubtful that the progamously or syngamously determined chromosomal constitution can be influenced later by internal or external factors. He considers it more likely that the hormones produced by the tumor stimulate and develop latent primordia. He stresses that a causal connection between tumor and masculation is definitely proved only if the symptoms of masculation disappear following the extirpation of the tumor. Considered from this point of view there are only three types of tumors that are connected with masculation: (1) ovarian tumors the structure of which resembles the male gonad, (2) lutein tumors and (3) adrenal tumors. The author discusses these tumors and their action.

Placental Theory of Eclampsia—Ulesko Stroganowa describes experiments he conducted to determine the role of the placenta in the pathogenesis of eclampsia. He reached the conclusion that two factors must be considered in investigations on the pathogenesis of eclampsia: (1) the flooding of the maternal blood with decomposition products of the diseased placenta (in addition to the normal secretions and excretions of the placenta) and (2) the resistance of the maternal organism. The complex organic disorders that appear in toxemias of pregnancy are the result of the placental decomposition products that have entered the blood stream. Similar disturbances may develop in severe infections but in the ovaries only placental decomposition products and the hormones contained there effect specific changes. The ovarian changes consist in the appearance of numerous corpora lutea, particularly those of the pseudo type, rapid growth and destruction of follicles, luxuriant growth of

the interstitial gland and severe hyperemia. Moreover, if the increased activity of the adrenals and of the thyroid is taken into consideration, it is evident that to the disturbances in the general condition there is added a disturbance in the correlation of the endocrine system. The author points out that recent studies have revealed an increased functional activity of the posterior lobe of the hypophysis in patients with eclampsia. He thinks that the organic changes which become manifest in edemas, extravasations of blood and necroses and which indicate a disturbance of the vascular system correspond with the observations described here.

Twenty-Four Hour Rhythm of Blood Sedimentation

—Jores and Strutz point out that, since the form elements of the blood as well as some of the constituents of the plasma are subject to rhythmic fluctuations, it was to be expected that the sedimentation speed of the erythrocytes likewise undergoes rhythmic changes in the twenty-four hour period. They made investigations on persons with normal sedimentation values as well as on some with abnormal values. In those with normal sedimentation it was found that if the withdrawal of the specimens is begun in the morning, the curve shows at first a decreasing tendency. Beginning with 10 a m the curve shows an upward trend which reaches its maximum at about 4 p m. Then there is a slight downward trend until 8 p m which in turn is followed by a slight and brief upward trend, to be followed again by a downward trend, which reaches its lowest point at about 6 a m. In the cases showing abnormal values of the sedimentation speed similar twenty-four hour curves were observed. The authors discuss the various factors that might play a part in the development of the rhythmic changes. They do not think that the food intake or physical exercise exerts an influence. Moreover they were unable to corroborate the observations of Imanow and Basilewitsch, according to which the gastric motility influences the sedimentation speed. In further studies they found that the examination of different patients on the same day resulted in similar curves, whereas the examination of the same patient on different days resulted in different curves. They reach the conclusion that in the practical employment of the sedimentation test, it is important to pay attention to the time of day at which the specimen is withdrawn, for a sedimentation value that is pathologic in the case of a morning specimen may still be normal if it concerns an evening specimen. Moreover, the authors observed two cases in which the sedimentation values were normal in the morning but pathologic in the evening. In both instances this proved to be of diagnostic significance. One patient had a lymphogranulomatosis, the other a postanginal sepsis. In the latter case the pathologic sedimentation values that appeared in the evening hours indicated a latent infectious process.

Isolated Tuberculosis of Rib Cartilage—According to Muhlfelder conditions necessary for embolic infection of a rib cartilage are furnished by the central localization of its arteries and in particular of its terminal arteries. The infection extends by invading the neighboring cartilaginous tissue. The structural characteristics of the cartilage render it particularly vulnerable to the toxic effect of the invader. The serpiginous mode of

extension of the lesion is responsible for the frequent recurrence after operative removal. Radical operative removal is the only successful therapy of this condition. In cases in which there is fistula formation the latter may first be curetted and the patient allowed to become afebrile. Analysis of the cases treated at the surgical clinic of the University of Basel disclosed that the condition is found with greatest frequency in the middle aged and that the seventh, ninth and eleventh ribs are most frequently involved. The clinical course was exceptionally mild. There was almost no localized pain. Henschen's observations on the blood supply of a rib cartilage and on the formation of a medullary cavity were substantiated in the course of operations on these patients. Henschen's operative method consists of first aspirating the liquid contents with a syringe and then destroying the lesion with a diathermy point.

Sarcoma of Breast—Rose states that among 660 cases of malignant neoplasm of the female breast in which operation was performed at the surgical clinic of the University of Leipzig between 1913 and 1934 there were sixteen (2.1 per cent) cases of sarcoma. Of the latter the most frequent form histologically was the spindle cell sarcoma. It is relatively benign being characterized by slow growth and little tendency to metastasize. The round cell, the giant cell and the melanotic sarcomas occur far less frequently but run a rapid and malignant course. The average age incidence was 40 years. Lactation, menstruation, pregnancy and trauma were mentioned in four cases as contributing factors. The left breast was more frequently involved than the right. The sarcomatous breasts enlarged more rapidly than the carcinomatous breasts. Sarcoma does not exhibit a tendency to invade the pectoral muscles or the regional lymph nodes. They metastasize into the lungs or the liver by way of the circulation. The prognosis in sarcoma is more favorable than in carcinoma. There were 71 per cent permanent recoveries in their material among the former. Of a total of 745 observed cases of breast neoplasms eighteen were of the male breast (2.4 per cent). Twelve of these were carcinomas, two sarcomas and four adenofibromas. The most frequent form was the simple solid carcinoma while the adenocarcinoma and the medullary carcinoma were rare. The average age incidence was 59 years. Trauma was frequently mentioned in the histories. The right and left breasts were involved with the same frequency. The course of the growth is slow, the tumor seldom acquiring greater size than a plum or a small apple. The tumor is frequently attached to the skin and the pectoral muscles and presents an ulcerating surface. The regional lymph nodes have undergone malignant degeneration in 60 per cent of the cases. Body metastases were found in the vertebrae, ribs, pleura and lungs, liver and supraclavicular lymph nodes. Permanent cures were few. Only three patients survived the five year period. Sarcomas of the male breast are less frequent. When they occur as the spindle cell variety, they are characterized by slow growth and little tendency to metastasize. They were found to be free from metastases five years after the operation. The pericanalicular fibro-adenoma presents itself as a superficial, hard, freely movable tumor. It is benign and does not recur after extirpation. There were three cases of gynecomastia, one of which exhibited a definite heterosexual character dependent on the disturbance of the internal testicular secretion while in the other two the disturbance was apparently in the primordium.

Bovine Tubercle Bacilli and Human Tuberculosis—

Goeters described his studies on the strains of tubercle bacilli obtained at the pathologic institute in Leipzig from 135 cases of tuberculosis. In sixty-seven cases of chronic pulmonary

tuberculosis with extensive cavity formation he detected the bovine type four times. He also detected the bovine type in two out of fifty-one aged persons with tuberculosis. In eleven cases of new pulmonary tuberculosis with nontuberculous intercurrent diseases and in six cases of miliary tuberculosis of the lungs he always detected the human type of tubercle bacillus. Thus there were six strains of the bovine type in a total number of 135 strains that is 4.4 per cent. The author points out that this incidence corresponds with that reported by Griffith and Munro (4 per cent), but he admits that in a selected necrotic material of 183 cases Griffith observed bovine infections in 29.7 per cent of the cases. In discussing the cases with bovine infections in his own material, the author points out that two of his cases concerned children who had a caseous tuberculosis of the mesenteric lymph nodes and an extensive intestinal tuberculosis that is, the tuberculosis was probably an ingestive infection. In the two adults of the group with chronic pulmonary tuberculosis, droplet or dust infection in the course of contact with tuberculous cattle must have caused the infection with the bovine type. Neither of these two patients had intestinal ulcerations and it can hardly be doubted that the infection was air borne. But although the infection by cattle seems most likely in these two cases, a transmission from man to man cannot be definitely excluded. Of the two aged persons in whom bovine bacilli were found, one had a mixed infection of the lungs (human and bovine types). However, simultaneously existing intestinal ulcerations contained only bovine bacilli. The author assumes that the bovine infection of the lungs was probably a metastatic process of the intestinal infection, for the tuberculous lesions in the intestine were older than those of the lungs. The other case of bovine tuberculosis in the group of aged persons concerned a rural laborer with a new aerogenic infection of the lungs without intestinal involvement.

Number of Leukocytes in Treatment with Arsenic—Halter studied the number of leukocytes in twenty six patients with psoriasis and in fifteen patients with various dermatoses, all of whom received injections of arsenic preparations. He observed a decrease in the leukocytes in thirteen of the patients with psoriasis and in eight of the fifteen patients with dermatoses while an increase in the leukocytes was noted in only one of the patients with psoriasis and in none of the patients with dermatoses. The author thinks that such an incidence of reductions in the number of leukocytes cannot be said to be within the scope of physiologic fluctuations. Moreover, he does not think that it can be ascribed to a subsidence in the inflammatory processes existing at the beginning of the treatment, because the leukocytes were found to increase again after cessation of the treatment without there being a recurrence of the inflammatory manifestations but rather a further improvement. The author stresses that the reduction of leukocytes was noticeable in only some of the cases in which other signs of arsenic intoxication (gastro intestinal disturbances, keratoses and so on) appeared, but it did appear in cases in which these other toxic symptoms were not evident, that is it may be the only indication of a toxic action of arsenic. He concludes that in patients who receive arsenic treatment the number of leukocytes should be regularly controlled.

- *Gustatory Disturbances in Influenza W. Schwanke—p 93

Determination of Vitamin C in Urine—Ammon and Hinsberg show that the various chemical methods for the determination of vitamin C in the urine are incorrect. The capacity of the urine to bind iodine is not suited for the quantitative determination of the vitamin C content, because ascorbic acid is not the only reducing substance in the urine. An addition of potassium iodide reduces the iodine number greatly but the true vitamin C content is not determined. The authors think that the indophenol method likewise produces excessive

values, but they believe that the methylene blue method according to Martini and Bonsignore discloses values that are nearer to the real ones. Attempts to develop other methods, in which the removal of the reducing substances and the coloration of the urine were the most important factors, have failed so far. The authors studied also the vitamin C content of the placenta. The iodine test as well as the indophenol method indicated relatively large quantities of cevitamic acid, and the methylene blue method revealed the presence of 1 mg per hundred grams. The authors reach the conclusion that all reduction methods are only makeshifts and must remain unsatisfactory, because there is always considerable uncertainty as to whether other substances are included in the determination. The problem of vitamin C metabolism can be solved definitely only by means of a reaction that is specific for the vitamin and permits a quantitative determination.

Gustatory Disturbances in Influenza—Schwanke reports that he observed four patients who developed disturbances in the sense of taste in the course of influenza. The patients complained that no matter whether they ate sweet, sour or other foods they always experienced a bitter taste. They found this extremely unpleasant. The olfactory sense was not impaired in these patients. The severity of the influenza had no effect on the appearance or on the duration of the gustatory disturbance. The author emphasizes that these gustatory disturbances are of an entirely different nature from those that develop in case of lingual diseases (glossitis, atrophic tongue and so on), for, while the latter are due to local disease of the tongue, those occurring in influenza must be due to a disease of the innervating nerves or of the gustatory center, because the tongue showed no pathologic changes and the excretion of bitter substances (as in the case of some intravenous injections) likewise could not be proved. The author points out that influenza is often accompanied by mild forms of neuritides and he thinks that the gustatory disturbances correspond to the paresthesias observed in neuritides. He admits that in one of his patients a circumscribed form of encephalitis existed. He concludes that gustatory disturbances may occur in all diseases that lead to neuritides or to disturbances of the central nervous system. Whether they are more frequent in influenza than in other disorders will require further investigations.

*Origin of Diastasia in Pneumonia. I. Pavel, I. Radvan and B. Volovici—p. 133

Origin of Diastasia in Pneumonia—Pavel and his associates studied the influence of the body temperature on the course of diastasia and diastemia in patients with pneumonia. They observed pathologic diastemia and diastasia but these disorders did not run parallel with the temperature. In the majority of cases they observed the pathologic diastasia in the terminal stage of the disease or in the period of crisis. They observed also that the diastase content of the blood and of the urine run parallel a factor that excludes the possibility of a renal involvement in diastasia. After ascertaining that the leukocyte ferments can be excluded as a causal factor of diastasia, the authors think that there remains no other explanatory factor than the development of a pancreatitis during pneumonia. Functional studies in the course of pneumonia and anatomic observations on the pancreas of one patient lead them to conclude that the pancreas is impaired in cases of pneumonia. On the basis of the fact that the pathologic diastase values appear simultaneously with the glycoregulatory disturbance, they believe that there is a connection between these two manifestations and think that the glycoregulatory disturbances might be explained as the result of pancreatic lesions without the involvement of other organs. In evaluating the practical importance of this problem they state that among the infectious processes that cause an exacerbation or diabetes

mellitus pneumonia plays the most important part and that in order to avoid this exacerbation it is necessary to increase the insulin dosage considerably. They point out that such cases have been designated as insulin resistant, but they are of the opinion that this condition can be explained differently. They think that the increased diastasia is the sign of an excessive permeability of the cells in the region of the pancreas. Moreover, they believe that the increased permeability applies not only to amylase but also to other ferments, particularly trypsin, and that a disturbance of the insulin by excessive amounts of trypsin is an important factor in the larger insulin requirements.

Processes of Immunization in Hyperthyroidism—Bauer and his associates observed that, if rabbits are given subcutaneous injections of small doses of thyroxine intermittently over a period of from six to eight weeks they develop a resistance to thyroxine and finally no longer react to the injections with a reduction in the lipase and in weight. The serum of the animals that had become resistant to thyroxine, in contradistinction to the serum of normal rabbits, gave a complement fixation reaction with thyroxine. The authors state that this phenomenon is analogous to observations which other investigators made with gonadotropic substance. The observations they had made on rabbits induced the authors to test the serum of patients with disorders of the thyroid for its complement fixation capacity, by using thyroxine as the antigen. They found that the serums of patients with exophthalmic goiter produce a complement fixation reaction with thyroxine, the reaction was positive in the severe cases but negative in the milder cases and in cases in which treatment had been successful. Of fifty controls without thyroid disease, forty-seven gave a negative reaction. Of the three positive serums in this group two were from patients with a positive Wassermann reaction and one from a patient with hysteria. Since it is known that antibodies against nonprotein substances have only a relative specificity and as a rule react also to related substances, the authors employed the complement fixation reaction not only with thyroxine as antigen but also with diiodotyrosine. They obtained the same reactions with diiodotyrosine as with thyroxine. There were no serums that reacted to only one of the two substances. In evaluating the significance of their observations, the authors are convinced that the antibodies, which are demonstrable in the serum of patients with hyperthyroidism by means of the complement fixation reaction, have nothing in common with the antithyroid protective substances of the blood for the latter substances are reduced in patients with severe hyperthyroidism, whereas the complement fixation reaction becomes positive in these patients. Moreover they think that the factors which elicit the complement fixation reactions with thyroxine and diiodotyrosine differ from the antihormones which Collip postulated as an explanation for the resistance that develops against endocrine therapy. They concede that they are as yet unable to explain why an immunity reaction is produced by a physiologic increment that circulates in the organism in increased quantities, but they emphasize that this phenomenon is truly an immunity reaction. Their studies indicated also that diiodotyrosine is not an antagonist of thyroxine, as had been assumed by some. They believe that it is a preliminary stage of the hormone which has an analogous although much weaker action than thyroxine.

Abnormal Shortness of Allantoic Stalk and Its Results—Politzer describes a human embryo, which was approximately 8 mm in length and in which the axis had been turned 90 degrees. He shows that the curvature of the embryonal body was caused by an abnormal shortness of the allantoic stalk.

He suggests that this deformity may be the preliminary stage of congenital scoliosis, torsions of the vertebral column and other defects

*Striae of Nail in Arsenical Polyneuritis R A Mees—p 312

Lead Poisoning in Cigar Makers—Jordans and his associates describe the case histories of six cigar makers who were suffering from lead poisoning and state that this occurrence has not yet been reported in the literature. They think that lead poisoning of more or less degree is frequent in cigar makers and that pale, unhealthy looking persons of this trade justify the suspicion of chronic lead poisoning. The source of the poisoning is found in the zinc plates on which the cigar makers cut the tobacco. The authors conclude that the use of zinc plates for this purpose should be forbidden by law and that they should be replaced by wooden plates, which offer technical and hygienic advantages.

Striae of Nail in Arsenical Polyneuritis—In a patient suffering from polyneuritis produced by the administration of arsenic, Mees found that the typical transverse white striae of the nails, appearing some time after the ingestion of arsenic, contain six times as much arsenic as the ordinary nail substance. He states that the degree of sharp definition of the striae is related to the administration of one or more doses of arsenic, one dose producing sharply delimited striae while several doses cause the striae to be more diffuse. The forensic interest of the striae lies in the fact that the time of administration of the arsenic may be deduced from their appearance.

*Nerve Symptoms in Anemia Achylia Simplex L Abramson—p 358

Distribution of Platelets in Peripheral Blood—Beecher lists the physiologic number of platelets per cubic millimeter of blood according to the various methods of determination showing that some investigators consider the physiologic number to be 200,000 while others give values up to 900,000. He thinks that these wide variations are due to the fact that some fundamental condition has been disregarded. He describes observations that may account in part for the discrepancy between the various methods. The studies referred to were made with the Sandison Clark method. A window, which is placed in a rabbit's ear, makes possible observations at high magnification of the arterioles, capillaries and venules and of their contents in an intact animal and over a period of months. In observing the platelets in the circulating blood at a magnification of 400 diameters, a strikingly variable distribution of platelets was seen. A field with a moderately active circulation may be watched for a minute or longer and only an occasional platelet is seen passing through while at other times there are schools of them. From these observations the author concludes that one factor in the inaccuracy of platelet counting is the uneven distribution of platelets in the peripheral blood.

Posthemorrhagic Uremia—Meyler describes a form of extrarenal uremia that he observed in patients who became comatose after severe gastric hemorrhage. He first reports the observations on one patient in whom the necropsy revealed an ulcer with an open artery on the lesser curvature of the stomach. In order to gain a better insight into this form of uremia experiments were made on guinea-pigs and further clinical observations were made on several other patients. On the basis of these observations the author reaches the conclusion that posthemorrhagic uremia is due to the fact that large quantities of protein are destroyed and that the kidneys are not equal to the task of excreting the excess nitrogen. He points out

that this is a type of extrarenal uremia of which uremia due to hypochloremia and uremia caused by burns are the best known examples. He shows that all forms of extrarenal uremia are really originally "production uremias," for first there is an excessive production of protein and then the problem is whether the organism has a sufficient quantity of fluid at its disposal for the excretion of the excess of the nitrogenous waste products. It appears that people with gastric hemorrhage get into a serious condition of dehydration and it is shown that the dehydration leads to the often enormous toxic destruction of protein. That the uremia is not directly caused by the anemia was proved on guinea-pigs which were made anemic, were given considerable amounts of fluid by subcutaneous administration and did not pass into a state of uremia. Though the author does not suggest that in case of severe gastric hemorrhage death is caused by uremia, he thinks that the latter condition is nevertheless a serious complication, and he considers it advisable to administer large quantities of fluid in case of severe loss of blood.

Nerve Symptoms in Simple Achylous Anemia—After mentioning a number of investigators who observed acroparesthesia in patients with simple anemia and after citing one author who among ninety-five patients with funicular myelitis observed ten with a hypochromic blood picture, Abramson points out that according to some authors paresthesias occur in from 33 to 50 per cent of patients with hypochromic anemia. His attention was directed to this problem by observations on a patient whose history and appearance suggested a simple anemia but who had slight symptoms of myelopathy. In view of the latter symptom, pernicious anemia was thought of and the blood was examined. However, the examination of the blood as well as the further development of the disease confirmed the diagnosis of simple anemia. After this case the author examined eleven cases of simple anemia for possible nerve symptoms and he detected them in six cases. Ascending paresthesias in arms and legs were present in three, but these paresthesias disappeared completely in two and improved greatly in one, together with the improvement in the blood status. In two other cases the nerve symptoms had the character of mild polyneuritis, while in the remaining case some of the reflexes were abolished or weakened, but there were no paresthesias. The author emphasizes that all these cases presented the blood picture as well as the other symptoms of simple anemia and that the symptoms of anemia as well as the nerve symptoms disappeared in response to iron therapy. He thinks that the nerve symptoms of simple anemia often escape detection because they are usually mild.

Cancer and Tuberculosis in Alimentary Canal—Sifwenberg presents twenty-one cases of coincident cancer and tuberculosis of the stomach and thirteen of the cecum, and two additional cases of combined cancer and tuberculosis of the stomach and one of the cecum, all three diagnosed at the time the operations were performed. He says that in the stomach in which these cases usually occur in the cancer age, the cancer is as a rule primary and constitutes a favorable milieu for development of the tuberculosis, as in his second instance of implantation tuberculosis and presumably in the first instance in which the tuberculosis may have originated by the hematogenous route from the probable primary focus in the lungs. In the cecum the combination occurs at an earlier age and the tuberculosis is often primary, as in the third case described in which the tuberculosis is thought to have spread by the blood stream from the glands in the neck.

GASTRO-INTESTINAL ALLERGY

IV THE LEUKOPENIC INDEX AS A METHOD OF SPECIFIC DIAGNOSIS OF ALLERGENS CAUSING PEPTIC ULCER

L P GAY, MD
ST LOUIS

The introduction of the leukopenic index as a method of allergic diagnosis is due to the work of Vaughn¹ on the effect of milk on allergic individuals during the performance of tests for liver function according to the colloidoclastic crisis test of Vidal, Abrami and Iancovesco, which is dependent on a fall in blood pressure, a fall in the total leukocyte count, and a prolonged clotting time after the administration of 200 cc of milk. The pertinent observation was that milk did cause a leukopenia in those patients subsequently found to be sensitive to milk. By repeated tests on a known allergic patient who knew by experience that certain foods were capable of reproducing clinical symptoms on each occasion, the leukocyte response to compatible and to incompatible foods was studied. Those foods producing allergic symptoms were likewise able to depress the total leukocyte count while compatible foods were in general followed by a rise in the total count. In this way a new method of allergic diagnosis came into being.

Rinkel,² in the attempt to relieve an intractable asthmatic patient who gave a negative skin test, made a study of the leukocyte response to foods in that individual. He found that three foods alone produced a positive balance and that all others tested depressed the total leukocyte count. Reasoning that a positive balance indicated compatible foods and that a negative balance indicated allergens, the patient was limited to a diet composed exclusively of those foods which were followed by a digestive leukocytosis. The result of this test diet was a cessation of symptoms after a trial of three days. The importance of this experiment being appreciated, the method was then employed on a large series of patients with excellent results.

This method of diagnosis has been used with success in several types of allergy, namely, asthma, allergic headache, hypersensitive rhinitis and gastro-intestinal allergies of various types. The method though admittedly tedious, appears to be accurate to a high degree. Besides its accuracy, which alone is of great value, it is also helpful in those persons who, though suspected of being allergic, are test negative, and in that group of allergic individuals who react to every-

thing for which they are tested. Both types can, of course, be managed by test diets and food diaries, provided proper cooperation can be maintained over a long period of time. The food diary is a boon at all times, but delayed and accumulative reactions are at times difficult to recognize. A more accurate and expeditious method of recognizing this type of allergen is to be welcomed. Unfortunately, many gastro-intestinal reactions are entirely subjective and their recognition frequently depends on the acuity of the patient. Poor results may at times be traced to faulty interpretation rather than to poor cooperation.

The idea that peptic ulcer in many instances is an expression of anaphylaxis on the basis of the Arthus phenomenon is not new.³ Kern and Stewart,⁴ from clinical experience, have expressed the opinion that there is an allergic relationship in peptic ulcer. There is abundant experimental background for these opinions.⁵ This theory was put into practice, and a series of thirty-three cases of peptic ulcer treated by allergic management alone, with no medication, was reported in November 1934.⁶ These patients were put on three meals a day, only those foods being limited to which they had been proved to be sensitive by skin testing and by food diaries. As a person usually becomes sensitive to foods eaten regularly in the past, it frequently happens that the foods restricted are those most commonly used in the conventional ulcer diet. In spite of this unorthodox treatment, the results obtained over a period of forty months were most encouraging. Since that time and since the advent of the leukopenic index, another series of six additional cases has been studied. These cases were all examined roentgenologically as well as by the other customary laboratory procedures. They are all cases of definite peptic ulcer, confirmed by x-ray studies, by a continuation of symptoms after repeated trials of orthodox medical management, and in one instance by the recurrence of symptoms after surgical intervention. No particular attention was paid to the presence or absence of an allergic history in the patient's past record, as there has been no attempt to select favorable cases. They happen to be the first cases presenting themselves for treatment after the leukopenic index was adopted as a means of study.

In the beginning of this experiment, it was the practice to perform skin tests by the intracutaneous method and to omit those foods from the diet which gave the most strongly positive reactions. As this work progressed, it seemed more advisable to test the foods most commonly used and to omit the ones that pro-

2 Rinkel, L. I. The Leukopenic Index in Allergic Diseases. read at the thirteenth annual meeting of the Association for the Study of Allergy.

duced a negative balance. A satisfactory diet can be worked out more quickly this way and this procedure avoids one possible error that may occur if a food that has not been in the diet for several months is tested. If a previously restricted food is tested without its having been eaten a few times in the week preceding the count, a curve denoting compatibility may be obtained. Later curves may show a definite depression of the leukocyte count. An immediate depression of the count by a previously restricted food indicates a very toxic allergen, and it is not unusual for such a food to produce symptoms during the test period. It frequently occurred that there was a marked discrepancy between the skin tests and the compatible foods as determined by the feeding tests but this is to be expected as the etiologic diagnostic failure of the skin tests has been pointed out by numerous observers. Heretofore the only remaining proof has been reliance on a diary, but happily the leukopenic index has proved to be an aid of unexpected reliability and accuracy, not only in determining the allergic state but in determining the actual allergens at fault. Omission of foods producing a negative balance and the exclusive use of those producing a positive balance has resulted in cessation of symptoms and relief in every case so managed to date. Milk and wheat have been shown to be allergens in every instance and egg has been a compatible food in only three cases. As these foods are the ones most commonly used in ulcer diets and as they have been proved to be capable of reproducing symptoms on clinical trial after total omission it is not surprising that one characteristic of peptic ulcer is the cyclic recurrence of symptoms for many years. Wheat, milk and egg, however, are not the only foods that are to be omitted as each individual has different sensitizations to foods, and to get a good clinical result these particular sensitizations must be recognized and restricted.

As is shown in the tables, actual allergens depress the total leukocyte count very definitely. They are also able to keep the interval counts below the level of the fasting leukocyte count. At times there is also a curve which can be classified only as an indeterminate reaction. True classification of this type can be made by clinical trial or by the use of the questionable food as a gastric test meal and by observing the response of free hydrochloric acid to it. Because of the impression that the usual high acidity associated with peptic ulcer was probably caused by the use of incompatible foods gastric analyses were done at the same time as the leukopenic studies, specimens of blood and stomach contents being taken every twenty minutes and the food studied being used as the gastric test meal. Contrary to expectations, foods depressing the leukocyte count were also capable of depressing the free hydrochloric acid values in a majority of instances. Though this finding is not constant, as is shown by the charts, it is striking enough to be more than a mere coincidence. Compatible foods, or those showing a digestive leukocytosis were accompanied by a rise in the free hydrochloric acid curve. This again was not an absolute constant, but, as the additional information of the response of free hydrochloric acid was available those which increased the free hydrochloric acid response were judged to be compatible foods and were replaced in the diet. Clinical trial has proved this assumption to be true as each food that was indeterminate by the leukopenic index but was capable of increasing the free hydrochloric acid value has been asymptomatic in the diet. Foods that were

used as a test meal and were accompanied by lowered hydrochloric acid values have induced recurrence of symptoms on each feeding experiment. This has been true of the indeterminate types as well as of those giving a clearly marked incompatible curve. In this connection, the leukopenic index indicates the degree of sensitivity, as a marked drop in the leukocyte count coincides with a complete absence or marked inhibition of free hydrochloric acid. Foods of this type have always been immediate pain producers by the feeding test. These antigens were characterized in another way, that is, the ingestion of these foods caused an immediate and definitely excessive secretion of mucus which is analogous to an allergic reaction in any other mucous membrane. This may explain the lowered free hydrochloric acid value due to the buffer action of mucus. From repeated tests it is questionable whether actual protein is the buffer in this instance, since fruit and vegetable juices have been quite as effective in this regard as egg white, meat and fish. A delayed rise in the free hydrochloric acid value is common after the use of an antigenic food which has greatly lowered or inhibited the free hydrochloric acid response, and this observation may possibly account for the fasting hyperacidity usually associated with peptic ulcer.

REPORT OF CASES

The following case reports illustrate the use of, and the results obtained by, the leukopenic index in determining incompatible foods which, when eliminated, allow cessation of symptoms and which, when reintroduced into the diet, reproduce in detail the classic syndrome of peptic ulcer.

CASE 1—A J, a man, aged 33, a machinist, complained of tearing pain in the epigastrium about two hours after meals, which was relieved by food, and an aching pain in the lower lumbar region of the back. The onset of the pain occurred about nine years previously when a stomach disorder of a similar nature was present for about one month. This pain had recurred each spring with gradually increasing severity and duration but this year the pain had come on earlier and was much more severe. The present attack had been present for three months had been getting worse steadily and was preventing sleep. There was slight relief from heavy magnesium oxide and there was relief from night pain with food. There had been no vomiting until the first day of consultation. There was no blood in the vomitus and there had been no tarry stools. There was usually no nausea but gas and bloating were frequent. Belching was frequent and was accompanied by slight relief. The pain was in the epigastrium, it was not referred and it began two hours after meals. The pain was relieved by food and was partially relieved by alkali and by manual pressure over the epigastrium. The character of the pain was described as being tearing and burning. There had been a good appetite but the diet had been limited by various physicians previously consulted. There had been a tendency to rather marked constipation and liquid petrolatum had been taken each day. There had been a slight loss of weight during the past few months which the patient attributed to loss of sleep because of pain.

The past history was unimportant and there had been no manifestations of allergy. The patient's father died of heart disease, his mother was living and well, and he had two brothers living both of whom had symptoms of peptic ulcer. One of the brothers had had a gastro-enterostomy performed with a recurrence of symptoms. The patient was married. His wife and his two children were well. His wife had never had any miscarriages. He did hard work from 8 a. m. to 5 p. m. The habits of life were regular, he did not drink and he rarely smoked. He maintained his own home and had breakfast and dinner at home.

The patient was of sthenic habitus. The blood pressure was 95 systolic 60 diastolic. The weight was 59.5 Kg. The musculature was good but the nutrition was rather scanty. There

was a moderate erythematous spread when the skin was stroked. The pupils reacted to light and on accommodation. The nostrils were clear, the teeth were well kept and in good repair and the throat was slightly reddened. The thyroid was not palpable. The lungs were clear and there were no rales. The heart was regular and clear and there were no murmurs. On examination of the abdomen there was a point of tenderness in the epigastrium of about 2 degrees severity. All reflexes were normal.

Roentgenologic examination of the gastro intestinal tract revealed a deformed and tender duodenal cap making the diagnosis of duodenal ulcer highly suggestive. Other routine laboratory examinations were not significant. The results of the skin tests and leukopenic index studies are indicated in table 1, and the results of the gastric analyses are expressed in chart 1.

The actual diet from the combined gastric analysis and leukopenic index studies consisted of rice, apples, cauliflower, asparagus, chicken, oatmeal, beets, cabbage, sweet potatoes, coffee, pork and fish. It so happened that wheat, milk and eggs were the first foods tested and, as they were incompatible, they were taken out of the diet immediately. This initial omission was of distinct benefit, so no further restrictions were advised until the entire study was completed. Since the restriction of incompatible foods there has been absolute comfort and there has been no more trouble with constipation except after an occasional deviation from the diet. During this entire period the patient continued at his work and, of late, has been working overtime at night. One evening at a party, a well meaning hostess insisted that the patient eat some fresh angel food cake. There was acute pain in one hour which lasted most of the night and which was not relieved by food in the revised diet. Eight months later the patient added milk and potatoes to his diet of his own accord and experienced a prompt return of all symptoms. Pain disappeared in two days after milk and potatoes were again omitted, but constipation continued for ten days. The man is now perfectly comfortable, he eats three meals a day, works every day and takes no medication.

CASE 2—T. M., a man, aged 32, a liquor dealer, complained of early morning pain which would awaken him and which was relieved by food. It had been assumed that the pain was due to gas, because belching had always given partial relief. This pain had been present for about a year, but the patient had ignored it until two months before the present consultation, when he fainted while at work. On regaining consciousness he vomited a large amount of blood, fainted again, and was then taken to a hospital. On admission to the hospital all foods and fluids were restricted by mouth; a nasal tube was passed and the stomach was washed free of clots with physiologic solution of sodium chloride. An ice cap was placed on the epigastrium, 10 per cent dextrose solution was given intravenously, morphine was administered and 1 cc of parathyroid extract was given intramuscularly twice daily for two days to decrease the bleeding time. As there was no tendency to further hemorrhage, food was given gradually and in ten days the patient was allowed to return to his home. After an interval of three weeks a roentgenologic examination of the gastro intestinal tract was made and a diagnosis of duodenal ulcer was returned. During this period there had been rather more pain than usual and he had been eating soups, custards, raw and coddled eggs, bread and milk and he had been drinking a large quantity of milk.

The past history was not important except that there had always been a good deal of sneezing. There was no other history suggestive of allergy. He had been in the habit of drinking beer every day. His father died of pneumonia, his mother was living and well. The patient was married. His wife was well, she had never been pregnant.

The patient was of sthenic habitus and pale. The blood pressure was 110 systolic 70 diastolic. He weighed 51 Kg. There was no reaction when the skin was stroked. The pupils reacted to light and on accommodation. There was a slight excess of mucoid nasal discharge. The teeth were in good repair and the throat was slightly reddened. The thyroid gland was not palpable. The lungs and heart were normal. There was a point of tenderness of about 1 degree in severity in the epigastrium. All reflexes were normal.

A comparison of the skin tests and the compatible foods by the leukopenic index and by gastric analysis is noted in table 2.

and chart 2. In this case, as in case 1, wheat, milk and eggs were eliminated first and there was an immediate and complete cessation of symptoms. It will be noted that these foods were the ones used after his hemorrhage, and it was during this period that he experienced an unusual amount of pain. No other restrictions were imposed until the study was completed. The final diet consisted of cauliflower, apples, coffee, beets,

Chart 1—Fractional gastric analyses in case 1. The four charts show the response of free hydrochloric acid to foods used as test meals with coincidental leukopenic index study. Numbers refer to foods listed below the charts. The degree of leukopenia is listed opposite the incompatible food. Solid lines indicate incompatible foods, broken lines compatible foods.

string beans, cabbage, carrots, tomatoes and oatmeal. This was not a very interesting diet but it was felt that all foods giving an incompatible reaction should be restricted in order to avoid a quick sensitization to allergens that at the present time were subclinical in type. It has been observed that the regular use of these foods soon results in clinical manifestations of peptic ulcer even though the major allergens are out of the diet. The occasional use of indeterminate foods and those which do not reproduce pain except by cumulative action does not seem to be harmful.

The patient was free from pain and discomfort from Dec 17, 1934 to June 9, 1935, when he ate a sandwich while on a picnic. He had pain in about one hour which lasted for about six hours. From the time the diet was instituted until the short recurrence of pain there had been a gain in weight of 19 pounds (8.6 Kg). Two months later he again broke his diet this time eating wheat beef and a creamed soup for lunch and

repeating the same foods at his evening meal to determine whether he had acquired a tolerance for them. Two hours later he felt dizzy and experienced a severe substernal pain. The next day he passed tarry stools and the dizziness continued. He did nothing about his condition except to be more careful about his diet and a few days later he felt perfectly well again. One week later he came for his customary check

up. The hemoglobin was 82 per cent, the blood pressure was 115 systolic, 70 diastolic, and the weight was 68.5 Kg, making a total gain of 17.5 Kg in nine months. He is comfortable again and intends to avoid the major allergens in the future.

CASE 3—Mrs J V, aged 44, in August 1928 complained of pain in the right upper quadrant of the abdomen which was referred to the back and which had been present for one year. The onset had been gradual, with sensations described as indigestion occurring at irregular intervals, depending on the type of foods eaten. She usually felt well in the mornings or while at rest, as effort seemed to increase her discomfort. Since the patient felt better on a light diet, her food intake had been limited accordingly. Three weeks prior to examination there had been an attack of indigestion followed by pain in the right upper quadrant of the abdomen and by pain referred to the right side of the back. Since that time the pain had been rather constant but there were occasional periods of relief during the day. During this period there had been frequent vomiting of recently eaten foods and there had been much gas and bloating. The distention was in the lower part of the abdomen and was noticed particularly after the heavier foods. The bowels moved normally. The patient was nervous, slept poorly and had lost 10 pounds (4.5 Kg). Ten years previously the appendix and a fibroid tumor of the uterus had been removed. Her mother had suffered from gallstones and had died following cholecystectomy. Her father died of senility. The patient had been married for fifteen years and her husband, a farmer was living and well and two sons were living and well. There had been no miscarriages.

The patient was of hypersthenic habitus, and weighed 83.7 Kg. The blood pressure was 125 systolic, 70 diastolic. Nutrition was overgood and the complexion was florid. The pupils reacted to light and on accommodation. The teeth were well kept, the throat was reddened and the tonsils were enlarged. The nasal mucosa was excessively moist and grayish. The thyroid was enlarged and soft. The lungs were normal and the heart sounds were regular and clear. There was a post-operative scar in the lower midline of the abdomen and there was tenderness of 1 degree in the right upper quadrant. As a chronic cholecystitis was suspected from the history, a cholecystogram was done and the gallbladder was visualized perfectly in all films. A barium sulfate meal was then given and a grossly deformed and tender duodenal cap was demonstrated. The Sippy routine of ulcer treatment was instituted and the patient made reasonably satisfactory progress until January 1931 when signs of subclinical obstruction developed. As the patient had grown careless with her diet she was again put on liquids with alkali and atropine and gradually improved. After this experience the diet was observed more carefully and though there were exacerbations of pain from time to time there was no more serious trouble until January 1935 when the same type of pain returned, but much more severely. This pain had been coming on gradually and the patient had been vomiting at night for several months. The vomitus at times contained blood. The severe pain which had been present for about one month prior to reexamination occurred two hours after meals and at night and was relieved by vomiting. There had been no tarry stools and the bowels had moved normally except for attacks of diarrhea after the recent attacks of vomiting. There had been much gas and distention of the lower part of the abdomen. On questioning the patient remembered that her father was subject to asthma and that she herself had had attacks of asthma while a child in Switzerland. She also recalled that peaches, spinach and pastries had always caused abdominal pain and that milk butter and lard had always caused gas. The roentgenologic examination was repeated and revealed a definite pyloric obstruction that increased the emptying time of the stomach for considerably more than six hours. As a consequence, the patient was given ten injections of histidine with excellent results as the emptying time of the stomach decreased markedly. The duodenal cap could then be visualized and it exhibited the gross deformity characteristic of duodenal ulcer. Skin tests were done and the patient was asked to keep a food diary. A few foods were excluded by the diary alone while wheat, milk and potatoes were excluded by the leukopenic index. Egg proved to be a compatible food. Pain had continued after histidine but histidine had apparently relieved the accompanying ulcer edema to such an extent that

there was no longer an obstruction. The elimination of wheat, milk, potatoes and pork from the diet has made the patient perfectly comfortable. She is now eating three meals a day, takes no medication and works every day. She can eat any of the compatible foods listed in table 3 with impunity, but any of the incompatible foods cause an immediate return of pain. These foods may be her only allergens but it was thought advisable to continue the leukopenic studies even on the list compatible

by diary. The patient, however, did not think so and when asked to come in for more food studies replied: "What is ze use when all day long I seeng like ze bird."

CASE 4—H. C. C., a man, aged 43, complained of gas and bloating after certain foods which were followed by a sensation of severe pressure and severe pain. The onset had been twenty years before with pain after meals and night pain. He was told at the time that he had a duodenal ulcer. The symptoms persisted for several years until an attack of typhoid. After his recovery from typhoid it was noticed that the pain had disappeared but that severe indigestion continued. There was a severe hemorrhage from the stomach about one year after the attack of typhoid. After this experience he was treated by diet and medication with little benefit until a gastro-enterostomy was performed at one of the large clinics. After the operation there was a moderate degree of clinical improvement, but there has always been digestive discomfort of varying degrees of severity. Three years before examination another severe hemorrhage had occurred. After rest in bed and a liquid diet there was again improvement for a few months, and then another hemorrhage. As the patient was on a careful diet he merely stayed in bed until there was no more bleeding and then went on his way as usual. There had been no other illnesses or operations in the past history. There was never any fever but he had always caught cold rather easily. There was no chronic cough. Frontal headache had been frequent and troublesome. There was no personal history of allergy, but the patient's daughter had urticaria. There were some known foods that caused immediate discomfort and others that were suspected. The gastric symptoms consisted of gas and bloating for three or four hours after meals and a pressure sensation which at times became a severe pain. The greatest ease and comfort was enjoyed when there was no food in the stomach. There was rarely any nausea or vomiting. The appetite was good and the diet consisted of eggs, orange juice, coffee, milk, and malted milk soups, custards, cold meats and either baked or mashed potatoes. The bowels had always been normal. There was no weight loss and there was but little difficulty in sleeping. The father and mother both died following cerebral hemorrhages. There were two brothers living but one of them had been ill with multiple lung abscesses and was still in a serious condition. The patient's wife was in good health and his one daughter was in good health. The habits of life were regular. The patient's occupation was that of first assistant to the over-

worked and harassed head of a large corporation and, though his hours were supposed to be from 8 a. m. to 5 p. m., there was considerable night work to be done and work was always done under pressure. To add to the man's physical ailments, he had the responsibility of his brother's illness and the usual family responsibilities that are shifted to efficient men.

The patient was of hyposthenic habitus. The blood pressure was 110 systolic, 80 diastolic. He weighed 55 1/2 Kg. The nutrition was moderately good but the nail beds and mucous membranes were rather pale. There was a moderate erythematous response on stroking the skin. There was a marked areus semilis but the pupils reacted to light and on accommodation very promptly. The nostrils were clear. The teeth were well kept and in good repair. The throat was reddened. The thyroid was palpable but soft, and there was no increased vascularity. The heart and lungs were normal. There was a postoperative scar in the upper part of the abdomen. There was tenderness of 1 degree in the epigastrium and there was rather marked distention of the lower part of the abdomen with gas. All reflexes were physiologic.

On roentgenologic examination of the gastro-intestinal tract there was partial functioning of the gastro-enterostomy, stoma and deformity of the duodenal cap. Very marked reactions were obtained by skin test with asparagus, beet, cabbage, chicken, coffee, milk, oat, onion, pepper, potato, rice, sweet potato and wheat. These foods were eliminated and testing by a trial diet and by a food diary was undertaken. By diary and by clinical test it was found that all cereals with the exception of rice, were distinctly and violently antigenic. It was also proved that the repeated use of chocolate, string beans and potatoes, by cumulative action, caused discomfort in a less degree. Milk was suspected but milk as an antigen could not be proved by diary, as its action was later proved to be a slowly accumulative one. The patient cooperated in an admirable and extraordinarily intelligent way with but one deviation from his instructions. This instance occurred while out of town on a business trip and consisted of the self-administration of a cathartic containing phenolphthalein. This drug brought on a violent attack of urticaria, and during this attack, whether it was a coincidence or whether there was a similar reaction in the stomach, another hemorrhage of slight degree but accompanied by tarry stools occurred. From that time to the present, progress has been very satisfactory but it has been very difficult to increase the diet. Milk, though not proved by diary, was demonstrated as an allergen by the leukopenic index and there

has been distinct relief since its omission. As will be observed in table 4 there was a wide variation between the skin tests and the actual allergens as determined by diary and by the leukopenic index. Furthermore, the patient's personal observations have been most interesting as he is able from his diary record, to predict the outcome of his leukopenic index studies in most instances. His compatible list consists of beef, jelly, eggs, corn, plums, prunes, butter and tea, but he is able to eat rice, peas, beans, potatoes and lettuce if he does not eat any of these foods too often. That is, rice, peas, beans, potatoes and lettuce produce pain by cumulative action if they are repeated in the diet any oftener than every third day.

CASE 5—J T A, aged 45 a high school principal complained of a sensation of emptiness of the stomach and a sensation of fullness and dyspnea after meals. The trouble began with a desire to yawn, which persisted but yawning did not relieve whatever caused the urge to yawn. About four years before there developed a sensation of gnawing emptiness of the stomach when the stomach was empty which was only partially relieved by food. After meals there was a sensation of dyspnea,

which at times was severe and as a result exercise had been limited. Occasionally this dyspnea occurred a few hours after meals and then it was relieved by food. There was an attack of influenza shortly after the onset of the gastric symptoms and the symptoms had been worse since that time. The patient had been told that he had a duodenal ulcer and he received some benefit from conventional ulcer treatment. There had been no fever and no symptoms suggestive of allergy. The gastric symptoms were confined to a sensation of fullness and a moderate amount of belching. The pain was in the epigastrium and though constant, there was a moderate degree of food relief and some relief from lying down. The pain was described as an empty gnawing sensation. The diet had been composed mainly of cereals, milk and eggs as advised by his local physician. Constipation had been marked and magnesia magma had been used as a laxative. Sleeping had been difficult and there had been a slight loss of weight attributed to broken rest. The

past history consisted of a very mild attack of joint pain which was not disabling, and a tonsillectomy complicated by an abscessed throat. The patient's father died of kidney disease and his mother died of pneumonia. There was one brother and one sister, both of whom were well. The habits of life had always been regular but the patient had been getting much less exercise during the past few years than he was accustomed to having. Following an active athletic college life the coaching of football and track had been a part of his teaching duties.

The patient was of sthenic habitus. The blood pressure was 110 systolic 70 diastolic. He weighed 660 Kg. The color and nutrition were good. There was a moderate reaction when the skin was scratched. The pupils reacted to light and on accommodation. The nostrils were clear. The teeth were in good functional repair. The throat was reddened and the tonsils were absent. The thyroid was not palpable. The lungs and heart were normal. There was tenderness of 1 degree in the epigastrium. All reflexes were physiologic. The clinical impression of duodenal ulcer was confirmed by roentgen examination. Skin tests were done and beef, chicken, coffee, pork, potato, fish, condiments and corn, which reacted strongly, were eliminated from the diet. The patient was then put on a food diary in order to prove or disprove these foods as allergens. As there was but little change after an adequate test period tests by the leukopenic index were done with the results listed in table 5. In this study two errors were made. Corn was tested after a prolonged abstinence and a curve denoting compatibility with a leukocytosis of 1,600 was obtained. Corn was then replaced in the diet but produced pain consistently. The test on corn was then repeated and there was a loss of 1,000 cells in twenty minutes. Corn as a food was then discontinued. Beef caused a loss of 200 only in twenty minutes followed by hyperleukocytosis at forty, sixty and ninety minutes. The initial insignificant loss was disregarded because of the indeterminate result of the gastric analysis, and beef was allowed as a food. It proved to be a symptom producer on trial and was discarded. The present diet consists of eggs, peas, lamb, spinach, tomato, prune and rye. The patient is perfectly comfortable on this diet and is eating but three times a day. The only medication is liquid petrolatum.

CASE 6—B C G a man aged 55 complained of nausea, pain and pressure in the epigastrium, which was constant but which was partly relieved by food. The onset of the illness had occurred about fifteen years before. He had been a heavy whisky drinker but finally had to stop drinking because of nausea. This nausea was thought to be due to biliousness, and he began taking mild mercurous chloride and laxatives of his own accord. Shortly after this episode he began to be conscious of hunger pain and a pain that was referred to his back. As the patient had a yellowish color, his physician apparently thought he was suffering from cirrhosis of the liver and from gallbladder disease and an operation was advised. The patient was told that at operation the liver and gallbladder appeared to be normal but that the appendix was diseased and that it had been removed. No comment was made to the patient about the duodenum but a diet was advised, and, since he was more comfortable on this routine than on other foods, he had adhered to this original menu which was essentially a modified Sippy diet. Since the operation the patient has been roentgenographed numerous times in various cities and had had a diagnosis of duodenal ulcer made five times by different radiologists. There had been ulcer symptoms fairly constantly for fifteen years but there had also been periods of comparative comfort. Soda crackers had been kept within easy reach at night at all times as a few crackers usually relieved night pain and permitted sleep. Unwise eating or the smallest drink of liquor brought on an attack of pain that persisted for three or four weeks. Washing the stomach gave relief and gastric lavage had been practiced from one to three times a day for many years. He caught cold easily and colds hung on. Headaches were rare but there was a general aching over the body and a feeling of toxaemia. There was no evidence of allergy in the past personal history or in the history of the family. Constipation had been troublesome and there had never been an evacuation without the use of magnesia magma. There had never been any blood or mucus in the stools. The weight was 20 pounds (9 Kg.) under the usual normal. The health, other than the present condition, had always been good. The patient's mother had an ulcer of

the stomach but died following a broken hip at the age of 82. His father died in a like manner at the age of 75. There was one sister, she had a goiter which was probably colloid in type. The patient's wife was living and well and there were four daughters, living and well. The habits of life had been quite regular for the past fifteen years.

The patient was of sthenic habitus. The temperature was 98 F and the blood pressure 90 systolic, 55 diastolic. The nutrition was rather scanty. The skin had a yellowish tinge and there was a moderate scratch reaction. The pupils reacted rather sluggishly to light and on accommodation. The nostrils were clear, the teeth were in good repair and the throat appeared to be normal. The thyroid gland was not palpable. The heart and lungs were normal. The abdomen was distended with gas and there was a small localized area of muscle spasm in the right epigastrium. The liver edge was not palpable and there was no liver tenderness. There was a postoperative scar in the right rectus region and there was an inguinal hernia on the right side supported by a truss.

Wheat, milk, egg and potato were tested in the order named, and each food caused a marked loss of cells. These foods and all cereals were restricted immediately and these restric-

is at times necessary for a food to be in a diet for a week or ten days before symptoms are produced and several days of abstinence are necessary before its influence disappears.

This confusion can be overcome by the use of single food testing and the leukopenic index. A definite and sustained leukocytosis after food ingestion indicates a food which is entirely compatible and is symptom free alone or in a mixed diet. A loss of leukocytes after a single food intake indicates the reverse reaction that the food in question is an actual allergen and that it is able to reproduce symptoms. This has been demonstrated repeatedly, by accident and by purposeful feeding. It is important that a food to be tested should be included in the diet a few times during the week preceding the test. Apparently the leukocyte response becomes refractory to an occasional previously restricted food until it has been in the diet for a time. Repeated tests on a food of this type produce curves going from a sustained leukocytosis to a leukopenia that decreases with each succeeding test.

An immediate leukopenia is significant of an allergen, and leukopenia of slight degree followed by hyperleukocytosis has the same significance. The majority of major allergens used as a gastric test meal have the ability to depress, or to inhibit totally, the free hydrochloric acid secretion while compatible foods are followed by a normal response. Foods that are indeterminate by the leukopenic index may at times be properly classified by the response of free hydrochloric acid to them. The variation in acid values may be due entirely to the presence or absence of the buffer action of mucus and the secretion of a marked excess of mucus in the presence of a known and proved allergen is probably a protective mechanism similar to the allergic reactions of any other mucous surface.

It appears, then, that the pain of peptic ulcer occurs in the presence of antigenic foods and in the presence of an achylia or an acidity which is much lower than the usual normal for that individual. It also appears that a normal response of an increased secretion of hydrochloric acid indicates a compatible food and that a lowered acidity value indicates an incompatible food. It also appears that the usual method of employing test meals is at fault in that the results obtained are dependent on that individual's reaction or sensitization to that particular food, because gastro-intestinal allergy is much more frequent than is appreciated.

It should be pointed out that there is frequently a relationship between the degree of depression of leukocytes and the antigenic power of the food in question. In general, however, the more marked the leukopenia the more antigenic the food, and also the more marked the leukopenia the more the lowering of the hydrochloric acid value.

Though complete relief of peptic ulcer symptoms can be given a patient by feeding foods that are compatible by the leukopenic index, the objection may well be raised that conventional methods of treatment also give relief. The answer to that objection is that they do, but by a method of feeding repeated doses of the chief offending foods. By the regimen of rest, doses of antigen at frequent intervals and the added protection of belladonna, a state of antianaphylaxis is built up that does indeed promote a cessation of symptoms. This state of antianaphylaxis persists until its balance is disturbed by a gradually increasing diet and then symptoms are likely to recur. Not only is relief of symptoms by antianaphylaxis possible in any other type of allergy

TABLE 6—Results of Skin Tests and Leukopenic Index Studies in Case 6

tions have been all that has been necessary up to the present. No further tests have been done. The patient still experiences a moderate amount of discomfort at times but he is greatly improved and he is no longer forced to lavage his stomach to keep comfortable.

COMMENT

In the foregoing presentation, six unselected cases of peptic ulcer have been treated on the premise that peptic ulcer is an allergic manifestation.³ Patient 3 had a definite personal and family history of allergy, patient 2 had only the history of sneezing as a possibility of hypersensitive rhinitis, and patient 4 had a daughter with urticaria. There was no allergic history in the other three cases. Several points of interest have developed during the course of this study, one of them being that wheat and milk, which form the basis of usual ulcer diets, were definite allergens in every patient. Egg was an allergen in three or 50 per cent of the cases. It was also observed that skin tests are of little or no value in gastro-intestinal allergy, mainly because the clinical reactions of some of the major allergens and many of the minor ones are of the cumulative type. This finding limits the reliability of the skin test practically to minimal allergy. It follows then that food diaries can be definitely misleading. It

but an appreciation and understanding of this phenomenon is most important in properly interpreting a food diary. The important point is that a food producing a symptom is also capable of partially relieving that symptom when taken later. In other words, the pain of peptic ulcer may be due to a localized anaphylactic spasm which is relieved by antianaphylaxis or actually by the interval feeding of an antigenic substance which originally caused the spasm. This was strikingly demonstrated by case 1, in which pain developed from a food composed of wheat and egg white but relief was not possible from eating foods known to be compatible. Before the institution of a correct diet, food had always given the patient relief from ulcer pain. Expressed differently, antigenic foods relieve pain and simultaneously reduce the normal optimal gastric acidity, which is a condition approximated by the use of alkali and belladonna. A diet composed of compatible foods exclusively is capable of giving complete relief from ulcer symptoms and is capable of freeing the patient from medication, from interval feedings and from the necessity of hospitalization.

HISTORY TAKING IN ALLERGIC DISEASES

FRANCIS M. RACKEMANN, MD

Associate in Medicine Harvard Medical School Physician
Massachusetts General Hospital

BOSTON

The successful treatment of hay fever, asthma and eczema, like the successful treatment of other diseases depends on a complete understanding of the patient and his particular problem. In the allergic diseases this is especially true because, as Pirquet¹ has described, the symptoms depend on the peculiar capacity of the individual to react toward certain foreign substances. Not only must the physician understand the physiologic changes in the body of his patient, but particularly in the cases of hay fever, asthma, eczema and the other manifestations of allergy he must understand the patient's environment, his contacts with the various foreign substances that it may contain, and his reaction to these contacts. Recent clinical experience has led to the use of certain "tricks" in history taking in allergic diseases which are of such practical importance that their recognition constitutes a virtual advance in diagnosis and treatment.

First of all the physician must know whether or not the symptoms of which his patient complains are probably of allergic origin. Elsewhere I² have laid stress on the five criteria of allergy—those symptoms and signs which are characteristic of each manifestation of clinical allergy and which when found, are helpful to the diagnosis. These criteria are: 1. A characteristic symptom dependent on a characteristic local pathologic condition. 2. The presence of some other allergic symptom in addition to the first. 3. A positive family history of allergy. 4. Positive skin tests. 5. A blood eosinophilia. Obviously, the physician cannot give proper treatment until he can determine that his patient has hay fever and not sinusitis, or that he has asthma which depends on allergy and not on heart disease or tuberculosis, or perhaps a wheezy bronchitis.

Eczema is easily confused with various fungous infections of the skin, urticaria with scabies, migraine with many varieties of headache, and so on. Differential diagnosis is always important, and the diagnosis, which the patient himself often assumes, must not be taken for granted. It is not my purpose in this paper to discuss the details of differential diagnosis but it is necessary to point out that they exist and may be easily overlooked.

Furthermore, any of the allergic diseases may coexist with and be complicated by some other disease. Even if the patient does have asthma, for example, it is still necessary to make sure that he does not also have organic disease of the heart or lung or even a tracheal obstruction of which his so-called asthma is merely the presenting symptom.

Meantime, the allergic diseases are common (text books say that from 1 to 4 per cent of the population is afflicted) but "cures" are not so common. "Cures" of the allergic symptoms (though not of the underlying allergy) result whenever the particular substance or substances can be found and eliminated—the family cat, the feather pillow or the floss mattress, for example, or whenever the patient moves away from it or them. This happens more often in the textbooks than in actual practice. The physician must realize that the dramatic relief of symptoms frequently described as the result of a happy finding in the typical "textbook" cases occurs in only a small proportion of the whole number of patients. These cases are almost in a class by themselves. Always, however, there is hope that the next case will belong to this typical group and that the cause of trouble will be as easy to find here as in the other "textbook" cases. Furthermore, there is always hope—and justifiable hope—that the typical "textbook" group will be extended by new knowledge into many directions to embrace an ever greater proportion of allergic patients.

Since the fundamental nature of allergy, of the capacity to develop sensitiveness and then to react to the specific substance, is still unknown, present interest, at least from the practical point of view, concerns the exciting cause of the symptoms.

Diagnosis of the exciting cause of asthma, sometimes referred to as the "trigger" mechanism, rests on three factors, which in the order of their importance are the history, the physical examination and the skin tests. At first it was thought that the skin tests were infallible, that when a patient showed a positive reaction to some substance, that substance was of great clinical importance, and that when the patient did not react the corresponding substance was of no importance. This simple point of view cannot now be maintained, because it is recognized that the skin tests are fallible in two directions. First, positive skin tests can occur with no clinical symptoms to go with them. The point is easy to prove because the discrepancy can be found in many patients. A good example is the patient who has hay fever which does not begin until August, he has no trouble in June, and yet his skin tests to the grass pollens are quite as large as his skin test to ragweed. Obviously, the positive grass tests have no clinical significance. This particular discrepancy between tests and symptoms is a common one. Positive skin tests to animal danders, to wheat and to other allergens, with no evidence of clinical sensitiveness to go with them are also common. The skin tests are fallible in the opposite direction also. Clinical sensitiveness can occur even though the skin tests are entirely negative and by

¹ Pirquet Clemens. *Allergie*. Munchen med. Wchn. chr. 53: 1457 1906.

² Rackemann F. M. *Clinical Allergy, Particularly Asthma and Hay Fever*. New York: Macmillan Company 1931.

every method. This discrepancy is not so easy to demonstrate. However, there are a few type cases that seem to prove the point. In one, for example, the asthma cleared entirely when the cat was sent away, but skin tests to cat hair remain negative. A more objective finding is that of Franklin Stevens,³ who found that, if the specific substance was applied to the bronchial mucosa through the bronchoscope, asthma would result even when the same substance caused no reaction by skin test. If these two fallibilities are true, it is quite apparent that the skin tests lose much of their glamour. Results from skin tests must still, as always, be interpreted in terms of the history.

Physical examination is always important. Wheezing is asthma, but the type of asthma, the presence of secondary infections, the presence of focal infections and the presence of other lesions are all to be determined by physical examination, which must never be neglected or overlooked.

It is the history, however, which, from the practical point of view, becomes the chief diagnostic measure. The patient's age, his heredity, his previous medical experiences and his general makeup are all important. His mental capacity and reactions should be noted. Are his statements reliable? Does he probably exaggerate or, on the other hand, does he make light of symptoms which are severe and possibly serious? Are there emotional loads, financial difficulties and the like, which in themselves could aggravate symptoms of any kind and origin, to make a bad matter worse, and thus confuse the primary cause of trouble?

The family history may be important because the tendency to hypersensitivity—the "allergic state"—is often inherited. "Does any one in your family have hay fever or asthma or skin trouble (eczema) or perhaps migraine?" is a useful question. In 1916 Cooke and VanderVeer⁴ studied two series of families and found that if one parent was allergic 60 per cent of the children showed some manifestation of allergy, whereas if both parents were allergic the figure was higher, at 67.5 per cent. According to the Mendelian law, the figures should be 50 and 75 per cent. If the family history is positive the fact is a little evidence that the patient's symptoms are of allergic origin.

The important part of the history concerns the environment and particularly the changes in environment and whether or not these changes were accompanied by corresponding changes in symptoms. To understand the patient's occupation past and present, its hazards and particularly the dusts connected with it, may lead to the easy discovery of the cause of trouble. The residence is important. Farm houses have dusts from animals, hay, grain fertilizers and insecticides which may be quite different from the dusts of the city. Inside the house, however, the problem becomes even more complex, as will be discussed presently.

But how can the doctor discover which of the many possible sources of trouble is the real one or ones? The 'tricks' that were mentioned in the opening paragraph will help to answer this question. It is the changes in occupation, in residence, in furniture or in other factors, which must be studied carefully.

The first 'trick' is to record dates. Hay fever comes and goes according to the dates on which certain pollens to which the patient is sensitive are in the air. Asthma

that comes in short sharp attacks "twice a year" is better understood when the dates are included and one learns that these dates were October and March "the open season for head colds." A school boy had attacks three times a year, "eleven months ago, seven months ago, and five months ago" a meaningless story until the dates were recorded and it was appreciated that December 21, March 28 and June 12 represented the beginnings of vacation and the change from boarding school to home (where there was a cat!). A woman had asthma "about five times last winter." The first impression was that these attacks came about a month apart, but questions about dates brought out the fact that the five attacks had followed one another in quick succession and that they all occurred in the month of December, at a time when she went on a long visit to her grandmother in New Jersey. Through the rest of the winter she was free. Some time ago a student, taking a routine history, described at great length an attack that occurred "seventeen months ago" and then another attack which occurred 'five months ago.' Whether he himself knew the dates is doubtful. At any rate the poor fellow had made an actual effort to exclude the fact that the difference between seventeen and five was twelve, that the two attacks were exactly a year apart, and that both of them had occurred in the month of September, which, of course, was quite enough in itself to suggest ragweed as a precipitating cause. Subsequently, this was proved to be the case—a diagnosis made on one crucial point—the dates in the history. "On and off" as a careless estimate of the number and frequency of attacks won't do. The lazy questioner will miss the point.

Dates by months are usually accurate, but the patient may know the exact day. 'Seven years ago' becomes only 'five years ago' when the date of the attack is correlated with the known date of a certain operation.

About six months ago" turns out to be not March but May, or at any rate at some time after the grass had begun to turn green. Actually it was only four months ago. As usual, the patient had exaggerated unconsciously. Dates are not hard to remember because they can usually be checked with other circumstances, birth-days, school graduation, the weather, snow on the ground or leaves falling. Changes in residence, child-births, operations and accidents provide further clues to exact dates.

An incidental point about dates refers to the study of old records. To read "fifteen months ago" on a history taken in February 1927 requires some mental arithmetic to find that the event took place in October 1925, and the process involves two possible errors: first, the original calculation of 'fifteen months ago' and second, the subsequent reduction backward to the date. In case, however, dates are used, one can read that the patient was well until October 1925 (with his age of 42 in brackets)" and that 'after this attack he did well until

February 1927"—this date to begin a new paragraph, and then perhaps other dates and other new paragraphs, until finally we come to what is the present illness.

Saturday, November 23, 1935, at a football game"—and then shortly after that

Nov. 25, 1935 (age 52), admitted to the hospital with these complaints.

Such an arrangement is easy to follow and if the dates at the beginning of each paragraph are underlined a summary is provided automatically.

A second 'trick' in history taking is to account for all the time. The young woman's asthma began in

3. Steven F. A. A Comparison of Pulmonary and Dermal Sensitivity to Inhaled Substances. *J. Allergy*, 5: 285 (March) 1934.
4. Cooke R. A. and VanderVeer, Albert. Human Sensitization I. *Immunol.* 2: 101 (June) 1916.

October 1925 and was persistent until March 1926, but then came an interval of two years when she had no further asthma. Why was this? The explanation of the free period is often quite as important as is the explanation of the attack itself, and, sure enough, it was found in this instance that the patient was brought up on a farm, went away to work, and was perfectly well while living in the city. Later she married and shortly afterward asthma began again, presumably because of another change in her environment and the consequent exposure to dusts, which were evidently similar to the dusts on the old farm.

Changes in residence, and the effect on the asthma, or the lack of effect, often provide the essential clue. When vacations, business trips or pleasure trips are accompanied by a considerable relief or a disappearance of the asthma, the fact is strong evidence that by going away the patient has been able to escape from a dust that was causing trouble at home. Formal moves to a new residence are of less importance because the cat or dog, as well as most of the furniture, usually move at the same time. Hospital admissions are especially important. Not only does the patient escape from his home, but he lands in an environment in which experience shows that almost all the extrinsic cases become asthma free in a period of five days. The dates of every change in environment—the beginning and also the end of vacations—should be incorporated in their chronological order in the history. "Last August on a five days motor trip, the patient was much improved" and now in the hospital he is again free from asthma. Such a clear cut relationship between asthma and environment revealed by the history throws a strong light on the cause of the trouble.

Changes in occupation may be quite as important as changes in residence. Bakers, cooks, grain dealers, barbers, textile workers and leather workers as well as hostlers, furriers, dog and cat fanciers and those who handle rabbits, guinea-pigs, rats and mice in scientific laboratories may become sensitive to the dusts in their occupational environment. The dates in the history should show when the occupation began and when it was interrupted. Here is a barber sensitive toorris powder and with strongly positive skin tests. The diagnosis appears easy until it is known that he has not worked in the barber shop for six months or more and yet his asthma continues. On the other hand, Peter R. has asthma only when he makes lobster salad in the kitchen of a big hotel.

When the patient has lived always at home with no vacations or travels and no change in occupation, a study of the history is more difficult chiefly because of the absence of history. Under these conditions the asthma has usually been persistent from month to month and week to week. In such a case the diagnosis is difficult unless additional methods of study are employed. These are not concerned with history taking so much as with the care of the patient, but nevertheless they often play an important part in the making of the diagnosis and it is therefore proper to consider them here. The procedures could be called "making history." Their nature will become apparent when the new experiences regarding environment and its various factors are explained.

"Allergic cleanliness" is a significant expression, first used by my associate Dr. Colmes. "Allergic cleanliness" indicates the elimination of those dusts likely to cause trouble in the patient's environment. Any live animal may cause trouble. The removal, however, will

not do good unless it is remembered that animal dusts may remain adherent to sofa pillows, rugs, blankets, riding breeches and similar items. Grandma's cat and its hairs "all over the house" is an excellent example. A college boy had asthma only on the days when his roommate rode horseback. Cotton, kapok and feathers, as the common stuffings of modern furniture, may each or all be exciting causes of asthma. "House dust" becomes interesting from several points of view.

There are several methods of study. First, the patient can be moved away from home for a trial period of observation. Almost every one has relatives or friends who can take him in to live with them for a trial period of a week or two, to see how the change in environment will affect the asthma. Better still, the patient can enter the hospital, where the treatment will consist chiefly of living in the hospital with its linoleum floors, painted walls, sterilized hair mattress, clean bedding, absence of animals and general freedom from household dusts. An analysis of seventy-five extrinsic cases⁵ admitted to the wards of the Massachusetts General Hospital showed that all but two of the patients in this group lost all their symptoms within a period of five days.

Secondly small samples pulled out from the stuffing of chairs, sofas, mattresses and pillows are often helpful, when their significance is understood.

Cotton may be harmful at times especially if it is dusty and dirty, and full of whole or broken seeds.

Kapok ("silk floss") is poor stuff. Its fibers are small and soft, but soon they become dry and brittle and break down into a fine dust, which escapes through the casing in quantity. The bedding along the mattress edge will be full of it. Kapok pillows lose so much of this dust that they lose weight rapidly and become lumpy. Soggy, flabby kapok pillows can be recognized across the room. They cause asthma often. Kapok that is fresh and new is not harmful, for the fibers are intact. New kapok pillows may bring relief to asthma. Soon, however, in a few months, the disintegration starts. In a recent study, Wagner and I⁶ have found that the alcohol precipitate of a water extract of new kapok contains 0.06 mg. of total solids and little if any nitrogen, whereas a similar precipitate of kapok dust using aliquot quantities contains 0.3 mg. of solids and 0.004 mg. of nitrogen. This finding is quite in line with the previous work of Milton B. Cohen,⁷ who found a similar and marked difference in chemical constitution as well as in skin test activity between new and old cotton linters. The cause of this breakdown in vegetable fibers is of considerable practical importance and is under investigation now.

Fibers of animal origin—hair, wool and silk—are much more resistant and stable. No doubt this is the reason why they seldom cause asthma. Horsehair that has been washed and curled is in my experience, always safe and satisfactory. Patients with horse asthma can sleep on horsehair mattresses without symptoms. Evidently, the washing and curling processes have removed all the dander.

A study of the samples of furniture stuffing may indicate at once which articles should be eliminated and which other articles are probably safe. To find that the pillow or mattress is stuffed with old, broken down kapok may be all that is necessary for diagnosis and treatment. The list of patients relieved by the eliminat-

tion of such old kapok from their bedding is already considerable. A doctor came home tired each night. After supper he sat in a certain green plush chair and soon began to wheeze. History showed that in case he was called out again or in case he sat in another room that night he did not wheeze. Samples showed that the chair was stuffed with cotton which was old and dusty. The chair was eliminated and his asthma has been immensely better since then. He is not 'cured' however because he is also sensitive to dogs both by skin tests and by clinical experience and although he has no dog in his own house he meets dogs in other places. He is under treatment with dog hair extract.

The samples can be used in another way. If each is placed in a test tube and then a small quantity of Coca s fluid or other slightly alkaline salt solution is added and stirred for a few minutes, the resulting few drops of crude extract can be used directly for skin tests. A drop taken out with an applicator is placed on the arm and then a small scratch is made through it. Extracts of several different substances should be made and tested at the same time so as to compare them one with another and demonstrate that the skin is not reactive to "everything". Often a positive reaction with wheal and erythema will be seen to develop in about fifteen minutes around one of the tests. Such a reaction does not necessarily prove that the corresponding substance was the precise cause of asthma but at least the reaction is reassuring. Proof comes only by showing that the asthma goes when the article is eliminated and comes back when it is returned. Clinical experiments are more reliable than skin tests. 'The proof of the pudding is the eating.'

Thirdly, the practice of visiting the patient's home is always worth while and often essential. Mrs F had asthma of severe persistent type unrelieved by any treatment. On admission to the hospital she became well promptly and at a convalescent home this improvement continued until she fairly 'blossomed'. Back in the old flat, asthma returned the first night. Her flat was visited and it was discovered that she and her husband had five children but only three beds all of them stuffed with cotton or kapok mattresses and pillows. Mr F came home tired and slept in a small side room by himself. Mrs F was in the middle of a large double bed with kapok mattress sitting up most of the night, gasping for breath with a child asleep on each side of her. The other bed was also double size and the three other children slept crossways on it. The situation looked pretty hopeless. However it was arranged that Mr F should take his turn at sleeping with the children so that Mrs F could have the single room. This room was thoroughly cleaned with soap and water, the mattress was discarded entirely and a fairy godmother was glad to provide a new hair mattress. Since then Mrs F has been free from asthma and this in spite of the fact that Mr F has now lost his job and money for food is even less than before. Anxiety and worry among other nervous factors can be excluded so far as the asthma in the case of Mrs F is concerned.

In the case of Joe P. aged 6 a visit to the home showed that the boy with asthma was sleeping on a kapok mattress while sister Mary age 4 had a hair mattress. Since the children have exchanged rooms and mattresses Joe's asthma is greatly improved.

In the case of Mr T the history showed that the trouble at home might well depend on a new parlor set. The onset had coincided tolerably well with the

purchase of a new sofa and the two chairs and in the hospital Mr T had become free from asthma promptly. The new sofa and the two overstuffed chairs were therefore put in an upper room and the door was kept closed. Since then Mr T has had no more asthma. He has gained 40 pounds (18 Kg) and has gone back to his job. The clue to his successful treatment was in recognizing the close relation between his asthma and his environment. It paid to make history by sending him to the hospital as a test of possible dust factors at home.

ECZEMA

The suggestions that have been given apply to asthma and they apply to eczema as well particularly to that type of eczema called atopic dermatitis which is often associated with asthma or hay fever in the same individual which goes with a positive family history of allergy and which often has positive skin tests of the immediate type. The distribution of the lesions to face and neck and to the antecubital and popliteal spaces is very characteristic of this type of eczema. The condition is common. The exciting cause reaches the skin through the blood stream 'from underneath' in contrast to the group of contact dermatitis in which the cause reaches the skin directly from on top.

Foods cause atopic dermatitis but dusts also can cause it and therefore like asthma this type of eczema may vary with the environment. Eczema often clears in a hospital. A college student developed eczema in October 1934 which was bad enough to drive him home in November. At home he had treatment with X-rays and his skin cleared. In January back at college—more eczema—home again—more X-rays and recovery again until he returned to college. In June more X-rays and with greater success because he was free all summer. October however eczema came again. Every one was interested in the roentgen treatment no one was interested in the simple fact that in college he had eczema and out of college there was no eczema. Soon it was found that he had a couch or day bed and several pillows all of doubtful origin that he also wore a certain coat in college and not elsewhere. These things have now been eliminated and the eczema is very much improved. Roentgen treatment is quite unnecessary. When first seen by his doctor there was not enough history to make a proper diagnosis. Now of course it is easy to look back a year and see how unfortunate it was that when he first went home more time was not given for the change in environment to assert itself—more time for more history. Subsequent events have demonstrated that success in the diagnosis and the treatment of his eczema depended on nothing more complex than his clinical history.

The methods of Sherlock Holmes are needed in eczema as in asthma and they begin with the history and its dates.

SUMMARY

1 The clinical history is of primary importance in the diagnosis and treatment of the allergic diseases.
2 Dates in the history are not only the accurate expression of time but are essential to the successful study of hay fever of asthma and of eczema.

3 To account for all the time is to learn in many cases not only why the attack began but why it ended and then later why the free period in turn ended.

4 When the history is not long, or contains only a few events further history can be made.

5 In atopic dermatitis (eczema) the history may be quite as important as it is in asthma.

RUPTURE OF THE KIDNEY FOLLOWING PYELOGRAPHY

LOUIS H. BARETZ, M.D.
BROOKLYN

Rupture of the kidney following external violence, spontaneous rupture of a pathologic kidney and rupture of the ureter after instrumentation have been frequently described in the literature, but there is a paucity of reports on postpyelographic rupture.

It is indeed amazing that with the morbidity produced in the early pyelographic days more cases were not reported. It is possible that the condition was undiagnosed, or perhaps there was a hesitancy on the part of the cystoscopist to report such unfortunate occurrences.

Hunner¹ reported twenty-one ruptured ureters in 2,000 catheterizations. Henline² described several cases of rupture of the ureter following instrumentation (ureteral catheter, bougie and other procedures). He

Fig. 1 (case 1)—Extensive extravasation following pyelography

brought out the interesting fact that perforation of the normal ureter is difficult, in all his cases the ureter was diseased or associated with a pathologic condition such as calculus.

Similar cases were reported by Sargent,³ Noble⁴ and Geisinger.⁵ Most of these cases of perforation of the ureter followed instrumentation and not overdistention with ureterographic mediums.

Pyelographic reactions for many years were so frequent that a cystoscopy and pyelography were considered a hospital procedure. Keyes and Mohan⁶ in 1915 described the pathologic changes produced in kidneys by the then popular but extremely irritating mediums.

PYELOVENOUS BACKFLOW

With the discovery by Lee-Brown,⁷ Hinman,⁸ Fuchs⁹ and others¹⁰ of pyelovenous backflow, considerable light has been thrown on the subject. Studies were made on intrapelvic pressure and the hydromechanics of the pyelovenous phenomenon to the extent that today pyelographic accidents occur much less frequently. If proper precautions are taken, such accidents should even be rare.

Solutions such as collargol, thorium nitrate, and even the supposedly innocuous sodium iodide of recent years, have been almost entirely discarded. Pyelographic reactions following the use of these solutions have varied from a mild rise of temperature to severe fulminating sepsis, at times necessitating nephrectomy, even in the best of hands.

With the advent of skiodan, hippuran and similar organically bound iodine products used intravenously, these solutions have been put to use for retrograde pyelography with absence of toxicity and without reaction. Bilateral pyelograms with these solutions have been repeatedly used without ill effects, there is comparatively complete absence of pain.

The practical application of a knowledge of pyelovenous backflow lies in the following: Overdistention of the pelvis by pyelographic mediums will cause intrarenal extravasation, throwing into the venous circulation not only the medium but also pus, blood and micro-organisms in infected cases. Hence the rise of temperature occasionally following pyelography, hence the occasional fulminating illness, sepsis and death.

In spite of the comparative safety of the newer solutions, rupture of the kidney is a complication fraught with danger.

PREVENTION OF RUPTURE

The normal capacity of the renal pelvis is from 4 to 6 cc. An increase over this amount denotes pyelectasis, and injection of the pyelographic medium must proceed with caution. If a manometer is used, pressure should not exceed 30 mm. of mercury. If not, observation of the patient's symptoms should be carefully noted. At the first sign of an ache in the renal area, the flow must be interrupted. To determine the capacity of the pelvis aspiration should be a routine procedure. The operator can then, with a fair degree of accuracy, determine the maximum quantity of fluid to be injected.

It is particularly necessary to use caution in badly infected kidneys. Just as in perforation of the ureter, the diseased kidney is more prone to rupture. The mucosa of the pelvis and the walls of the venules and collecting tubules, in the presence of infection, have undergone anatomic changes, making rupture more than a possibility. Pyelography in the presence of an acute or subacute infection should be avoided if possible, and the kidneys visualized by the excretory method.

SIGNS AND SYMPTOMS OF RUPTURE

Pain is a constant symptom, this may be localized or general. Nausea, vomiting, fever, chills and elevation of the pulse are commonly observed. There may be a diminished output of urine with the appearance of a mass in the renal area. Rigidity or abdominal disten-

tion are later signs. Tenderness over the kidney is always present. All symptoms and signs will vary with the extent of the rupture.

The diagnosis is easily made on examination of the pyelogram. The extravasation may be extensive or localized to a small area perinephrically.

TREATMENT

When the tear is small and resultant leakage is moderate the amount of extravasation is slight the tissue reaction is prompt and the tear heals quickly. Symptomatology will accordingly be less severe, and there is less danger of a perinephric complication.

Should the clinical course show no improvement, or should there be a steady increase in signs and symptoms surgery is indicated for incision and drainage of the perinephric collection.

When the rupture is severe and there is extensive extravasation, the condition calls for immediate surgery. Depending on the condition of the patient and on the pathologic changes discovered the procedure will vary.

The left catheter was kept in situ and a left pyelogram was done, 35 cc of skiodan being used. It showed a marked enlargement of the left kidney. The contours were not very clearly demonstrated however. There was a large opaque calculus in the upper pole of the left kidney about 1¼ inches (3.2 cm) in diameter. The pelvis and calices were incompletely filled and were very distorted. These changes were the result of a large calculus in the left kidney with associated hydronephrosis.

The urea nitrogen was 160 mg per hundred cubic centimeters creatinine 176, and sugar 355. The urine was negative for sugar but showed many pus cells. Urine from the left kidney yielded pus and *Staphylococcus albus*, from the right kidney an occasional white blood cell.

The left kidney catheter remained in situ for two days and drained well. Then it slipped out of position. The patient still appeared to be too ill for surgery such as a contemplated left nephrostomy. Cystoscopy was repeated and the indwelling left ureteral catheter was reinserted. At this time it was noted that there was a fair return of indigo carmine from the right side in twenty minutes but none from the left.

The left pyelogram was now repeated, 75 cc of skiodan being used.

Fig 2 (case 2)—Appearance before pyelography

Fig 3 (case 2)—Appearance of normal pyelogram

Fig 4 (case 2)—Extravasation through the superior calyx following pyelography

Amply drainage alone, nephrostomy or nephrectomy must be considered.

REPORT OF CASES

The following three reports of rupture are illustrative.

CASE 1—Mrs. Mary O., aged 63, admitted to the Kings County Hospital May 4, 1934, in the department of genito-urinary surgery in the service of Dr. F. L. Senger, had fallen on her abdomen four months before while carrying a heavy weight and had had abdominal pain since. One week before admission this became severe, necessitating hospitalization. Pain was particularly severe in the left lower quadrant and left lumbar region. There was no vomiting and no urinary symptoms were present.

On examination the patient was acutely ill with a temperature of 102 F and a white blood cell count of 32,000 with 85 per cent polymorphonuclear leukocytes. The abdomen showed a mass extending from the left upper quadrant to the iliac crest, moderately tender and apparently renal. There was exquisite left costovertebral tenderness.

Cystoscopy revealed a hazy bladder urine and a moderate generalized cystitis. The indigo carmine test intravenously showed no dye from either side after fifteen minutes. Bilateral catheterization showed no definite obstruction on either side. From the right, clear urine was obtained, from the left toothpaste pus.

That night the patient became weak and listless. The pulse was only fair. Drainage from the catheter was scant and bloody.

The pyelogram revealed that after injection of the fluid a large amount was noted above and slightly below the iliac crest. A large part was in markedly dilated calices and a considerable amount appeared to be extrarenal. There was marked dilatation of the ureter, which ended abruptly at the lower sacro-iliac level (fig. 1).

Operation was performed immediately. A lumbar incision was made in the usual manner, a stab wound was made in the large renal mass yielding 500 cc of foul smelling bloody and purulent fluid. A nephrostomy tube was rapidly inserted. The patient's condition was precarious and no attempt was made to explore or manipulate further. Death followed shortly afterward.

At autopsy the following changes were related to the left kidney. A large amount of dirty green fluid with a foul odor was removed from within, around the kidney toward the external surface was seen an area of old hemorrhage which adhered to what was left of the renal capsule. The entire perinephric structure appeared to be necrotic and little architecture of the kidney remained. There was foul smelling pus in the pelvis. A stone the size of a walnut was found in the pelvis. There was necrosis of the entire parenchyma. The ureter was not identified, owing to the great distortion caused by the necrotic process.

The right kidney showed cloudy swelling. There was early bronchopneumonia of the right lower lobe and a septic spleen. The cause of death was perinephric abscess, sepsis and bronchopneumonia.

This was a case of calculus in a tremendous pyonephrotic sac. Visualization by a retrograde pyelogram with 35 cc of skiodin failed to fill the kidney but was definitely sufficient to establish the diagnosis. Further pyelography was contraindicated and the amount injected was entirely excessive.

Fig 5 (case 3)—Intravenous pyelogram showing evidences of right renal infection.

In May 1935 an appendectomy had been performed at the Knickerbocker Hospital but the symptoms recurred. The menses were irregular and painful.

Physical examination revealed moderate tenderness in both upper quadrants. No masses were palpable. There was slight tenderness in both costovertebral angles. There was moderate right abdominal tenderness but no spasticity. Rectal examination was negative. The temperature was normal, the blood chemistry was negative and the blood count was normal.

The bladder was normal, with normal function on each side with no obstruction to either kidney. August 6 the urine was normal. Roentgenograms and bilateral pyelograms were negative (figs 2 and 3).

The diagnosis at this time was Negative urologically. Psychoneurosis.

Following cystoscopic study there was a reactionary rise in temperature to 104 F which did not subside for eleven days. Associated therewith the patient had persistent generalized abdominal pains, particularly on the right with occasional chill. There was tenderness present in the right costovertebral angle.

The Wassermann reaction was negative and a roentgenogram of the chest was negative.

A small shadow of the gallbladder was seen after administration of the dye indicating abnormal physiology of the biliary system with or without stones.

The barium sulfate enema study was negative.

Urinalysis was done August 12. Albumin was 3 plus and there were from 25 to 30 white blood cells per high power field. Examination of the blood showed 3,850,000 red blood cells with hemoglobin 67 per cent. White blood cells at this time numbered 18,600 with 86 per cent polymorphonuclear leukocytes.

September 2 the temperature was still low grade. The impression was that there was a pathologic condition of the gallbladder and the patient was accepted by the surgical service. September 6 there was no clinical evidence of a disorder of the gallbladder and on the 11th the pain localized to the right flank near the costovertebral angle without radiation. There was no pain in the right upper quadrant. The patient was referred back to the urology service.

September 12 cystoscopy was repeated. There was turbid urine from the right kidney and clear urine from the left.

The kidney functions were good. A number 7 catheter was left in the right kidney following right pyelography.

It was now thought that the condition was right pyelonephritis (subsiding).

The pyelogram revealed a pyelovenous backflow with enlargement and marked irregularity of the superior calyx, suggesting extravasation or abscess. The left side was normal (fig 4).

The evening of the cystoscopy the patient became extremely ill. The temperature was 103 F. On September 16 the condition was worse with chills, high fever, severe tenderness over the kidney and apparent sepsis.

At operation, September 17 the right kidney was adherent to the deep fascia and was not delivered. There was a definite abscess enveloping the upper pole incision into which yielded a large amount of yellow green pus. The abscess communicated with the upper calyx. Ample drainage was established.

The patient made an uneventful recovery. The temperature subsided in from four to five days.

This case is illustrative of the evident dangers of pyelography, in the presence of acute or subacute renal infection. The diagnosis was definitely established of a subacute right pyelonephritis. Visualization, if essential, could have been accomplished by the intravenous route.

CASE 3—E. C., a man aged 32, admitted to the Jewish Hospital in the urologic service of Dr. Paul Aschner, Feb. 18, 1935, complained of pain over the right lumbar region of two weeks' duration, blood and pus in the urine, and fever. Five years before he had had right renal colic and, following a cystoscopy, voided a small stone.

The Murphy sign was positive on the right side of the abdomen with moderate tenderness in the right upper quadrant.

The temperature was from 102 to 104 F with an associated rise in the white count. Blood chemistry and the Wassermann reaction were negative.

Cystoscopy, February 19, showed a congested and edematous right ureter orifice (which may have been the result of a recent cystoscopy performed before admission). The indigo carmine test was normal on the left but there was no return from the right in fifteen minutes. A number 6 catheter easily passed obstructions at 2 and at 25 cm up the right ureter. There was a gush of purulent urine from the right pelvis with a steady hydro-nephrotic drip. The catheter was left in situ and the temperature dropped to normal in two days.

On February 21 a roentgenogram and retrograde pyelogram were done. 20 cc of skiodin being used. No shadows suggestive of calculus were seen. The right renal pelvis was considerably dilated; there was an irregularity or fuzziness of the calices suggestive of intrarenal extravasation or tuberculosis.

Fig 6 (case 3)—Extravasation at uretero-pelvic junction following pyelography.

Following this, the temperature rose again to 102 F, the catheter failed to drain properly and a second cystoscopy was done to reinsert the right ureteral catheter, February 27. The temperature then declined to normal and the catheter was removed March 3.

March 9 an intravenous pyelogram revealed a normal left kidney. On the right there was a marked hydronephrosis with blunted calices. The irregularity was somewhat bizarre in appearance, possibly because of inspissated pus (fig 5).

The urine was negative for tubercle bacilli on several examinations. The right kidney urine showed *Staphylococcus albus*. The phenolsulfonphthalein test, February 25, returned 39 per cent.

On March 12 the temperature was normal and the patient felt well.

A cystoscopy and retrograde right pyelography was performed at this time, 40 cc of skiodin being used. This study revealed (1) hydronephrosis and (2) a rather large dense shadow slightly inferior to the right renal pelvis, which was suggestive of a small sinus tract or cavity filled with the dye which may have been due to perforation of the kidney or renal pelvis (fig. 6).

For three days following this there was a rise of temperature to 101 F and thereafter a low grade temperature daily.

The diagnosis was infected right hydronephrosis with right pelvic extravasation.

Accordingly operation was performed on March 16. The kidney was found to be twice normal size. There was a marked perinephritis with marked inflammation and edema of the periureteral and peripelvic tissues, incision into which yielded about 1 ounce (30 cc.) of pus. The upper ureter was exposed and incised about 5 cm. below the ureteropelvic junction. A number 8 ureteral catheter was passed into the pelvis through this incision and fastened in situ. The kidney was decapsulated, revealing a few small cortical abscesses. Ample drainage was provided.

April 3 the patient felt well and was out of bed with a normal temperature. A cystoscopy showed a fair indigo carmine return from the affected kidney and the hydronephrotic drip was less marked (15 cc. being obtained on aspiration). The phenolsulfonphthalein test, April 7 was 52 per cent.

The patient was discharged April 7 and was to receive further dilations and pelvic lavage on the outside.

This case pertinently reveals the extreme danger of pyelography in the presence of a subsiding pelvic infection.

SUMMARY

- 1 The capacity of the renal pelvis must not be exceeded in pyelographic injection.
 - 2 Aspiration of the pelvis should be a routine procedure to determine the capacity.
 - 3 To perform pyelography on badly infected kidneys is a dangerous procedure.
 - 4 Whenever possible in the presence of infection acute or subacute, the pelvis should be visualized by the excretory route.
 - 5 If the retrograde method is essential great care must be used. If there is no apparent pain or discomfort after from 15 to 20 cc. the operator should cease and visualize the pyelogram before attempting an injection of a larger quantity of the medium.
 - 6 Surgery is usually indicated when the urography shows extensive extravasation.
 - 7 In three cases ruptured kidney followed the indiscreet use of the pyelogram.

THE ANTERIOR PITUITARY-LIKE HORMONE

A CLINICAL STUDY OF ITS EFFECTS IN
ACNE VULGARIS

CHARLES H. LAWRENCE, M.D.

BOSTON

In a previous paper¹ a preliminary report concerning the effect of pregnancy urine extract on acne vulgaris was made. This paper comprises a further study of that problem.

A review of the literature brings to light several theories regarding the cause of acne but little clinical or experimental evidence in support of them. Constipation, improper diet, lack of exercise and the normal aversion of youth to soap and water are all mentioned in the older textbooks² as probable causes of the condition, but no convincing evidence of their responsibility

Fig. 1—Biopsy specimen of skin from patient A. S. before treatment under low power. There is marked hyperplasia of the epidermis at A. Higher magnification shows many mitotic figures in that area.

for it is to be found. Later the microbacillus of Sabouraud was regarded as the specific etiologic factor in the disease until evidence accumulated that 'it may be found in myriads in the sebaceous material expressed from the follicles of the nose of practically all adolescents and adults'.³ Schramberg⁴ suggests that it may be merely a saprophyte under ordinary conditions and becomes noxious only in a soil prepared by other factors, and he points out that *staphylococcus* is present in all acne pustules yet is certainly not the cause of acne.

From the Medical Department, New England Medical Center.
Read before the American Clinical and Climatological Association, Oct. 21, 1935.

The author is indebted to Dr. Rudolf O. Good for his help and opinion in the study of the biopsy specimens.

The Time Food Remains in Stomach—The length of time spent by food in the stomach depends in part upon the proportions of carbohydrate, protein and fat eaten. In experiments where each is eaten separately, protein food stays longer in the stomach than carbohydrate, fat longer than protein and mixtures of fat and protein longest of all. In a mixed diet then the greater the proportion of fat the longer the food stays in the stomach. This action of fat may be either disadvantageous or advantageous according to circumstances. Excessive fat may retard digestion unduly and lead to discomfort on the other hand too little fat may result in such early emptying of the stomach that hunger pangs are felt too shortly after the meal is eaten.—Sherman, H. C. *Food and Health*. New York: Macmillan Company, 1934.

Certain changes in the skin of acne patients, which may "prepare the soil" or may constitute the entire pathologic condition, were, I believe first described by Unna⁵ in 1896. The earliest change noted by him consists of 'a superficial hyperkeratosis of the epidermis which, extending into the follicle mouths leads to the formation of comedones. In this stage the horny and granular layers become thickened. At the mouths of

Fig 2—Biopsy specimen of skin of patient F. A before treatment under low power showing hyperplasia of epidermis near mouth of sebaceous duct (A) and keratinized epidermis at B and C blocking the lumen. Normal gland tissue at D.

the follicles there is always found, instead of a filter-like depression a slight or marked elevation, formed of horny lamellae which is caused by pressure from beneath, of the horny plug." These are the comedones which are the product of a hyperkeratosis extending from the general surface to the mouths of the follicles and contain in addition to horny substance, normal sebum. They are consequently in no way the result of an abnormal secretion of sebum.

⁵ Unna P. J. The Histopathology of Diseases of the Skin (translated by Norman Walker) New York: Macmillan Company, 1936.

'There must be in acne,' says Unna, "some permanent irritant of the follicles, acting more or less deeply in the cutis, which induces a chronic hyperplastic inflammation." The epithelium participates, he believes, in the general hyperplasia. He also calls attention to the characteristic limitation of acne to the period of puberty.

Little interest was apparent in this obvious chronological relation until 1921, when Hollander⁶ advanced the theory that acne is caused by an endocrine imbalance brought about by the demands of puberty. This imbalance was, according to him, one of thyroid activity secondary to gonad activity.

In the same year Schamberg⁴ wrote "General experience will support the statement that practically all young female patients with acne exhibit a menstrual exacerbation of the eruption. When the phenomena of the menstrual acne relapse is considered in conjunction with the initial onset of acne at the approach of puberty the inference appears to be justified that an internal secretion of the sex glands or some other endocrine structure energized by the gonads is an etiologic factor of importance."

Other investigators (Pick,⁷ Bloch,⁸ Mumford,⁹ Van Studdiford¹⁰) have added confirmatory evidence to the support of the idea that the fundamental cause of acne is to be found in an endocrine imbalance incident to puberty.

Pick calls attention to the Bavarian colloquial term for acne lesions "chastity pimples" and states his belief that acne is connected with the function of the 'puberty glands'.

Bloch⁸ in a careful study of more than 4,000 girls and boys between the ages of 6 and 19, found some degree of acne in 59.6 per cent of the former and in 68.5 per cent of the latter. The severe grades were encountered in 8 per cent of the girls and in 20 per cent of the boys. He states that the process in the body which is responsible for the occurrence of menstruation and of the growth of pubic and axillary hair likewise determines the appearance of acne. "This process," he says "is the function of the gonads, and in this sense acne is to be considered as a hormonal skin disease."

Mumford⁹ calls attention to the fact that in a series of 100 female patients menstrual irregularity occurred or had occurred at the onset of the acne in 40 per cent, a finding which he regards as evidence that the eruption is a symptom of endocrine imbalance.

In our earlier paper, Feigenbaum and I¹ reported the results of treatment of fifteen patients with acne by injections of antuitin-S. The present paper comprises a study of thirty patients by the same method and a discussion of the results obtained.

So far as they parallel those of authors already cited, our observations are in essential agreement with them, and a detailed comparison seems unnecessary.

Three fourths of the patients were between 10 and 20 years of age, and in the remaining fourth the acne had appeared during adolescence in all but two, in both of whom it was preceded by changes in the rhythm and character of the catamenia. The onset of the eruption

was between the twelfth and fourteenth year in more than two thirds of the patients and in only one did it appear as early as the tenth year. Its severity was rated as mild in five patients, moderate in thirteen and severe in twelve. The eruption was confined to the face in fifteen cases, to the face and neck in two, and in thirteen was distributed over the face, neck, chest and back.

Ten of our patients were males, twenty were females. In the latter group a definite history of an exacerbation

significance was underweight of more than 10 pounds (45 Kg) in nine patients—about one third of the group.

Studies of the urine, blood, and basal metabolic rate were made as a routine. The urine showed no significant departure from normal in any case. The Hinton test was uniformly negative. Mild hypochromic anemia was found in four patients, the only departure from a normal blood picture. Blood cholesterol was normal in sixteen of twenty patients, and slightly increased in four. The basal metabolic rate was normal in eighteen patients between minus 10 and minus 20 in four, minus 29 in one, and between plus 10 and plus 20 in five. In the latter group the increase in metabolism was not accompanied by any other signs of thyroid hyperactivity and was thought to be due to emotional factors. The patients with depressed rates showed no physical or laboratory signs of thyroid deficiency. The fasting blood sugar was normal in every patient. Dextrose tolerance tests were performed on twenty-five patients. Fifteen showed the so-called flat curve indicating increased tolerance, in five the curves were indicative of a moderate depression of tolerance, and in five they indicated normal tolerance. Material for histopathologic study has been obtained from eight patients by biopsy and submitted to Dr. Osgood in our tissue laboratory. The results agree with those of Unna⁸ in indicating that the characteristic change in the skin is a superficial hyperkeratosis of the epidermis which blocks the follicle mouths and which represents a chronic hyperplastic process in which the epithelium shares in moderate degree.

Treatment consisted, as in our earlier series of injections of 2 cc of antutrin-S every other day.

Fig 3—Biopsy specimen of skin of patient F. A, before treatment under low power showing keratinization (A) hyperplasia of epithelium (B) and dilatation of the gland.

of the eruption at the menstrual period was obtained in eight patients, eleven had never noted any such relation, and one stated positively that it did not exist.

The menstrual periods were normal in only six of the twenty females, the remainder having disturbances of rhythm, duration or amount of flow, or definite dysmenorrhea. Oligomenorrhea was encountered more frequently than any other type of disturbance (present in eleven patients) but four patients had severe menorrhagia.

Genital development as observed in the males, was normal in nine patients. One showed definite genital hypoplasia. Satisfactory pelvic examinations in young girls are difficult to obtain, and definite criteria of normal development during adolescence are lacking so that our data concerning genital hypoplasia are meager. Three adolescent females showed in the opinion of the examiner definite genital hypoplasia, and the incidence of oligomenorrhea would suggest its presence in a considerably larger number.

No organic visceral disease was found in any patient in our series. The only physical finding of possible

Fig 4—Patient A. K. before treatment showing acne of face, absence of axillary and pubic hair, prepubertal breasts, and body configuration.

Injections were omitted during the menstrual periods of the female patients, though in no instance has there been noted any effect on normal menstruation, despite the well known influence of the preparation in disturbances of that function. This lack of effect in normal women has also been observed by Murphy, Shoemaker and Rea.¹¹ In the patients in whom there was coexisting

11 Murphy, D. P., Shoemaker, Rosemary, and Rea, Marion. Menstrual Response to Iuteinizing Extract of Pregnancy Urine. *Endocrinology* 18: 203 (March-April) 1934.

menstrual disturbance, improvement in both acne and menstruation progressed in equal measure, indicating a general effect on bodily economy rather than one localized in the skin. This generalized effect is well shown in patient A. K., a girl 15 years and 6 months old when treatment was begun. In addition to a well marked facial acne she showed definite retardation of

Fig 5—Patient A. K. after four months treatment showing decrease in acne lesions, development of breasts and beginning growth of pubic and axillary hair.

physical, mental and sexual characteristics. She had never menstruated, the breasts were prepubertal, and there was no body hair. After thirty days' treatment with antuitrin-S her acne was much improved. After six weeks' treatment there was definite growth of the breasts and a slight growth of pubic and axillary hair. Eight weeks after treatment was begun the acne was

Fig 6—Patient I. V. showing acne of face before treatment. Note in addition to papules and small pustules the general pebbly appearance of the skin.

greatly diminished the breasts showed further increase in growth and she had her first menstrual period.

The duration and amount of treatment necessary to produce results varied greatly in different patients. The factors which determined this variation were apparently the age of the patient and the severity of the disease, but even in patients of identical age and equally severe eruptions a rather wide variation of

response occurred. The average dosage in the series has been 3,360 rat units, the maximum 7,700 rat units in a patient 15 years of age with severe general acne and the minimum 300 rat units, in a patient 30 years of age with a mild eruption confined to the face and neck. No explanation of this variation is yet apparent, though the indications are that it depends on the gravity of the underlying imbalance rather than on its outward manifestation. In the majority of patients, improvement has been apparent in from two to four weeks, and maximum benefit has been obtained in from twelve to sixteen weeks. Two patients have shown slight relapses beginning four and six weeks after treatment was stopped and responding promptly to the resumption of treatment. No difference is apparent between the two sexes as regards response to treatment.

Ten patients are regarded as cured, since their acne has not reappeared after two months without treatment. Eleven are much improved, showing at present only an occasional papule, and seven show only moderate improvement, owing partly to as yet insufficient treat-

Fig 7—Patient I. V. after eight weeks treatment. Marked improvement in acne and loss of pebbly appearance of skin.

ment and partly to slow response. One patient has moved away and one has just begun treatment and was included in the series because of significant features in her case.

COMMENT

The evidence connecting acne with the profound changes in hormonal balance that take place during adolescence is so obvious that it has been overlooked until recently, and even now our knowledge of those changes is too fragmentary to permit identification of the exact endocrine dysfunction which causes this disease. Certain observations, however, can be assembled which narrow the field. The normal basal metabolic rates in 64 per cent of our series of patients with the additional finding of normal blood cholesterol values in 80 per cent of the patients tested seems sufficient evidence to eliminate disturbance of thyroid function as a factor. There is no evidence sufficient to indict the parathyroids and contrary evidence is offered by our finding normal blood calcium values in six patients. There is likewise no evidence of adrenal disturbance and the natural history of acne is inconsistent with present conceptions of adrenal function. The normal

fasting blood sugar values in our patients eliminate a pancreatic disturbance as a probability and leaves for more careful consideration the gonads and the pituitary as possible foci.

Certainly it is the secretions of these two glands which motivate the bodily changes which are defined as puberty and adolescence. Moreover, the work of

Fig 8—Patient J M showing acne of chest with marked scarring before treatment

Evans and his associates,¹² and of Smith,¹³ Engle,¹⁴ and Hertz and Hisaw¹⁵ has shown that such changes do not occur in the absence of adequate activity of the anterior lobe of the pituitary and that normal gonadal function is dependent on it. Houssay¹⁶ has also shown that that organ is intimately connected with carbohydrate metabolism. The evidence obtained from our studies, which brings to light a considerable association of acne with physical or sexual retardation and disturbances of menstrual function and of carbohydrate metabolism, furnishes a considerable indication that a hypofunctional disturbance of the anterior pituitary lobe is a factor of importance in the causation of acne. Finally, the response to treatment with a substance that is at least an anterior pituitary-like hormone offers confirmatory evidence of considerable weight. Such a hypothesis would predicate retarded gonadal development in acne patients and the fact that sexual hypoplasia could be demonstrated by physical examination in only a small number of our patients is not proof that normal physiologic activity was present in the remainder. The work of Rosenthal and Kurzrok¹⁷

indicates that in female acne patients at least, normal gonadal activity is the exception rather than the rule. They determined quantitatively both the gonadotropic and estrogenic content of the urine of thirty-four young women with acne. The patients' ages ranged between 11 and 33 years, twenty-one being under 20 years old. No gonadotropic substance was found by Zondek's method. Using Kurzrok and Ratner's method for the determination of the estrus-inducing hormone, they found it in normal amounts in only six cases present in traces in one case and completely absent in twenty-seven cases. These results indicate that, irrespective of the physical observations, a gonadal hypofunction, primary or secondary, does coexist at least in females, with acne. Primary ovarian hypofunction is uncommon before 20 so that it seems probable that the demonstrated hypofunction is secondary to a lack of the gonad-stimulating hormone of the pituitary. Again the normalization of the menstrual function in our acne patients treated with anturin-S lends weight to this supposition.

Treatment of a similar series of patients with anterior pituitary gonadotropic hormone should confirm or refute the theory that dysfunction of the anterior pituitary lobe is the basis of the hormonal imbalance that causes acne, while periodic hormone assays checked by endometrial and skin biopsies should furnish evidence adequate for the final solution of the problem of the role played by the gonads. Such studies are now being undertaken in our clinic.

CONCLUSIONS

Abundant evidence exists in the literature indicating that an endocrine imbalance incident to adolescence is

Fig 9—Patient J M showing condition of chest after five months treatment

the major, if not the sole etiologic factor in acne vulgaris.

From studies made in our clinic, it seems highly probable that this imbalance involves the anterior pituitary gonadal mechanism.

Further study is needed to determine the exact nature of the imbalance.

MULTIPLE MYELOMAS WITH TUMOR-LIKE AMYLOIDOSIS

A CLINICAL AND PATHOLOGIC STUDY

A. H. ROSENBLUM, M.D.

AND

J. D. KIRSHBAUM, M.D.

CHICAGO

The association of amyloidosis with multiple myelomas has been noted with increasing frequency in recent years, having first been reported by Askanazy¹ in 1903. Magnus-Levy² in 1933 summarized the literature on the subject and collected thirty-five cases of amyloidosis complicating multiple myelomas, to which he added two more cases recently reported by Chester³ and by Rosenblatt.⁴ These were collected from 150 carefully studied cases of myeloma, or an incidence of about 25 per cent. Of these, localized masses of amyloid simulating tumors were found in ten cases. Since his article, two additional cases have been reported by Rosenheim and Wright⁵ and by Randall.⁶ In the former, generalized amyloid deposits were found in

Fig. 1—Discrete areas of destruction throughout both tables of the skull

the bone marrow, liver and spleen, and in the latter the amyloid formed a tumor mass in the wall of the intestine causing an intestinal obstruction. Geschickter and Copeland,⁷ in a review of 425 cases of multiple myelomas do not mention the association of amyloidosis.

Amyloidosis may be classified as follows:

1. Primary or idiopathic amyloidosis, in which there is no apparent underlying suppurative or neoplastic condition. In this group there are two forms:

(a) The diffuse or typical form, as it occurs in the liver, spleen, kidneys, and so on. Associated diffuse

involvement of the bone marrow has been described by Geiber.⁸

(b) The localized or atypical form, in which a tumor-like amyloid deposit is present, as for instance in the larynx and the base of the tongue (Kramer and Som⁹ and others). In some cases amyloidosis has been observed in the muscles, trachea and lung. These tumors may also be multiple and may be combined with the diffuse form.

2. Secondary or symptomatic amyloidosis, in which a known preexisting cause is present, such as tuberculosis, neoplasms or chronic suppurative processes. In this group too there are two forms which correspond to the two forms of the idiopathic group:

(a) Diffuse involvement affecting typically the liver, kidneys, spleen and adrenals, or atypically in sites that are usually spared, as the viscera, muscles and bone marrow.

(b) Localized involvement, which may occur within neoplasms or chronic inflammatory areas or in the form of tumor-like amyloid deposits, especially in the upper air passages.

Combinations of these types are frequently present.

Cases of local amyloidosis at first regarded as idiopathic in origin have often shown on closer study an underlying myeloma, which can be easily overlooked in the presence of extensive amyloid deposits within the tumor tissue itself. The diagnosis is especially apt to be missed or even rendered impossible in those cases of isolated amyloid tumors occurring in organs such as the viscera or muscles, with the causative pathologic condition, the myeloma involving the bone marrow only. In these cases associated clinical and roentgen evidence of myeloma should be looked for and, even though not found, a biopsy of a rib is advisable. Thus, the number of cases of amyloidosis that are regarded as idiopathic would be minimized.

There also are cases in which local amyloidosis may occur with Bence-Jones proteinuria but without evidence of myeloma in histologic sections or on roentgen examination, as in the case of Michelson and Lynch.¹⁰ This type of case must still be included in the idiopathic group.

In multiple myelomas the deposition of amyloid may show the tendency toward the formation of isolated nodules or of solid masses, as illustrated by the case of Helly¹¹ in which a large pelvic tumor proved to be amyloid. In addition to the location within the myelomatous tissue, amyloid may also be present in the bone marrow, muscles and joints. The muscles were particularly involved in the case described by Paige,¹² with masses of amyloid up to 15 by 10 by 6 cm.

The following case is the twelfth one reported illustrating the formation of amyloid tumors in association with multiple myelomas.

REPORT OF CASE

History—E. S., a white woman, aged 39, married, entered the medical service of Dr. Tice in April 1935 complaining of marked weakness, stiffness in the joints with difficulty in moving about, inconstant pains in the sternum, chest, hips and spine, vomiting, and a "lump" in the sternum. She was in good health until November 1934, when she first noticed the dull

From the Department of Surgical Pathology (Dr. R. H. Jeffe, director), and from the Medical Service of Dr. Frederick Tice, Cook County Hospital.

pains as stated, which troubled her especially at night. A peculiar weakness developed four months prior to admission accompanied by a progressive stiffness in her joints causing her to become bedridden. The swelling in the upper part of the sternum was first noticed at this time also and after reaching its present size did not seem to grow much and was not tender. Vomiting was first noticed in January 1935, when it lasted for one month and was attributed to a thick slimy post-

Fig 2—Destruction of all the ribs on both sides complicated by many fractures. Some of the areas simulate an osteolytic neoplasm.

nasal drip. About one month prior to admission the vomiting recurred and was associated with the nasal drip. She had vomited at least once daily and often seven or eight times the vomitus consisting of food eaten or of stringy mucus. In spite of this her appetite was good and there had been no noticeable loss of weight.

The past history was essentially negative except for a premature menopause in 1931. The patient had been married six years but had never been pregnant.

Examination—On admission the patient seemed to be fairly well nourished and except for some pallor did not seem to be ill. The blood pressure was 148 systolic and 100 diastolic. The skin was soft and appeared warm, but there was no edema. Examination of the nasopharynx showed no apparent cause for a postnasal drip, and no discharge was seen. Over the manubrium there was a moderately firm nontender swelling about 5 cm in diameter and 2 cm in height fixed to the underlying tissues. Small nodules, which were slightly tender were felt in the ribs at the axillae. The examination of the lungs and heart gave negative results. The abdomen showed a smooth enlargement of the liver which extended 8 cm below the costal margin. The spleen was not palpable. The extremities could be moved freely without pain and the reflexes were normal. Fundoscopic examination was negative.

Course—The patient's condition remained about the same her chief difficulty being persistent vomiting which did not respond to any therapy, including administration of large amounts of sodium chloride. Edema was at no time present. Weakness increased somewhat accompanied by lassitude and after a stay of ten weeks in the hospital she insisted on going home. She left June 29, 1935 at which time her general condition was approximately the same. Her blood pressure on discharge was 60 systolic and 40 diastolic. Death occurred several days after she left the hospital.

Permission for a postmortem examination was not obtained but biopsies of the sternal mass and of a rib had been taken before the patient left the hospital.

Laboratory Examination—The blood Kahn reaction was negative. The icterus index was normal. The blood urea nitrogen June 14, was 171 mg per hundred cubic centimeters of blood and on June 20 was 151.75 mg. At this time the non-protein nitrogen was 285 mg and creatinine 12 mg. Cholesterol was 357 mg and the blood serum had a peculiar milky appearance. The total protein May 6 was 5.55 per cent. June 20 the serum albumin was 2.61 per cent and globulin 1.12 per cent, with a blood calcium of 7.45 mg and phosphorus of 4.76 mg per hundred cubic centimeters of blood. The blood indican was negative but tests for the blood phenols were moderately positive.

A congo red test as described by Shapiro¹³ was done May 14 and showed a strongly positive reaction for amyloid, since 90 per cent of the dye was removed from the blood stream in one hour. The urine remained colorless.

The blood examination April 5 showed hemoglobin 80 per cent, red blood cells 4,200,000, white blood cells 3,600. The differential count showed no abnormal forms. June 15 the hemoglobin had dropped to 60 per cent, red blood cells 3,100,000, white blood cells 4,000 and the differential count remained the same. Abnormal rouleau formation in wet and dried smears was not noted.

The urine showed many interesting features. It was usually straw colored with a peculiar opalescent appearance. The specific gravity ranged between 1.008 and 1.014. Albumin was constantly present in large quantities, but in the form of a proteose that could not be identified. It appeared at about 50 degrees but was not dissolved on boiling. Bence-Jones protein could not be found on numerous examinations by different chemists. Many white cells and granular casts were constantly

Fig 3—Small discrete areas of destruction in both iliac bones and in the lower ribs.

present but no lipid bodies. Phenolsulfonphthalein excretion by cystoscopy showed appearance of the dye in about twenty-six minutes from each ureter but only in small amounts. Stool and gastric analysis were essentially negative.

Röntgen Examination (by Dr C. H. Warfield)—There were many well defined discrete areas of destruction throughout both tables of the skull measuring from 2 to 7 mm in diameter (fig 1).

There were areas of osteolytic destruction in all the ribs, which were irregular in shape, broke through the cortex into the soft tissues, and were complicated by many fractures. Some of these areas were as large as 3 cm. in length and as wide as the rib (fig 2). There was no gross deformity of the thoracic cage. The dome of the left diaphragm was high, the heart was not enlarged, and no widening of the mediastinal shadows was observed.

The inner end of both clavicles was completely destroyed, though the cortex had been preserved. The entire sternum was decalcified. The manubrium showed osteolytic destruction due to what appeared to be a tumor extending posteriorly (fig 4).

Both humeri and femurs showed similar small discrete areas of destruction as seen in the skull (figs 2 and 5).

The tibia and ulna on both sides showed no destruction.

Both iliac bones showed small discrete areas of destruction similar to that seen in the skull (fig 3).

The lower dorsal and lumbar spines showed marked decalcification and moderate osteo-arthritis. There was a marked narrowing of the bodies of the first and second lumbar vertebrae.

The pyelogram on the right side showed a small pelvis elongation of the major calices and normal cupping and papillae. The left side was similar. There was a bilateral increase of the pulmonary hilus markings and thickening of the interlobar pleura of the left side.

No joint changes were noted.

Examination of the gastro-intestinal tract was negative.

SUMMARY

The roentgen examination of the skull and both iliac bones revealed conditions quite typical of multiple myeloma. The changes in the ribs and sternum suggested a metastatic osteolytic neoplasm.

A biopsy taken from the tumor mass over the manubrium sterni revealed microscopically fine and coarse wavy bands and masses of a structureless homogeneous material that stained diffusely with eosin. Scattered about were nests of small round

Fig. 4—Amyloid tumor in manubrium sterni and areas of decalcification through the sternum due to the osteolytic destruction.

cells and single foreign body giant cells which were found attached to the homogeneous masses. Occasionally the homogeneous masses were surrounded by a loose fibrillar connective tissue. No tumor tissue could be identified.

Congo red stained the eosinophilic material bright red. Fine deposits of a similar material were seen in the walls of the small arteries. The histologic diagnosis was tumor-like amyloidosis of the bone marrow.

A biopsy of a rib was subsequently taken in order to determine the cause of the amyloidosis. The medulla of the rib showed solid nests of cells, chiefly lymphocytes, and also round and oval cells with an ample cytoplasm and eccentrically placed nuclei, resembling plasma cells (fig 7). Occasionally there appeared to be transitional stages between the two cell types. Scattered about were small deposits of eosinophilic staining material. By special stains (congo red or gentian violet) this material was shown to be amyloid. The histologic diagnosis was lymphocytic myeloma with amyloidosis.

PATHOGENESIS

The origin of amyloid in multiple myeloma is still a question. Magnus-Levy² maintains that the most logical source is the bone marrow, which is responsible also for the abnormal euglobulin formation and Bence-Jones protein.

It is only a presumption that the destruction of the bone marrow produces the excessive amounts of proteins that are found in the blood stream in cases of multiple myeloma and in turn lead to stasis and the subsequent formation of amyloid.

However, Jaffe¹⁴ has shown experimentally that the formation of amyloid may be due to an acquired hypersensitivity to abnormal protein substances with the probable origin of the amyloid from collagenous tissue. The latter view also would furnish a more adequate approach to the etiology of the idiopathic amyloidosis.

COMMENT

A study of the literature indicates that the bone marrow is a frequent site of amyloidosis in cases of multiple myelomas. When present, the amyloid presents itself as isolated infiltrations in the wall of the vessels as massive accumulations in the form of tumors, and as isolated deposits within the preexisting myelomas. That the bone marrow may be diffusely infiltrated with amyloid unassociated with a preexisting blastoma has been shown in the cases of Gerber⁵ and others. In a series of nine cases of multiple myelomas examined by Jaffe,¹⁵ no amyloidosis of the bone marrow was found.

Clinically, our case presented practically all the features typical of multiple myelomas, modified to some degree by the presence of the complicating amyloidosis. Vague aches and pains in the joints, spine and chest could be attributed to amyloid infiltrations of the joints and joint spaces, as described by Magnus-Levy. However, these symptoms are often present in the absence of amyloidosis and without roentgen evidence of joint involvement. Symptoms of renal insufficiency, low

14 Jaffe R. H. Amyloidosis Produced by Injections of Proteins
Arch. Path. & Lab. Med. 1: 25-36 (Jan.) 1926.
15 Jaffe R. H. Personal communication to the author.

blood pressure and large amounts of protein in the urine are of common occurrence in both multiple myelomas and amyloid nephrosis. Roentgen evidence as in this case is usually most marked in the skull with numerous typical punched out areas of osteolysis. In other bones there may be a resemblance to a metastatic neoplasm (figs 2 and 5).

In most cases there is an increase in the blood proteins, identified by Magnus-Levy² as euglobulin which may rise to 8 per cent. The renal manifestations of our case can be attributed, at least in part, to an amyloid nephrosis with a fall in the blood proteins to about half of the normal, due to the large amount of protein lost with the urine. Perl and Hutner¹⁶ consider the myeloma kidney a chronic nephrosis with secondary contraction but Bell¹⁷ believes that obstruction of the tubules by casts of Bence-Jones proteins causes an atrophy and that there is no true nephrosis present.

The typical Bence-Jones protein could not be identified in our case. Instead an atypical proteose was present constantly in the urine in large quantities. It was very similar to the proteose described in the case of Rosenheim and Wright, and its formation is probably due to the same derangement of protein metabolism.

Fig. 6—Section of a biopsy of the tumor of the sternum showing large masses of amyloid and single multinucleated giant cells. $\times 400$

Interpretation of the roentgen appearance of the bones may become difficult when the myeloma is heavily infiltrated with amyloid as demonstrated in the roentgenogram of the ribs and may even take on the appearance of a metastatic osteolytic neoplasm. Biopsies should always be done in such questionable cases to facilitate an accurate diagnosis.

Fig. 7—Section of a biopsy of a rib showing lymphocytic character of the myeloma and beginning amyloidosis in the bone marrow. $\times 600$

CONCLUSION

A patient with multiple myelomas and a local tumor-like deposition of amyloid presented clinically the picture of multiple myelomas with a nephrotic syndrome. Death occurred from renal insufficiency.

In cases appearing as primary or so-called idiopathic amyloidosis either local or diffuse repeated biopsies are advisable to exclude the possibility of an underlying myeloma.

In all cases of multiple myelomas the congo red test should be performed in order to detect an eventually associated amyloidosis.

In multiple myelomas, instead of the typical Bence-Jones protein atypical proteins may be found in the urine possessing the same diagnostic significance as the former.

A Great Relief—It is a great relief to come from the world of public affairs where no one dares to admit that he does not know where no one ever admits that he has made a mistake where no one ever admits that he is puzzled into a world where it is respectable and honorable and safe to put aside the pretension of infallibility and of omniscience.—Lippmann Walter, Anniversary Discourse Before the New York Academy of Medicine *Bull. New York Acad. Med.* 11:673 (Dec.) 1935.

DIAPHRAGMATIC FLUTTER WITH SYMPTOMS OF ANGINA PECTORIS

WILLIAM B PORTER, MD

RICHMOND, VA

Diaphragmatic "tic" is sufficiently rare to justify one in reporting an authenticated example of this peculiarly interesting malady

The case to be reported is unique in that the movement of the minor contractions was recorded graphically and the rate was found to be 300 or more per minute, and a study of the diaphragm under the fluoroscope showed that the contractions were bilateral, spread over the entire diaphragm and apparently rhythmic in time and amplitude. The term "diaphragmatic flutter" is most appropriate and descriptive of the observed phenomenon.

There was associated with the disturbance of diaphragmatic function severe pain in the left pectoral muscle and in the left arm and hand over an area

Fig 1—Area of pain distribution and hyperesthesia

corresponding to the eighth cervical and the first, second and third dorsal segments of the cord (fig 1). Over the area of referred pain there was marked hyperesthesia, which persisted even after relief from pain followed cessation of diaphragmatic flutter.

REPORT OF CASE

J. C., a white man, age 57, a deep sea diver, admitted Feb 5, 1935, and discharged February 19, complained of a severe pain in the left side of the chest radiating down the left arm to the hand and accompanied by extreme anxiety and respiratory distress.

The patient was found ill on the sidewalk of the city. He stated that eighteen hours previously he had come to the surface from a diving bell without adequate decompression having been done. He felt no inconvenience from this until a few hours before the onset of the present illness at which time he was seized with agonizing pain in the left pectoral area accompanied by a cramplike pain in the left arm and the ring

and little fingers of the left hand. When seen in the admission ward he was begging to be put in an oxygen tent because he was convinced that he was suffering from caisson disease. He stated that he had had similar attacks in the past and that he was always promptly relieved when he was placed in an oxygen tent.

The patient appeared to be in great distress. The face was drawn and pale, and the body was fixed in a semirecumbent position with a tendency to lean toward the left side. He kept his hand constantly over the outer margin of the left pectoral muscle and was massaging at times the inside of the left arm and the ring and little fingers of the left hand. Cyanosis was notably absent. The first impression was that the patient was suffering from a serious cardiac malady and the examination was directed primarily to the heart and pulmonary system.

The heart was apparently normal in size and shape, rhythmic in action, with a pulse rate of 88. The sounds were distant but there was heard over the precordial area a to and fro shuffle which was interpreted as a pericardial friction rub. Blood pressure was 115 systolic, 45 diastolic. An immediate blood count showed a leukocyte count of 10,000 with 77 per cent polymorphonuclear leukocytes. An electrocardiogram taken while the patient was in the emergency ward showed changes strongly suggestive of coronary disease (fig 2). The mouth temperature was 101 F. There was made a tentative diagnosis of coronary occlusion with infarction of the heart muscle.

The patient was admitted to the hospital ward at 3 p. m. From this period until 9 o'clock the next morning he received three-fourths grain (0.05 Gm) of morphine, hypodermically, with only partial relief. When seen the next morning it was apparent that he was having pain in the same area and that there was marked hyperesthesia confined to the area of referred pain. At this time he was examined by a group of physicians who noted the following interesting facts: There was a striking pallor of the skin, which was sweaty and cold. The respiratory cycles were jerky and were occurring at a rate of 12 to 15 per minute. There had been no change in the pulse rate but the blood pressure was 100 systolic, 65 diastolic. Over the precordial area the adventitious sound previously noted was plainly audible, but it became apparent that the sound was not synchronized with the heart beat but was occurring at a rate of 250 or more per minute and was accompanied by, and synchronized with, a tremor in the epigastric area. It was also observed that the adventitious sound was plainly audible over the entire lower third of the chest both anteriorly and posteriorly and was best heard over the lower lobes near the lung margins.

Under the fluoroscope the diaphragm was seen to be moving on inspiration and expiration and there were superadded minor contractions, which were occurring at a rate of 250 or more per minute with an amplitude of about 1 cm. The minor contractions spread over the entire surface of the diaphragm on both sides, were apparently rhythmic, and could be best described as being a flutter of the diaphragm. With the assistance of the department of physiology a graph of the diaphragmatic flutter was recorded (fig 3).

It seemed reasonable to conclude that there was some connection between the clinical symptoms and the disturbed function of the diaphragm, and it was decided that blocking the phrenic nerve was a reasonable therapeutic procedure. This was done with procaine hydrochloride infiltration anesthesia of the left phrenic nerve, which immediately relieved the chest pain and the tremor previously noted in the epigastric area disappeared. An examination of the chest showed that the adventitious sound was no longer present and the fluoroscope showed that the left side of the diaphragm was not functioning, the right side of the diaphragm was moving normally, and there were no abnormal contractions on either side.

The patient remained comfortable for a period of seven hours when there was a recurrence of the pain, the epigastric tremor and the adventitious auscultatory phenomenon. He was again viewed under the fluoroscope and it was noted that there was a recurrence of the diaphragmatic flutter. As a matter of experiment the right phrenic nerve was infiltrated and the pain was immediately relieved. A restudy of the diaphragm under the fluoroscope showed that the right side of the diaphragm was not functioning but that the left was functioning normally and there was no tremor on either side. It was again noted that there was complete absence of the to and fro shuffle

sound that had been heard constantly during numerous examinations prior to the phrenic nerve block. It appeared therefore, that both the pain and the adventitious sound were in some way induced by the abnormal functioning of the diaphragm.

A very complete study was then instituted in an effort to determine the cause of the diaphragmatic disturbance. Roentgen studies were made of the sinuses, mediastinum, the entire gastrointestinal tract, the heart and the lungs. The sinuses showed

Fig 2—The changes in the T wave are the significant alterations in the electrocardiogram. A severe paroxysm of pain, diaphragmatic rate 300+. B no pain, normal diaphragmatic function. C onset of precordial pain with recurrence of diaphragmatic flutter.

slight haziness, and there was thickening of the descending branches of the bronchi with slight haziness at the bases of the lungs, which was interpreted as being indicative of a mild degree of bronchiectasis. The heart and aorta were entirely normal. While in the hospital the patient had a cough and expectorated from 1 to 2 ounces (30 to 60 cc) of mucopurulent sputum, and the temperature varied from 101 F to normal.

It was concluded that the fever and expectoration were indicative of a subacute pansinusitis complicated by bronchiectasis with infection.

The patient left the hospital against medical advice and with only slight modification of his clinical condition, except for those periods of marked improvement following the procaine infiltration.

COMMENT

The case here reported presents many interesting problems for consideration. The patient, after leaving the hospital, was traced through the Associated Press to other hospitals in the Eastern states. Through personal communication it has been possible to gather useful data concerning the further course of this patient. In one hospital where he was, the conclusion reached was that the patient was a morphine addict who voluntarily induced the disturbance of diaphragmatic function in an effort to secure the drug. This impression was held by one other observer who studied the patient.

It does not seem reasonable to conclude that this was the true situation. Our observations, which considered this aspect of the case seriously, convinced us that the man was seriously ill and that he sought morphine only because he was having severe discomfort. It is conceivable that he may have become habituated to morphine if it is concluded that the attacks of diaphragmatic disturbance continued to recur.

Cases of a somewhat similar character have been studied by observers both in America and in continental Europe. Gamble, Pepper and Muller¹ have reported an interesting case of a man, aged 38, who developed very rapid respiration during convalescence from an attack of encephalitis. The only subjective complaint was slight pain in the left arm and shoulder extending down to the elbow, with soreness of the right arm. The respiratory movements were recorded with a pneumograph and were from 60 to 90 per minute. Under the

fluoroscope the diaphragm was seen moving on inspiration and expiration, but there were superadded minor contractions to the larger excursions of the diaphragm. When the breathing was voluntarily controlled, the only motion of the diaphragm was the tic. This patient was permanently relieved by exposing the phrenic nerve on each side and freezing the nerve with an ethyl chloride spray. The respiratory rate fell immediately from 96 per minute to 20 per minute and remained so thereafter.

Simonin and Chavigny² have reported two cases observed over a long period, which they described as chorea of the diaphragm. In the first case the diaphragmatic disturbance apparently recurred over a period of more than two years. The rate of movement of the diaphragmatic jerks reached 60 per minute. The patient was manifestly a psychoneurotic individual and it was thought that the disturbance was hysterical in nature. In the second case the rate of the diaphragmatic tic was from

65 to 70 per minute and this was confirmed by fluoroscopic examination. It was bilateral and involved the entire diaphragm and is referred to as small rapid beats superimposed on the normal diaphragmatic contractions. The patient was followed for a period of twenty-seven months with little or no tendency to improvement. The final conclusion was that the disturbance was functional but probably in some way related to an attack of pleurisy that had occurred a few years previously.

Kulenkamp³ reports that a patient aged 27, during convalescence from what was thought to be encephalitis, had a disturbance of respiration which was found to be associated with a tremor or tic of the diaphragm. There were no subjective symptoms related to the cardiorespiratory apparatus. After a thorough study

Fig 3—Kymographic tracing during a severe paroxysm of pain. A diaphragmatic flutter, rate 300+. B tracing magnified photographically.

of the case he concluded that the diaphragmatic disturbance was in some way related to a central nervous lesion and that it was similar in its behavior to the shaking movements noted in postencephalitis paralysis agitans. He felt that the diaphragmatic tremor was of a similar nature and probably was related to a cen-

tral nervous lesion accompanying encephalitis. No definite statement is made, but the impression is that the case was followed for a prolonged period without any notable variation in the clinical symptoms.

From a clinical standpoint, one of the most interesting subjective disturbances occurring with diaphragmatic tic and flutter is the referred pain which in many instances closely simulates the pain of angina pectoris. Roemheld⁴ has described a clinical syndrome which he referred to as the "gastrocardiac syndrome" in which he attempts to describe a definite type of angina pectoris which he feels is related to disturbance of function in the stomach and colon.

Lurje and Stern⁵ have recently described a similar clinical entity under the head of "cardiodiaphragmatic syndrome." They believe that there exists a group of patients who have pain in the left thorax which is referred down the arm and which is associated with many of the cardinal symptoms of angina pectoris and is due entirely to malfunction of the diaphragm. After various manipulative measures, such as distending the stomach and colon with gas, they reach the conclusion that this syndrome is directly related to a hypotonus of the diaphragm which allows this structure to be pushed upward by a subdiaphragmatic collection of gas, which in turn disturbs cardiac function sufficiently to induce a group of symptoms similar in every respect to angina pectoris.

Winkler⁶ in a complete discussion of cardiac pain and its relation to diaphragmatic angina has reviewed the whole subject at considerable length. In this detailed review he is convinced that there exists a syndrome quite similar to that of angina pectoris associated with coronary disease, which is in some way related to the diaphragm. He concludes that, in the general consideration of the subject of angina pectoris, one must list as a special disease picture the diaphragmatic angina which has heart pain radiating pains and states of anxiety quite similar to that of Heberden's angina, and differing only in that there is rarely that acute sense of impending death. He feels that it is based on a group of reflexes which proceed from the diaphragm, which are partly sensory and partly motor in nature. He goes even further and recommends that the connection of the phrenic nerve to the sympathetic chains be interrupted surgically in an effort to cure the more intractable cases.

Similar conclusions have been reached by Hofbauer⁷ in which he describes attacks of angina pectoris, which he feels were definitely associated with and dependent on pathologic lesions of the diaphragm as well as disturbance of its physiologic function.

My experience with this patient convinces me that there is a syndrome which closely simulates angina pectoris and is directly related to a functional disturbance of the diaphragm. Just how much emphasis should be placed on the syndrome is difficult to decide. It is conceivable that disturbances of the diaphragm of a similar type to those observed in this patient may be more frequent than has been realized, for the clinical symptoms and physical phenomena are most elusive, and, judging from my experience with the case under discussion it would be quite explicable for one to class

the patient as a malingerer or conclude that a coronary accident had occurred, while the true nature of the illness goes unrecognized.

The diagnosis may be further confused by temporary alterations in the electrocardiogram made during the peak of a paroxysm. Just how these changes are produced is difficult to conceive, unless there occur in the myocardium nutritional alterations. The disappearance of the changes with cessation of diaphragmatic flutter suggests a direct relationship to the disturbance of diaphragmatic function.

My experience with this patient and others who suffered from lesser degrees of what was manifestly a similar clinical condition gives evidence that the most important differential diagnostic point between Heberden's angina and the "cardiodiaphragmatic syndrome" is that the latter condition is characterized by a notable absence of substernal pain and constriction and there is a tendency on the part of the patient to be restless, which is in bold contrast to the fixity of one undergoing an episode of angina pectoris.

The case here presented emphasizes the conclusions of other observers that there exists a clinical condition which is justifiably described as cardiodiaphragmatic angina.

ESOPHAGITIS

A CLINICAL STUDY

PORTER P. VINSON, M.D.

AND

HUGH R. BUTT, M.D.

Fellow in Medicine the Mayo Foundation

ROCHESTER, MINN.

The esophagus usually is considered immune to the usual diseases that attack other organs of the body. Much has been written concerning carcinoma and stricture of the esophagus and cardiospasm, but little has been written about the most common disease of the esophagus—esophagitis.

In a recent study, we¹ found the incidence of esophagitis to be 7.02 per cent in 3,032 necropsies performed. Definite symptoms occurred in 10.3 per cent of the 213 cases in which a pathologic diagnosis of esophagitis was made. Although in thirty-two cases (10.3 per cent) there were definite symptoms that suggested esophagitis a clinical diagnosis was made in only one case. All the information obtained concerning the symptoms of esophagitis was volunteered by the patients. It seems reasonable to suppose that, if the patients had been questioned as a routine with regard to the symptoms of esophagitis, the percentage of patients who had symptoms which suggested esophagitis would have been increased and the clinical diagnosis would have been recorded more frequently than it was.

OCCURRENCE

The anatomic structure of the esophagus makes it vulnerable to the organisms of the oral cavity, the regurgitated gastric contents, and infection through the blood stream and the lymphatic structures from the abdominal viscera. Esophagitis is most frequently the accompaniment of diseases in which there is frequent vomiting and in which passage of a stomach tube is

employed in treatment Tileston² and Sheehan³ observed that esophagitis was favored by stenosis of the pylorus or duodenum, which led to frequent vomiting. We recently have shown that the incidence of gastric intubation and vomiting closely parallel the increased incidence of esophagitis.

Moutier⁴ reported several cases of postoperative esophagitis, and we found that in 159 (74.6 per cent) of 213 cases of esophagitis the disease had followed some form of operative procedure.

Jackson⁵ observed evidence of chronic foci of infection in 90 per cent of cases of "peptic ulcer" of the esophagus and Mosher⁶ noticed the frequent association of this condition with infection of the gallbladder. Moersch and Camp⁷ suggested that intra-abdominal infections such as cholecystitis, duodenal ulcer and appendicitis, might be carried by lymphatic vessels to the esophagus and give rise to localized esophageal infection.

The work of Cushing⁸ and that of Masten and Bunts,⁹ stress the frequency and danger of esophageal inflammation in tumors of the brain and in other conditions which involve the central nervous system.

The relationship between esophagitis and superficial burns, diabetes mellitus, arteriosclerosis and many other conditions had been recorded in the literature.

SYMPTOMS

The most common symptom of esophagitis usually is described by the patient as a "burning" in the thorax. This occurred in seventeen (53.2 per cent) of the thirty-two cases in which symptoms were present. This burning pain is most often in the back and lower third of the sternum. The pain, as pointed out by Eusterman, Moersch and Camp,¹⁰ often simulates the pain described in histories of cases of peptic ulcer. In fact, Rivers¹¹ observed that 45 per cent of his patients with esophageal ulcer gave a history which simulated that of peptic ulcer.

Hematemesis and melena have been reported as symptoms that occur in the course of esophagitis. The former is the most common type of bleeding in this condition. Pringle and Teacher¹² have emphasized the importance and danger of postoperative hematemesis. Anesthetic agents have been accused by some writers, and no doubt these agents do often excite vomiting, but just how they could produce bleeding we cannot understand. In our series of 213 cases hematemesis occurred in fifteen (40.8 per cent) of the thirty-two cases in which there were symptoms. It was the second most frequent symptom. The amount of blood that was vomited varied from a few cubic centimeters to

200 cc. A few of the patients vomited blood on several occasions. Grossly, all the lesions presented acute ulcerations and involved the lower third of the esophagus. In one case the entire esophagus was involved. In none of the cases in which hematemesis was present was the esophagus suspected clinically as being the source of the bleeding. At necropsy, no other lesion which could account for the bleeding was found in the upper part of the alimentary tract, except the ulcerated esophagus.

Dysphagia was present in nine cases (28.1 per cent), the probable cause of this symptom was spasm of the esophagus which resulted from the inflammatory lesion. Dysphagia frequently was accompanied by substernal pain. In a few cases the dysphagia was so severe that it was necessary to feed the patient with a tube.

As Barclay¹³ pointed out, the patient with esophageal ulcer may go through all the stages of hypertrophy, pain, obstruction and starvation and often may remain comfortable in a stage of semistarvation.

In twenty-three (71.9 per cent) of these cases, esophagitis followed operation. The symptoms usually appeared from twenty-four to forty-eight hours after operation and continued for from three to ten days. In the remaining nine cases, in which operation was not performed, the symptoms usually began several days before death. In a few of the cases in which gastric intubation was employed the symptoms appeared a short time following the procedure.

DIAGNOSIS

Substernal burning and pain, hematemesis and dysphagia are the most common symptoms. Whenever any of these symptoms occur, the diagnosis of esophagitis should be considered. This is especially true if the symptoms appear following vomiting, gastric intubation or infection.

Jackson, in discussing Winkelstein's¹⁴ report, said that esophagoscopy was indicated in every case in which unyielding gastric symptoms were present. Levine¹⁵ also found this method of use in the diagnosis of esophagitis.

Barclay and others have stressed the importance of roentgen rays as a diagnostic procedure. Usually there is spasm of the lower third of the esophagus without dilatation. Administration of belladonna according to Barclay relieved the spasm in some cases, whereas in other cases it had no effect. The severity of the spasm does not appear to depend on the degree of inflammation. Otell and Coe¹⁶ described spasm as the chief roentgenographic characteristic of ulcer of the esophagus, but according to these authors "the roentgen appearance in acute esophagitis shows no variation from the normal."

TREATMENT

The simplest treatment of esophagitis is prevention. Less trauma in the passage of stomach tubes certainly would decrease the incidence of the disease. Vomiting should be controlled as much as possible. If pain becomes severe, dissolving ethyl aminobenzoate lozenges in the mouth and swallowing the saliva may be helpful. An icebag to the sternum and neck often will

give relief Bastedo, Friedenwald and Soper¹⁷ give many helpful suggestions in their recent symposium Soper pointed out the value of a bland, smooth diet and the usual difficulties encountered when alkalis are administered Olive oil and cool milk have been suggested as helpful therapeutic procedures We advocate the administration of tincture of belladonna, in doses of 20 drops (12 cc) every three or four hours for relief of spasm, a soft diet, and sedatives for pain Morphine sulfate in small doses is administered when the pain is severe Feeding with a tube and measures to prevent vomiting should be employed

When the condition results in the formation of an ulcer, Barelay found that the passage of a bougie may so stretch the base of the ulcer that healing and complete relief of all symptoms may follow

CONCLUSIONS

1 Esophagitis is the most common condition affecting the esophagus

2 It should be suspected when substernal pain, dysphagia or hematemesis is present Hematemesis which occurs at any time, but especially that which occurs after operations or any acute illness, should make one suspect the esophagus as its source

3 It is advisable to perform esophagoscopy in every case in which there are unyielding gastric symptoms

THE PREVALENCE OF VITAMIN A DEFICIENCY AMONG IOWA CHILDREN

P C JEANS, MD

AND

ZELMA ZENTMIRE, MS
IOWA CITY

In 1934 we¹ described a photometer test for dark adaptation which we believed useful in detecting vitamin A deficiency Subjects with impaired ability to adapt to the dark were found to attain normal standards of dark adaptation after a period of vitamin A ingestion The study that was reported seemed to establish the validity of the dark adaptation test as a test of vitamin A deficiency With the photometer test being used as the criterion, a survey was made among Iowa school children in an endeavor to determine the frequency of vitamin A deficiency This presentation is for the purpose of recording the results of the survey

The first phase of the study, i e, the original testing, was conducted in 1934 from February to April inclusive The total group examined comprised 404 children from 6 to 15 years of age selected at random from rural, village and urban schools The village selected was a county seat of approximately 2,000 population The children of the rural group were from numerous small schools located within a 10 mile radius of the selected village, they were transported to the village for the test All the village and rural children were examined in the same dark room and under the same standardized conditions The urban children were in a city of approximately 150,000 population and

were attending four different schools Though the examinations were made in four different places, the conditions of the test were thoroughly standardized in each location The urban children were classified according to the economic levels of their parents Many of the families at the lowest economic level were receiving assistance

The results of the survey are most readily comprehended by examination of table 1 A distinction has been made between those with borderline subnormal and those with definitely subnormal dark adaptation Considering only those definitely subnormal, it was found that the proportion having poor dark adaptation in the rural group was 26 per cent and in the village group 53 per cent, in the urban group the proportion in the upper economic level was 56 per cent, at the middle level 63 per cent and at the lowest level 79 per cent Analysis of our data failed to reveal any relationship between vitamin A deficiency and either age or sex

The results obtained were definite and clean cut and no obvious reason was apparent for doubting them However, the proportion of subnormal results was so unexpectedly high that it was thought best to continue the study by reexamining some of the children after a period of vitamin A ingestion An attempt was made to include in this second phase of the study all the rural and village children who had had borderline or definitely subnormal results at the first testing For a period of several weeks either halibut liver oil or carotene in oil was administered each school day by the teachers Those who did not show normal dark adaptation by the time school closed were given one of these products to use at home and at the same time we started bringing the children in small groups into the Children's Hospital and retaining them until normal dark adaptation was attained Of the total group of ninety nine rural and village children whose tests had shown abnormal results, all except twelve continued under observation The reasons for these twelve exceptions were illness, removal from the district or lack of cooperation These twelve children did not receive a second test Nine other children were observed and tested further but did not continue to the completion of their study Six of these were dropped from the

than the frequency of deficiency. Approximately 50 per cent of the children examined in the first study were orthopedic and pediatric patients who had been hospitalized repeatedly and in some instances at short intervals for treatment of chronic afflictions not affecting their nutrition. In retrospect it appears that the effect of hospital diet and the dietary instructions given

* Only a brief period of observation permitted

† After approximately six weeks of treatment

for home care offer sufficient explanation for the discrepancy apparent in the incidence figures of the two reports.

The data presented in table 2 show that of the seventy-eight children who continued under observation only three failed to attain normal dark adaptation. These three remained in the hospital for from three to six weeks and it was impracticable to keep them longer. Careful ophthalmologic examination failed to reveal any abnormality that would account for the poor dark adaptation. It would be only conjecture to state that a protracted period of vitamin A deficiency may have produced a refractory state and that possibly a longer period of vitamin A ingestion would have brought about improvement. We have noted that the children who required the longest stay in the hospital to attain normal dark adaptation, as well as these three who did not become normal, were those who did not like foods rich in vitamin A or carotene. If these three children are considered to represent exceptions to the rule that the dark adaptation test is a test of vitamin A deficiency, the test is still more than 95 per cent efficient when applied in a large scale survey.

The halibut liver oil and carotene in oil were administered in dosages computed to be approximately equivalent to the vitamin A content of 3 teaspoonfuls of cod liver oil daily. Of the children whose dark adaptation was subnormal the great majority attained normal adaptation within a period of a month after starting ingestion of vitamin A. At the dosage levels used, no difference was detected between the effectiveness of vitamin A and of carotene.

The second phase of this study gave evidence in addition to that in our former report that the test described is useful in detecting vitamin A deficiency. Also the conclusion seems permissible that the test may be used in large scale surveys with small chance of error even if expert medical consultation is not employed. It is indicated also that vitamin A deficiency is much more prevalent than usually has been assumed.

Two other studies of the prevalence of vitamin A deficiency among school children have been found in the literature. Widmark and Svensson² examined approximately 1,200 children from all economic and social strata of the manufacturing and seaport city of Malmö, Sweden, with a population of 120,000. They

used the photometer test of Edmund, which consists of a single test of vision immediately on entering a dark room and without a period of adaptation. Only nine children were thought to have vitamin A deficiency. Frandsen³ found slight hemeralopia in forty-six of sixty-five apparently healthy school children of Copenhagen, latent hemeralopia was present in seventy of seventy-two children examined as private patients for eye complaints. Improvement or cure was produced by the administration of cod liver oil for several weeks or months. The degree of night blindness was determined by the ability to distinguish letters of varying shades from black to faintest gray on a white background, in a light of constant dimness, after an adaptation period of from five to ten minutes.

SUMMARY

Using a test for ability to adapt to the dark as the means for detecting vitamin A adequacy, we found that 26 per cent of a rural group and 53 per cent of a village group of Iowa children presented evidence of vitamin A deficiency, in an urban group the proportion for the higher economic level was 56 per cent, for a middle level 63 per cent and for a low economic level 79 per cent. Of the seventy-eight village and rural children who were deficient in vitamin A and who continued under observation, all except three developed normal dark adaptation after a period of vitamin A or carotene ingestion.

TRANSFUSION OF CADAVER BLOOD

S. S. YUDIN

Surgeon in Chief of the Surgical Clinic of the Institute Sklyafosvsky
Central Emergency Hospital, Director of the Surgical Clinic
Post Graduate Medical School

MOSCOW

The striking results of V. N. Shamov in experiments on dogs and the special conditions of the work in my clinic, frequently requiring immediate blood transfusion, stimulated me to attempt the use of cadaver blood for transfusion in human beings. My first experience was with the case of a young engineer who slashed both of his wrists in a suicidal attempt. He was brought to our hospital pulseless and with slow, jerky respiration. Transfusion with 420 cc of blood taken from the cadaver of a man, aged 60, who had been killed in an automobile accident just six hours before, promptly revived him.

My assistants Dr. M. G. Skundina and Dr. S. I. Barenboim¹ studied in dogs the oxygen exchange according to Barcroft before bleeding, after partial exsanguination, and after transfusing these animals with blood taken from dogs killed a few hours before. They were able to show that cadaver blood when transfused into animals dying of acute anemia was capable of reviving them and that it immediately raised the oxygen content of the blood and participated actively in the gaseous exchange. They further demonstrated that cadaver blood preserved its living properties in the blood vessels of dogs for from six to eight hours when the cadavers were kept at a temperature of 1 or 2 degrees above zero. Studies in human beings showed

that the hemoglobin of the recipient rose immediately and that the volume percentage of oxygen became materially raised

A series of forty-nine clinical cases demonstrated the therapeutic effectiveness of the new method. Cadaver blood did not exhibit any toxic effect and its therapeutic results were not different from those obtained with the blood from living donors. There remained, however, the problem of the Wassermann reaction. It was solved when I demonstrated that cadaver blood can be preserved in a refrigerator. I took the chance of transfusing a patient, bleeding to death from a gastric ulcer, with the remains of unused blood kept in the refrigerator for three days. The patient's condition improved to such a degree as to enable me to perform the difficult operation of stomach resection for a deep duodenal ulcer penetrating into the pancreas. Further studies demonstrated that it was possible to keep the blood in a citrate solution for as long as four weeks. Thus, of course, solved the problem of the Wassermann reaction. It likewise made it possible to check up on the sterility of the preserved blood by cultures. This together with a careful necropsy performed on each cadaver, protected the recipient to the fullest degree.

We soon learned to select the more suitable cadavers, such as those of persons dying in an attack of angina pectoris, those killed by an electric current or those who hanged themselves. From 2 to 3.5 liters of blood can be easily obtained from a cadaver that is not damaged and that amount will suffice for five or six average transfusions. Before long we not only had enough blood for our own clinic but we were able to supply it to a number of hospitals and even send it to distant points.

The technic of withdrawing blood is simple. The jugular vein is severed and a glass cannula to which a rubber tube is attached is introduced into each end of the vein. The cadaver is then placed in the Trendelenburg position and the blood is allowed to run into a 500 cc glass flask. The neck of the bottle is stoppered with cotton and the bottle is placed in a refrigerator where it may be kept for one month.

My assistants Dr M. G. Skundina and Dr A. W. Rusakov demonstrated by carefully following the post-mortem injection technic that, after the injection of the cadaver with methylene blue, blood drawn from the jugular vein will not show any trace of the dye. It appeared that blood flowing from the jugular vein drains the systemic veins flowing into the superior and inferior venae cavae and not those from the lesser and the portal circulations. This is important in view of Shamov's observations that blood in the mesenteric veins is the first to become infected after the death of an animal. At room temperature, infection from the bowel will enter these veins after twenty hours. Because of this we decided to put the limit of usability of a cadaver at six hours for the summer and eight for the winter.

The researches of Skundina and Rusakov² on some 500 cadavers established interesting facts regarding the coagulation of the cadaver blood. They found that the coagulation of the blood and the further behavior of the coagulum depended on the cause of death in a given case and on the duration of the antemortem agony.

Blood of healthy individuals who died suddenly in traffic accidents, in drownings, in a heart attack or from an apoplectic stroke, rapidly coagulated if removed in the first few hours after death. The coagulated blood, however, returned in from one-half to one and one-half hours to the fluid state and would not coagulate again. Warming and shaking the blood accelerated the liquefaction or fibrinolysis, while saturating it with oxygen retarded the fibrinolysis. A number of sensitive biochemical tests failed to demonstrate the splitting up of the albumin molecule. For example, there was no increase in the serum of the residual nitrogen. They have succeeded in demonstrating that fibrinolysis here took place because of the gradual disappearance of the main component—the fibrinogen. A. W. Rusakov observed with the aid of an ultramicroscope the fine fibrin network break up into the tiniest kernels, which would not pass a filter.

Blood of individuals dying slowly showed an abnormally high sugar content while the blood of those dying after prolonged agony showed normal amounts. The high sugar content did not come from the so-called bound (tissue) sugar, if we assumed that splitting of the albumin molecule took place. Skundina and Rusakov were able to show that the source of sugar was the large hepatic veins for if they succeeded in operatively removing the liver before killing the experimental animal (rabbit or dog) the rise in the blood sugar did not take place. The increased sugar content, however, is no drawback to transfusion, because even in the massive transfusions it amounts to not more than 2 Gm.

There is a practical as well as a theoretical significance in the phenomenon of fibrinolysis occurring in the blood of individuals who die suddenly. Dr Skundina called attention to the fact that we have here "a paradoxical phenomenon in that the blood of sick people dying after an agony does not differ in its coagulating properties from the blood of the living, while the blood of individuals dying suddenly possesses the property of first coagulating and later reliquefying". Its behavior in this respect is analogous to that of blood extravasated into the peritoneal or the pleural cavity.

A. A. Bocharov, one of my assistants, recorded an interesting observation. Blood drawn from two accident cases, brought to the institute in a state of shock, underwent fibrinolysis and remained fluid. One of the patients died in spite of the measures resorted to in order to save him, while the other recovered after an operation and a massive blood transfusion. His blood on recovery coagulated normally. A profound shock is a state close to death. It would appear that in a shocked patient fibrinolysis begins while the patient is still alive.

The practical advantages of the phenomenon of fibrinolysis are, first that one can tell the fitness of the blood by observing its behavior with regard to coagulation even before the necropsy is performed, and secondly that this blood can be preserved without the aid of an anticoagulant. Blood preserved without the addition of the citrate solution undergoes hemolysis more rarely and after a longer interval. But what is more important is that while the citrate blood gives about 20 per cent of mild reactions, that without the citrate gives about 5 per cent.

The technic of transfusion consists of warming the blood to body temperature by placing the flask con-

² Skundina, M. G., Rusakov, A. W. and others. Transfusion of Cadaver Blood Without Preservatives. *Soviet Med.* 7: 194 (Nos. 2 and 3) 1934. Skundina, M. G., Ginsberg, R. E. and Rusakov, A. W. Biochemical Changes in Cadaver Blood. *ibid.* 1935 No. 6 p. 78.

J. Yudin, S. S. La transfusion du sang de cadavre à l'homme. *monographie* publiée par Prof. A. Gosset. Paris: Masson & Cie. 1933.

turning the cadaver blood in warm water. The blood is then passed through a gauze filter into the vessel from which it is to be transfused. The transfusion can be performed with the aid of a Jubee or a Tzank syringe or by the gravity method from an ordinary funnel. The transfusion is performed slowly, always after an introduction of some physiologic solution of sodium chloride. A biologic test with from 10 to 30 cc is obligatory in every case.

We have not observed toxic manifestations in a series of almost 1,000 transfusions of cadaver blood. The seven fatalities occurring in our series were caused in each instance by a technical error and were not caused by the cadaver blood as such. In one case the necropsy established air embolism as the cause of death; in another, death was due to an anaerobic infection developing at the site of venesection. Two fatalities were caused by faulty grouping and incompatible blood. In three cases a typical picture of hemolysis was present.

The therapeutic results did not differ from those obtained by transfusion of blood from living donors. The particular advantage of our method is made evident in those acute emergencies in which the loss of time entailed in calling the donor and obtaining blood from him may prove fatal. Profound shock developing in the course of a brain operation or a prolonged laparotomy furnish just such emergencies. To warm up the blood removed from the refrigerator takes five or six minutes. Another valuable feature is the possibility of using blood from the same cadaver for repeated transfusions. It is obviously impossible to take from 450 to 500 cc of blood from a living donor at intervals of half an hour for three transfusions. This, however, becomes necessary in grave traumatic shock in which the effect of the first transfusion is spent about the time the amputation is begun, while the effect of the second transfusion performed during the operation lasts only a short time, making it advisable to give a third one. It is not safe to change donors in the course of anesthesia because there is no time for the performance of the biologic test. The problem is solved by having in stock preserved cadaver blood. The greater the loss of blood and the less there is of the patient's blood to mix with the transfused blood, the more important is the question of ideal compatibility. Having given some 200 or 250 cc of blood while preparing for the operation and being convinced of the compatibility of the blood, one need not hesitate to use the same for a second and, if need be, for a third transfusion.

Experience in our clinic with more than 300 cases of acute gastric duodenal hemorrhage has demonstrated that it is best to operate on these patients at once if they enter in the first twenty-four hours. They require however massive blood transfusion during and immediately after the operation. Conditions are much graver when patients are admitted after repeated hemorrhages from three to four days after the initial bleeding. Here it is safer not to operate but to treat them with oft repeated small transfusions.

I was however compelled as a last resort to operate in some of these cases. The occasional saving of such a patient in my opinion was in no small degree due to repeated massive transfusions of blood from the same source kept for just such occasions.

Two recent cases demonstrate these statements.

A 17 year old boy was admitted to our clinic Feb. 26, 1935 because of a profuse gastric bleeding. His pulse was 112, hemoglobin 17 per cent, blood group A V. An immediate transfusion with 20 day old blood of the A V group had the

desired effect. The vomiting stopped, the skin became pink and the general condition was satisfactory. On the following day he developed pallor, loss of consciousness and imperceptible pulse. There was profuse tarry stool. Transfusion of 150 cc of blood of group O again revived him. During the night another hemorrhage took place and the patient was in imminent danger of dying. The resident surgeon gave a transfusion with 350 cc of blood from the same source as the previous transfusion. Feeling that conservative measures would not avail here I decided to operate. A laparotomy performed under local anesthesia revealed a deep duodenal ulcer penetrating into the pancreas. As soon as the main gastric blood vessels were ligated, transfusion with compatible blood A V was begun. By the time the operation of gastric resection was ended the patient had received 1,100 cc of cadaver blood. He made an uneventful recovery.

In the following case, blood from one source was used each time.

This patient was brought to the clinic in fairly good condition following a single hemorrhage. He refused operation. Because of signs of internal hemorrhage, a transfusion with 280 cc of cadaver blood was given. The condition improved but two days later he had another hemorrhage and his hemoglobin was now 28 per cent and the number of red cells 1,750,000. The next day there was another hemorrhage and this time 300 cc of blood was given. I again urged an operation, but the patient declined. Two days later he vomited a quantity of blood and became pulseless. His condition again improved after transfusion of 200 cc of blood. The hemoglobin was 12 per cent and erythrocytes numbered 900,000. The patient now expressed the wish to be operated on. Hematemesis during the night rendered him a hopeless risk. As a last resort I operated under local anesthesia and demonstrated a large callous ulceration high up on the lesser curvature. On ligation of the gastric vessels transfusion was started and by the time the first Billroth resection was completed 1,000 cc of blood and 500 cc of physiologic solution of sodium chloride were infused. The patient was removed from the operating table in good condition and made a good recovery. His hemoglobin before the operation was 12 per cent and the number of erythrocytes was 900,000. Immediately after the operation the hemoglobin was 34 per cent and the number of erythrocytes 1,900,000. At the time of leaving the hospital his hemoglobin was 32 per cent and erythrocytes 2,360,000.

Our experience with cadaver blood transfusions embraces 924 transfusions. Besides our clinic sent out more than 100 flasks of cadaver blood to various hospitals and clinics.

CONCLUSIONS

- 1 Transfusion of cadaver blood was demonstrated in animal experiment and proved its therapeutic value in a considerable clinical material.

- 2 Cadaver blood obtained from six to eight hours after death remains sterile and preserves its living properties.

- 3 The recipient of cadaver blood is afforded ample safeguards by serologic tests of the blood, a bacteriologic checkup as to its sterility, and a careful necropsy.

- 4 Because of fibrinolysis blood of individuals dying suddenly remains fluid and can be preserved for more than three weeks.

- 5 The therapeutic effect of cadaver blood does not differ from that of blood from living donors.

- 6 The technic of obtaining blood from a cadaver is simple and does not require any special apparatus.

- 7 Organization of stations for collection of fresh cadaver blood should offer no difficulties in the larger cities, particularly in the large hospitals for emergency cases. The supply could come from traffic accidents as well as from the medical service where deaths from coronary thrombosis and angina pectoris are not rare.

THE RELATIVE IMPORTANCE OF SPECIFIC SKIN HYPERSENSITIVITY IN ADULT ATOPIC DERMATITIS

MARION B. SULZBERGER, MD

AND

JOSEPH GOODMAN, MD

NEW YORK

The idea that certain skin diseases are due to changes in the "nerves"—and even in the psyche—is by no means new. However, such changes have been constantly and conclusively demonstrated in only a small minority of dermatologic entities, for example, herpes zoster, syringomyelia, nervous leprosy, the facies oleosa of parkinsonism, and certain cases of pruritus vulvae and pruritus ani.

There is another group of dermatoses in which the psychoneurogenic factor has been stressed but admittedly not conclusively proved. Nevertheless, many authors continue to give serious consideration to the possible role of the psyche and of the nervous system in these dermatoses.

One clinically important representative of the latter group is "generalized neurodermatitis." The very name that Brocq and Jacquet in 1891 gave this dermatologic entity—"neurodermite diffuse"—expressed their opinion as to its "nervous" origin. This opinion has continued to be shared by many good observers among whom, most recently, have been Stokes¹ and van de Eive and Becker.²

A newer concept is advanced by such authors as Rost,³ Sulzberger, Spain, Sammis and Shahan,⁴ Coca,⁵ Hill and others.⁶ These observers considered specific vascular skin hypersensitivity to foods and/or to environmental allergens to be the essential factor in the production of disseminated neurodermatitis. The apparent relationship between disseminated neurodermatitis and hay fever, asthma and infantile eczema—the "atopic" diseases (Coca)—has led several of these authors to propose substituting the name "atopic dermatitis" for "disseminated neurodermatitis" or "neurodermatitis disseminata." Hereafter, we shall employ the name "atopic dermatitis" in place of any of the older terms such as disseminated neurodermatitis, pruritus with lichenification, prurigo diathesique, flexural eczema, and hay fever eczema.

In consideration of the apparently conflicting opinions held by these two schools, we believe it may be of interest to review our observations in more than fifty cases of typical adult atopic dermatitis, with particular reference to these two contrasting points of view.

In our cases of this dermatosis (not uncommon in New York City), certain characteristics occurred with sufficient regularity to enable us to set up a composite picture of the syndrome of atopic dermatitis.

FAMILY HISTORY

Roughly, in more than half of our cases, one or more members of the family have or have had one or more of the atopic diseases.⁸

It seems to us that this familial atopic background speaks in favor of the atopic nature of the dermatosis under consideration, for even in vasomotor rhinitis and asthma the familial history of atopy is present in only about 50 per cent of the cases.

Unfortunately, we have been unable to determine the neurologic and psychiatric heredity in our cases. As dermatologists, we have found it to be beyond our powers to elicit and evaluate the psychiatric and neurologic family histories of our patients.

PERSONAL HISTORY

More than half of our cases were associated with one or more atopic diseases. Thus, here again, the conditions found are analogous to those in vasomotor rhinitis, and particularly to those in asthma, in which fully 50 per cent are without history of other atopies.

In our material we encountered no preponderance of manifest psychic or neurologic disturbances. In fact, our patients in this group impressed us as being neither more nor less "nervous," irritable or psychopathologic than any group of patients suffering from other chronic, distressing and sometimes disfiguring and incapacitating dermatoses. On the contrary, our atopic dermatitis patients, as a group, impressed us as showing fewer psychoneurotic tendencies than were found, for example, in a group of patients with moderately severe acne vulgaris.

We know of no way of accurately gaging such imponderables as "nervousness," "tension states," "temperamental difficulties" and "protoplasmic instability." Therefore, in gaining our impressions, we have been obliged to rely solely on close clinical observation.

Of course, we have encountered "nervousness," irritability and the like in a few of our cases. But we wish to emphasize that we have found no proof that this "nervousness" is a causal factor in the production of the dermatosis. In our material we have gained the impression that these occasional instances of "nervousness" were (1) purely coincidental, (2) concomitant (i. e., psychoneurologic disturbances caused by the same factor or factors producing the dermatologic manifestations) or (3) clearly the comprehensible result of the normal reaction to the dermatosis and its "maddening" itching, loss of sleep, continuous worry about the appearance, and related conditions.

COURSE OF THE DERMATOSIS

Although we are here concerned only with atopic dermatitis in adults, we must not fail to mention that, in many cases, the first phase of the dermatosis is often an infantile eczema. In other cases, three distinct phases are to be noted, namely, the dermatosis in infancy, in childhood and in the adult. These different phases may be separated by year-long intervals of complete freedom or they may continue uninterruptedly and be merged by imperceptible transition with the succeeding phase.^{6b}

The stage of atopic dermatitis that we are discussing here is a disease of early adult life. The average age of our patients at first consultation was 19 years. (It is noteworthy that we have never seen a typical case of atopic dermatitis in an individual over 50 years of

7 We have recently had occasion to discuss this entire syndrome with Drs. Francis M. Rackemann, Lewis Webb, Hill B. Thurber, Guild, Henry N. Pratt and Jacob Swartz, all of Boston. This conference brought to light a remarkable unanimity of observations and opinions. We are indebted to these gentlemen for the opportunity of obtaining this general confirmation of our point of view.

8 We do not here include migraine, gastro-intestinal allergy, allergic epilepsy, urticaria, angioneurotic edema and other questionable atopies but have considered only asthma, hay fever and allergic vasomotor rhinitis and infantile eczema.

age Even in middle age, this dermatosis is extremely rare)

The course of the dermatosis is chronic, but in the majority of cases there are remissions during which the skin may be entirely normal. Recurrences are irregular in some cases, in others they are periodic and even distinctly seasonal. Among our cases there is a large group which exacerbates regularly in the period July-September and clears up after several months, only to recur at the same season in the next year. Even during the active attacks there are often rapid variations in the severity of both subjective and objective manifestations. We have never been able to discover the causes of these fluctuations, but many patients will insist that exacerbations are unquestionably due to one or more of the following substances: (a) heat, (b) cold, (c) rapid changes of temperature, (d) perspiration, (e) certain foods, notably fish, eggs and "acid foods", (f) specific articles of clothing, such as certain silk, wool or satin garments, (g) almost all greases and greasy ointments, (h) work, worry, "strain" and "nervous upsets."

Because of the unpredictable course of this disease, we have been unable, in general, to verify the patients' statements with regard to the rôle played by the incriminated factors. We have, however, occasionally found objective evidence that the ingestion of a food (such as fish, eggs or wheat) or the wearing of a garment (such as a silk scarf or a woolen dress) has been followed by an exacerbation of a more or less quiescent atopic dermatitis. We have also noted that the appearance of a common cold was in some cases regularly followed by a flareup of the existing condition.

However, we know of no regularly successful production of the dermatosis by deliberate exposure to the presumptive causes during dermatosis-free periods. It must therefore be emphasized that, although the mass of clinical evidence suggests the rôle of exposure to certain allergens, the conclusive proof of the causal rôle of any and all of these agents is still lacking.

But the deliberate experimental exposure to allergens has not always been entirely without results. While we have never reproduced the actual atopic dermatitis, we have in some instances succeeded in eliciting other definite responses that prove skin hypersensitivity, for example, itching and urticaria after ingestion or injection of fish, and localized hives after contact with silk.

Just as it has been impossible for us to produce the dermatosis by experimental exposure, so has it also been impossible to effect a cure by the removal of suspected substances. We have noted, however, that changes of environment (home or hospital) or an intercurrent infection other than the common cold have in some cases led to a rapid clearing up of the active dermatosis. The beneficial effects of changes of environment may be due to the elimination of causal allergens, on the other hand, in some instances the benefit may be due to the removal of causes of emotional upsets.

However it is difficult to interpret the occasionally striking benefits that follow intercurrent infections as other than a nonspecific immunologic alteration.

It will suffice to mention here that precisely these two differences—change of environment and intercurrent infection—are frequently and as strikingly beneficial in asthma, hay fever and infantile eczema.

A critical analysis of the course of atopic dermatitis must lead to the one conclusion that skin hypersensitivity is a part of the producing mechanism in

some of our cases. It is evident, however, that, just as in vasomotor rhinitis and in asthma, other important factors are still entirely unknown.

DESCRIPTION OF THE DERMATOSIS

This dermatosis, not to be confused with "contact" or true eczema, has been so well described that we shall here be brief.

The outstanding symptom is itching, continuous or in crises. This itching is frequently increased by various factors, which we have already mentioned.

The primary dermatologic lesion is a papule, or a number of confluent papules forming lichenified areas. In uncomplicated cases there is no vesiculation, but there may be weeping, crusting and exudation, usually due to superimposed external irritation and infection. The lichenified plaques are not very sharply demarcated. They vary in color from a bright pinkish red to a tannish brown or a dirty grayish brown. The lichenified, thickened areas are usually surrounded by outlying, scattered and often excoriated papules.

In typical cases the distribution is characteristic and often diagnostic. The predominant localization is in the flexures—the antecubital and popliteal spaces, and the front and sides of the neck. Additional favorite sites are the eyelids, the forehead and scalp, the dorsa of the wrists, the peronychia areas of the fingers, and the dorsa of the feet. However, no skin area is immune, scattered plaques or papules are not infrequently found anywhere on the skin. In fact, severe cases may present involvement of the entire integument.

While the eruption is often symmetrical, it is never zoniform, segmentary, systematized, or in any way distributed along the course of cutaneous or other nerves.

In our experience all patients have dry skins and not infrequently even a fully developed keratosis pilaris. In fact, the follicular localization of the lichen papules may often be noted. In many patients we have observed a tendency toward cutis anserina. We have seen (in two cases) the very first manifestations of this dermatosis to be in the form of urticarial lesions, sometimes confined to the cubital and popliteal spaces.

The patients are otherwise healthy and, as mentioned previously, the average age was 19 years at the first consultation.

We do not believe that the appearance of this dermatosis can be interpreted as an argument in favor of either the psychoneurologic or the sensitization concept.

RESULTS OF INVESTIGATIVE PROCEDURES

We have employed three methods of skin testing.

1 *Scratch Tests*—In more than 50 per cent of our cases scratch tests have given positive results to various foods and environmental allergens. We wish to point out that, as a group, these patients possess the strongest and most polyvalent hypersensitivity to be encountered. (As an example, one patient, tested with 100 allergens, gave fifty-six markedly positive reactions.) However, it must be mentioned that, just as in (non-hay fever) vasomotor rhinitis and in asthma, almost 50 per cent of the clinically identical cases were negative to all scratch tests. Without wishing to draw conclusions at this point, we merely state that the majority of fall-exacerbating cases presented positive wheal reactions to ragweed pollens. We have also noted that silk elicited by far the highest percentage of strongly positive reactions. (House dust was unfortunately not included in our tests.)

2 Passive Transfer Tests—The patients giving positive reactions to scratch tests also had a high percentage of passive transfer reagins in the blood serum. We have seen as many as twenty-eight different reagins of high titer in one and the same serum. We have not been able to demonstrate that substances giving positive wheal reactions with reagins were more likely to be of clinical significance than those eliciting non-reaginic skin responses.

3 Patch Tests—In these cases, patch tests are negative. In fact, it is astonishing, in view of the apparently highly irritable skins, to find that these patients rarely react to patch tests. Not only are they far less sensitive to patch tests than are contact eczema patients, but, what is more remarkable, our patients with atopic dermatitis have been less sensitive than normal persons. There is however one exception. A fairly representative proportion of cases manifested papulopustular reactions to certain salts of heavy metals and, in particular, to nickel sulfate. This finding confirms that of Steiner.⁹ (This reaction to heavy metal salts has not yet been properly evaluated in relation to atopic dermatitis or to any other disease. However, its papulopustular nature and its course differ markedly from the usual response seen to patch test in typical eczematous hypersensitivity. These two different forms of reaction cannot, without further study and proof, be accepted as of identical significance.)

COMMENT

It seems to us that the aggregate result of the observations with these three test methods points strongly to the conclusion that the dermatosis under discussion belongs to the atopic group.

As stated before, conclusive proof is still lacking that this dermatosis is a specific skin hypersensitivity to atopens, for, to our knowledge, atopic dermatitis has not been regularly and deliberately reproduced by experimental exposure to allergens as have been asthma and hay fever. However, it seems to us that the scratch test and passive transfer results, weighed in conjunction with certain aforementioned clinical observations, constitute strong presumptive evidence in favor of the important role of specific skin hypersensitivity in the production of atopic dermatitis.

There are, of course, some authorities who will insist that the skin test and reagin manifestations are in no way related to the dermatosis, except as far as they demonstrate its association with other atopic diseases, past, present or potential. In other words, they state that the skin disease is not due to a specific skin hypersensitivity but is only associated, in some inexplicable way, with atopic diseases. This hypothesis seems tenuous. Before it can possibly be accepted it must be supported by at least as much evidence as we have adduced in support of the probable clinical importance of the skin hypersensitivity. As far as we know, no such evidence has as yet been submitted.

Our further observations in atopic dermatitis can be summarized briefly as follows. There was a moderate to marked eosinophilia in about 50 per cent of our cases. Dermographism, of either the red or the white type, was not a constant finding, but, in isolated cases, there was such marked whealing to trauma that skin testing by the direct scratch or intracutaneous method was impossible. This dermographism sometimes disappears and recurs spontaneously. Many of our cases

showed signs considered to be diagnostic of vegetative neurosis. Others showed manifestations of sympatheticotonia or of a mixed form of vegetative neurosis. The sum of the results of our investigative procedures must, in our opinion, speak in favor of the atopic nature of this dermatosis and even in favor of the clinical role of skin hypersensitivity in the production of atopic dermatitis.

THERAPY

Many therapeutic measures have been found to be more or less efficacious and their benefits to be more or less lasting. Local roentgen therapy is the sovereign remedy and often brings quick results particularly in the first few attacks. As topical applications we have found pastes and powdery lotions to be superior in general, to ointments. Resorcinol, the tars, ethyl aminobenzoate, menthol and phenol can often be employed to advantage in these vehicles. Nevertheless, certain cases become inveterate and frequently constitute the most difficult therapeutic problems. While some of these defy every therapeutic measure, we have found one or more of the following to be worthy of trial: (1) generalized ultraviolet radiation (well below the erythema dose), (2) arsenic internally, (3) sedatives (not morphine or other opium derivatives), (4) pilocarpine, ephedrine and atropine, (5) autohemotherapy, (6) calcium injections, (7) strontium bromide injections, (8) hyperpyrexia, (9) dilute hydrochloric acid by mouth, (10) nonspecific vaccine therapy (catarrhal vaccine) and (11) thyroid extract.

As previously stated, hospitalization or other change of environment sometimes produces rapid and marked improvement. Just as reported by other observers,¹⁰ we have also found that some of our patients improved when they were relieved from psychic, emotional upsets, and from the frictions and obligations of everyday life. However, this beneficial effect was no more striking than that encountered in patients with proved sensitizations, such as asthma or hay fever, or in individuals suffering from many organic (peptic ulcer, coronary disease) and even infectious diseases (tuberculosis). In our opinion it is dangerous to conclude that a disease must be psychogenic for the one reason that the psyche exerts an influence on its course.

Elimination of suspected foods, reputedly efficacious in the hands of some observers, has proved disappointing in our material. We admit that we have found great difficulty in carrying out rigid elimination diets in our ambulatory patients.

We have not been able to test the effects of elimination of air-borne allergens, as we have had no available allergen-free rooms. Since our reacting patients regularly had skin test reactions and reagins not only to foods but also, in at least equal degree, to inhalant substances, we do not believe that the significance of the positive skin tests can be properly evaluated until both suspected foods and suspected environmental allergens can be simultaneously eliminated (elimination diets while in allergen-free rooms).

We have attempted specific hyposensitization in several cases, by means of injection of the suspected atopens. This measure has been without success. But we do not consider that the failure of this method negates the existence of a specific skin hypersensitivity, for it is well known that persistent hyposensitization injections in patients with hay fever and asthma, while they often reduce the clinical hypersensitivity of the mucous membranes, do not, as a rule, accomplish a noticeable reduction in skin sensitivity.

⁹ Steiner, K. Ueber die Ergebnisse und den Wert der funktionellen Hautprüfung mittels der Lappchenprobe bei Hautkranken und bei Haut Gesunden. Arch. f. Dermat. u. Syph. 157: 600, 1929.

¹⁰ Stokes¹ and der Eric and Becker.²

It must be mentioned that atopic dermatitis not only runs an eccentric course with as yet, inexplicable exacerbations and remissions but also in most cases leads sooner or later to an equally mysterious spontaneous recovery

SUMMARY AND CONCLUSIONS

1 In a study of more than fifty cases of typical adult atopic dermatitis we could find no convincing evidence of the primary importance of psychoneurogenic factors in the production of atopic dermatitis

2 The family history, the personal history, the course and the results of investigations and therapy demonstrate that this dermatosis is closely associated with diseases of the atopic group

3 Our observations also strongly suggest that specific skin hypersensitivity is in many cases an important factor in the production of atopic dermatitis

4 There is as yet no convincing evidence that atopic dermatitis can be regularly produced by deliberate exposure to suspected allergens or that the dermatosis can be regularly ameliorated by removal of allergens

5 While the adduced evidence strongly suggests that atopic dermatitis is due in many cases to specific skin hypersensitivity, unequivocal proof is still lacking

Clinical Notes, Suggestions and New Instruments

THE USE OF PAPAVERINE IN ACUTE ARTERIAL OCCLUSIONS

GEZA DE TAKATS M.D. CHICAGO

Papaverine, an alkaloid of the opium group was first advocated for the relief of smooth muscle spasm by Professor Pal¹ of Vienna. On the basis of clinical observations backed up by animal experiments, he stated that the drug relaxes smooth muscle without paralyzing it and recommended it in hypertension in angina pectoris and for the abortion of urticarial crises. A comprehensive pharmacologic study of this drug was given by Macht.² Summing up the circulatory effects of papaverine he noted a fall in blood pressure which was due partly to the effect on the brain but chiefly to peripheral action as it produced a marked vasodilatation especially of the peripheral and splanchnic arteries. The drug increased coronary circulation, slowed the heart and at the same time increased the strength of contraction. As to its effect on respiration papaverine dilated the bronchi and diminished the rate of respiration but increased the volume output and alveolar ventilation. It did not depress the respiratory center as shown by its lively response to carbon dioxide inhalation. It relaxed all types of smooth muscle without paralyzing them. Its analgesic property could be demonstrated after the subcutaneous injection of 40 mg in man which corresponded to the effect of about 10 mg of morphine. The dose that both Pal and Macht recommended in man was not to exceed 0.06 Gm (1 grain) by mouth from 0.06 to 0.10 Gm (1 to 1½ grains) subcutaneously and from 0.01 to 0.04 Gm (one sixth to two thirds grain) intravenously.

Recently Denk³ made the significant suggestion of treating patients suffering from acute embolic occlusion with intravenous doses of papaverine. He stated that the results in ten cases were equal to those obtained by embolectomy and he felt that the results were due to a release of a vessel spasm which occurs at the time of the acute embolism and represents an additional menace to the affected part.

It has long been supposed that sudden arterial obstructions produce a reflexor vessel spasm both in the affected artery and in the collateral vascular tree. The literature containing evidence in this direction has been concisely summarized by Allen and MacLean.⁴ The most clear-cut evidence is that of Mulvihill and Harvey⁵ who found that when the external iliac arteries of dogs were ligated a drop in the temperature of the hind limbs developed which gradually subsided in an average of thirteen hours. When however, a lumbar sympathectomy was performed before the ligation, the drop in temperature did not occur. If sympathectomy was performed when the temperature had already dropped it immediately returned to normal. Thus the exclusion of the vasoconstrictor influence on the limb prevented the manifest circulatory embarrassment.

In a previous communication I⁶ referred to the use of papaverine to overcome the initial spasm of collaterals in acute vascular occlusions. Five cases are now presented.

REPORT OF CASES

CASE 1—C. H., a 42 year old, stocky, robust man, had an operation for inguinal hernia under local anesthesia, Dec 4, 1934. There followed an entirely uneventful convalescence with primary union of the wound. He was discharged from the hospital on the fourteenth day. On the fifteenth day, while sitting quietly at home reading the paper, he was suddenly seized with dyspnea and a feeling of impending death. He first became pale, then cyanotic and lost consciousness. I arrived at his home five minutes later. His pulse was barely palpable, his skin was cold and clammy, his respiration was superficial and very rapid. One-sixth grain (0.01 Gm) of papaverine hydrochloride was given intravenously. Within two minutes his pulse became slower and increased in volume. The respirations were slower and deeper. His color became normal. Subsequent portable x-ray examination revealed a triangular infarct in the right lung thus confirming the diagnosis of pulmonary embolism. He recovered completely.

CASE 2—Mrs. I. A., aged 42, referred by Dr. O. G. Schnetzer developed a fever following the extraction of four teeth with apical abscesses. April 7, 1935, she developed an arterial occlusion first in the left and later in the right limb. Both limbs were cold, pulseless, cyanotic. Pain was extreme, unrelieved by morphine. Papaverine hydrochloride (one-sixth grain) was given about eight hours later as none was available in the hospital when the patient was first seen. This seemed to relieve the pain and the color of the feet improved. She was admitted to St. Luke's Hospital next day. During the first three days, papaverine (one-sixth grain) was given twice a day intravenously which seemed to calm the extremely restless patient and enable us to place her in the negative pressure apparatus. The color of the feet gradually became normal until the tenth day after admission when another shower of emboli was thrown into first the right and then the left leg. The left foot became bluish gray and while pulsations were still present in both femoral arteries oscillations taken with Paelon's oscillogometer, were absent at the mid thigh on the left and present on the right. No pulses were felt at or below the popliteal arteries. One half grain (0.03 Gm) of papaverine hydrochloride was then administered intravenously and the observations were made that are recorded in the accompanying table.

To sum up these observations, the pulse and blood pressure dropped but not to a subnormal level. The temperature of the big toe rose although not to a level of normal vasodilatation (31° C or 87.8° F). The color of the foot improved with the exception of the second toe and the pain was relieved. In this calm, relaxed condition which was by no means the type of somnolence or sleep produced by the barbiturates, the limbs could be placed in the boots of a negative pressure apparatus and treatment could be given for half an hour, which the patient was unable to stand previous to the injection of papaverine.

⁶ de Takats Geza. Obstructive Vascular Disease. Preliminary Report on Treatment by Alternating Negative and Positive Pressure. *J. A. M. A.* 103: 1920-1924 (Dec. 22) 1934.

While the right leg was seemingly in a state of sustained circulation the color of the left foot again became worse in spite of a number of negative pressure treatments and 1 grain (0.065 Gm) doses of papaverine by mouth three times a day. The second shower obviously had plugged the origin of the profunda femoris and the patient was returned to the care of Dr O T Roberg at the Swedish Covenant Hospital. There was still no gangrene at the time of discharge but the second toe was cyanotic. At autopsy, a week after her discharge from St Luke's Hospital, thrombotic occlusions of both popliteal arteries were found, but no source of any embolism.

CASE 3—Mr C W S, a patient of Dr Donald Abbott, was seen in consultation at the Billings Memorial Hospital. The patient had a severe coronary occlusion with auricular fibrillation on June 18, 1935. Two weeks later the right foot became cold and cyanotic but gradually improved. July 6 the right femoral artery became suddenly occluded. There developed a discoloration of all toes, but especially the first and second were involved. The skin became wrinkled and began to blister. When seen thirty-six hours after the vascular occlusion there was no pulse in the pedal and popliteal arteries. The oscillographic curves were negative to the mid thigh. The histamine reaction was negative below the knee. A diagnosis of popliteal embolism with a second shower to the origin of the profunda femoris was made. Passive vascular exercises from five to seven hours a day had already been started without any apparent effect on pain or circulation. A constant temperature heat cradle was employed and papaverine hydrochloride one-fourth grain (0.016 mg) twice a day was started intravenously, which was continued for four days.

Observations in Case 2

Time	Pulse	Blood Pressure	Temperature of Toe*	Color of Foot	Subjective Symptoms
Before injection	130	140/85	27.2 C (80.9 F)	Grayish blue	Restless moaned in pain
2 minutes after	130	140/80	27.4 C (81.3 F)	Same	Same
5 minutes after	120	140/75	27.8 C (82 F)	Definitely better	Same
10 minutes after	110	110/75	28.2 C (82.7 F)	Normal except 1st and 2d toes	Calm dozing
20 minutes after	100	110/70	29 C (84.2 F)	Normal except 2d toe	Sleepy but could be aroused
30 minutes after	100	110/70	29 C (84.2 F)	Normal except 2d toe	Calm and comfortable

* Room temperature was 27.5 C (81.5 F) humidity unknown

Soon after the first injection a marked change took place in the color of the affected limb. It turned pink, the cyanosis of the toes disappeared. In order to sustain the gain in circulation, passive vascular exercise treatments were maintained for several weeks. A total of forty-one hours was given, at which time the collateral circulation was quite adequate but the pedal pulses were still absent. The histamine flares were normal throughout the extremity. On July 14 a sudden abdominal cramp was noted, which was interpreted as a mesenteric occlusion. July 16 a cerebral embolus followed by facial asymmetry and anarthria occurred. Passive vascular exercise treatments were then discontinued. July 28 another coronary occlusion was diagnosed, followed by a pericardial friction rub. The patient was transferred to his home and at this writing, two months after the vascular occlusion, the circulation of the limb was maintained outside an elliptic area of cutaneous gangrene just below the knee over the tibia, which slowly healed.

CASE 4—J V, a woman, aged 46, was seen in consultation with Dr A V Partipilo thirty hours after an acute vascular occlusion. The patient had had a chronic hyperthyroidism with auricular fibrillation and an adequately controlled diabetes. A diagnosis of an embolic occlusion at the iliac bifurcation was made. There was a complete absence of all peripheral pulses, including that of the femorals at the groin and a marked vessel spasm, which was manifest as high as the interiliac line. Both feet were cyanotic. Pain could not be controlled by morphine. Papaverine hydrochloride one-half grain (0.03 Gm.) was started

twice a day intravenously with no effect on the gangrene and only slight relief from pain. The patient refused to be hospitalized, developed a bilateral gangrene to the knee, and died eight days after the embolic occlusion.

CASE 5—W S was hospitalized in the medical service of Dr R W Keeton at the Illinois Research and Educational Hospital with the diagnosis of acute bacterial endocarditis since April 20, 1935. On May 9 he complained of excruciating pain in the left upper quadrant radiating to the shoulder, which was interpreted as a splenic infarct. July 25 a diagnosis of left popliteal embolism was made. A constant temperature heat cradle was used and sedatives were given. When he was seen thirty hours after the onset, there were no pedal and popliteal pulses, and the foot was numb, cold and cyanotic. The first and second toes showed beginning gangrene. Papaverine was started by mouth, 1 grain (0.065 Gm) three times a day, but because of some misunderstanding in the drug room intravenous injections were started July 27, approximately fifty hours after the vascular occlusion and were continued for five days. The gangrene progressed but remained dry and began to demarcate at the lower third of the leg. August 19 the patient had a left cerebral and on the 21st a brachial embolus. He died on the 22d with signs of respiratory failure.⁷

COMMENT

These five case reports would indicate that the arterial spasm accompanying an acute vascular occlusion may be relieved by an early intravenous administration of papaverine. While in the case of pulmonary embolism it seemed to act as a life saving measure (although the possibility of spontaneous recovery cannot be denied), in the case of peripheral occlusion it was possible to follow the marked subjective and objective improvement step by step. As Denk has pointed out, the extent and duration of the occlusion and the rigidity of the vessel wall may naturally set a limit to the capacity of the drug in aiding collateral circulation. He also warned of delaying embolectomy if the circulation did not rapidly improve.

In the case of Allen and MacLean there was a startling return of circulation in the right leg while in the left, in which there was a complete occlusion of the external iliac artery, the gangrene extended slowly so as to require an amputation through the upper part of the thigh. This case is especially instructive as it proves the point observed in the second and fourth patients, namely, that a complete block of the external iliac artery or any block above the profunda femoris cannot be readily compensated even if collateral spasm is released whereas, on the contrary, an occlusion distal to the profunda femoris can be easily overcome. Allen and MacLean also emphasized that the negative pressure treatments may act by inducing collateral circulation to open up more rapidly and thus interpretation was suggested by Reid⁸ in analyzing his good results in acute vascular occlusions with the intermittent negative pressure apparatus.

The importance of papaverine injections seems to lie in the fact that it is a harmless procedure. While the suction treatment or the embolectomy is naturally limited to larger medical centers this drug is available to every practitioner and may either actually tide the limb over the critical period or enable the surgeon to operate at a time at which without papaverine the limb would have been frankly gangrenous. In the second and third cases the injection was combined with an intensive use of the suction apparatus of Reid and Herrmann. The papaverine not only calmed the patients but gave a possibly maximal vasodilatation during treatment. The desirability of reducing spasm in the extremities so treated has been stressed by Landis,⁹ who employed heat for this purpose. It seems likely, however, that papaverine gives a more widespread vascular relaxation than heat could accomplish.

If papaverine is to be of any benefit it must naturally be given as soon as the diagnosis of pulmonary or peripheral embolism is made. In the fourth and fifth cases the drug was given too late to influence the early spasm. There are no stable

⁷ Recently the drug was employed in a case of popliteal thrombosis following an orthopedic operation. With the exception of a pressure sore over the achilles tendon the circulation of the foot was sustained.

⁸ Reid M R. Diagnosis and Treatment of Arteriosclerotic Peripheral Vascular Diseases. Am J Surg 24: 11 (April) 1934.

⁹ Landis E M and Gibson J H Jr. Effects of Alternating Suction and Pressure on the Blood Flow to the Lower Extremities. J Clin Investigation 12: 925 (Sept) 1933.

solutions of papaverine on the market. Papaverine, however, can be kept on hand in capsules, containing one-half grain (0.03 Gm.) of the crystals and may be readily dissolved in a 1 cc ampule of physiologic solution of sodium chloride. The solution may be quickly boiled in a spoon over a flame and the intravenous injection can be accomplished with a hypodermic needle and syringe. Slow injection is advisable. To obtain maximal benefit, the drug should be given in the first six hours, combined with controlled heat and intermittent negative pressure. Given later, the result must depend on the degree, extent and duration of organic occlusion.

The use of papaverine or its combination with controlled heat and negative pressure is by no means intended to eliminate embolectomy entirely. But very often suitable equipment and a trained surgical team are not available. Should papaverine fail an embolectomy may still be considered, but both procedures can be effective only if used within the first six or eight hours. Contrary to the aroused interest of continental and especially Swedish physicians, the medical profession at large is still hesitant to regard arterial embolism as a case of maximal urgency.

It is possible, as Allen and MacLean suggest, that coronary, cerebral, mesenteric and renal vascular occlusions will be equally amenable to such treatment. It is likely that a better drug may become available. The principle, however, of combating the reflectoric vessel spasm of acute arterial occlusions seems an important one and deserves wide recognition among the medical profession.

SUMMARY

A case of pulmonary embolism, another of acute peripheral thrombosis and three cases of peripheral embolism were seen, in some of which a striking improvement of circulation resulted following the intravenous use of papaverine. The drug is an active antispasmodic and seems harmless in the doses recommended.

A NEW SUTURING NEEDLE

O. A. NELSON, M.D., SEATTLE

The needle herein pictured was devised to facilitate and expedite the placing of interrupted sutures. Furthermore, as it uses a single strand of sutural material this needle causes less traumatism than does a conventional type of needle. The

Suturing needle. A, wheel for propelling sutural material; B, knife for cutting it.

instrument consists of a hollow needle and handle which has a wheel for propelling and a knife for cutting the sutural material. Any sized catgut, dermal or silkworm gut can be used.

Its mode of operation is very simple. When the end of sutural material has been placed under the wheel in the handle and after the needle has been passed through the tissue to be sutured, the operator, by turning the wheel, forces the sutural

material out beyond the end of the needle. Then by grasping and holding the end of the sutural material and by withdrawing the needle, the operator, by pressing the knife, can sever the sutural material at a desired length. Thus interrupted sutures can be rapidly placed even in a deep cavity.

It was through the ingenuity of Mr. D. E. Selby, 2307 Walnut Street, Seattle, that I was able to have this instrument made.

LEUKEMIA WITH THROMBOCYTOSIS

CARL B. DRAKE, M.D., ST. PAUL

An unusually high blood platelet count of more than 2,500,000 is the reason for this report.

A Scandinavian woman, aged 65, was admitted to the Ancker Hospital in March 1935 because of recurrent extensive subcutaneous hemorrhages and shortness of breath on exertion. She had been in the same hospital five months before because of the same shortness of breath. This was thought to be due to a hypertension with slight decompensation and possibly a coexisting nephritis. In November 1934 the red blood cell count being 5,800,000 and the blood platelet count 1,000,000, venesection was performed at the Ancker dispensary with some subjective relief. Following this, subcutaneous hemorrhages began to appear and on one occasion a severe epistaxis.

On examination the patient's complexion suggested a polycythemia although it was not the typical brick red color. The lips were definitely cyanotic. There were large areas of subcutaneous hemorrhage over the sacrum and left shoulder, and at the center of each area was a pale tender nodule. The vision was poor, owing to a marked myopia, and the eye backgrounds showed areas of chorioretinitis attributable to the myopia, and the veins seemed a little prominent. The superficial veins of the neck were distended and the heart was definitely enlarged. This enlargement was confirmed by roentgen examination, which showed the heart to be 68 per cent of the chest diameter. Breath sounds were present at both lung bases but the roentgenogram showed cloudiness at both these areas. The liver was moderately enlarged and increased in consistency, and the spleen was palpable two fingerbreadths below the costal border. There was slight pitting of the ankles. The radial arteries were tortuous and sclerotic. The blood pressure was 190 systolic, 118 diastolic.

During the first week in the hospital, blood examinations showed the hemoglobin ranging from 70 to 84 per cent, red blood cells 4.5 to five million with many nucleated reds, white blood cells 22,000 to 33,000 with polymorphonuclear neutrophils 82 to 92 per cent, lymphocytes 7 to 11 per cent, mononuclears 2 to 5 per cent, eosinophils 1 to 2 per cent.

Further laboratory studies showed no increase in the fragility of the red cells. The blood urea was 23 mg., creatinine 1.5 mg., blood sugar 145 mg. The coagulation time was four minutes ten seconds and the bleeding time two minutes twenty seconds, both within normal limits. The urine was of normal specific gravity, the albumin varied from none to 2 plus, hyaline casts were reported occasionally and occasional white blood cells but no reds. Urobilin and urobilinogen were not present.

An Ewald test meal showed no free hydrochloric acid and 16 combined acidity.

During the patient's five months stay in the hospital repeated blood platelet counts by the usual dilution method showed figures from 1,000,000 to 2,580,000. At first an occasional megakaryocyte was the only abnormal white cell found. Toward the end of her stay in the hospital however the differential leukocyte count showed polymorphonuclear neutrophils 72 per cent, immature polymorphonuclear neutrophils 9, leukoblasts 4, stem cells 1, eosinophils 4, immature eosinophils 1 and lymphocytes 8 per cent.

Biopsy of a hemorrhagic nodule showed an organizing clot but no thrombosed vessel. Oozing and even brisk bleeding at the site of the biopsy lasted twenty-four hours and was quite distressing. For this reason a contemplated sternal puncture

was not carried out. Following the bleeding the erythrocyte count fell to 4,450,000 but subsequently returned to 5,440,000.

While the patient was in the hospital a strangulated femoral hernia necessitated operation, at which excessive bleeding was not encountered. Another severe epistaxis occurred while the patient was in the hospital and hematemesis of fresh and old blood following the biopsy.

COMMENT

The megakaryocytes have been definitely established as the source of the blood platelets. The number of platelets in the blood and megakaryocytes in the bone marrow usually correspond in conditions in which either is increased or decreased. Platelets have been found to be moderately increased following hemorrhage, in Hodgkin's disease and in chronic myelogenous leukemia. Increase has also been reported following liver therapy.

The platelet seems essential to coagulation but the platelet count is not an index of the coagulability of blood. Spontaneous hemorrhages do occur in the presence of high platelet counts, as in the case here presented.

A blood platelet count over 2 million seems to be rare. Epstein and Kretz¹ in 1930 reported a case in many respects resembling this one with a platelet count of 2,220,000 and an erythrocyte count ranging from 55 to 65 million, the leukocyte count being from 10,000 to 15,000 without evidence of leukemia. The bleeding time was increased (finger two minutes fifty seconds, ear, five minutes) and she had some bleeding of the gums and excessive bleeding following a tooth extraction which reduced the red blood cells to 3,800,000 and platelets to 800,000. In two years the erythrocyte count had returned to 5,400,000 and the platelets to over a million. The clotting time was not increased. These authors state that the only disease in which the blood platelets are greatly increased is erythremia and that several cases have been reported with counts of 700,000 and 800,000, also that the megakaryocytes have been found increased in the bone marrow in erythremia. They found that their patient had the most extraordinary and persistent platelet count encountered in the literature. They felt that the high red cell count warranted their classifying their case as an erythremia although the tendency to bleeding and headaches were not consistent with a typical erythremia. They were inclined to believe that their case represented a hitherto unknown disturbance of the bone marrow, which might be called a thrombocythemia. Later in the same year (1930) and the same journal Bode with reference to Epstein and Kretz's case mentioned a monograph by Weber and Bode on erythremia in which had been mentioned a disturbance of the bone marrow with megakaryocytes and platelets in the blood analogous to erythremia and leukemia.

Minot and Buckman² in an article on blood platelets report that platelets in seven of thirty-five cases of chronic myelogenous leukemia were persistently excessive ranging from 800,000 to 2,000,000, and that petechiae and even frank hemorrhages occurred even when the blood platelet count was high. Their experience was that the platelet count is low in the lymphatic type of chronic leukemia.

In another article, Minot³ called attention to the fact that megakaryocytes are found in the peripheral circulation and occasionally in large numbers. He had found them in myelogenous leukemia and in two cases of polycythemia vera and one of Hodgkin's disease. In one case of myelogenous leukemia, the megakaryocytes were present in the blood but no increase in platelets was found.

Downey says that megakaryocytes and increase in blood platelets can occur in polycythemia.

When the patient was first seen, the diagnosis in this case presented some difficulty. The blood platelets, red cells and myelocytes all being derived from the myeloblasts and the

blood picture showing an overproduction of platelets, red and white cells, the platelets showing the greatest increase, the question arose whether or not the condition was a new entity that could be called "thrombocythemia," a blood dyscrasia analogous to erythremia but distinct from leukemia, or should a case presenting this blood picture when first encountered be diagnosed megakaryocytic leukemia. The later appearance of premature white cells justified the diagnosis of myelogenous leukemia, a grave prognosis and the expectation of the development in time of the usual coexisting anemia. The clinical picture too, with subcutaneous hemorrhages, epistaxis and enlarged spleen and liver, is consistent with the diagnosis of leukemia. If observed long enough may not those other rare cases with very high platelet count, but no early white cells in the circulation, prove to be leukemia?

1235 Lowry Medical Arts Building

AUDITORY NERVE INVOLVEMENT AFTER TETANUS ANTITOXIN FIRST REPORTED CASE

RICHARD D. CUTTER, M.D., SAN FRANCISCO

A survey of the literature of toxic neuritis of various nerves due to the administration of tetanus antitoxin fails to reveal any report of involvement of the eighth cranial nerve. The following case is therefore of interest.

M. B., a white schoolboy, aged 14, admitted to the children's ward of Lane Hospital, Sept. 22, 1935, complained of irrationality and deafness occurring one week after the administration of tetanus antitoxin. The boy had always been in good health. About four and one-half weeks before admission he had stepped on a rusty nail in the barnyard. The wound was untreated, except for the application of iodine, and healed readily. Three weeks later he visited a physician because of twitchings in various muscle groups for one day and inability to open his jaw. Within a period of forty-eight hours he was given a total of 125,000 units of tetanus antitoxin intramuscularly, intravenously and intraspinally; the twitching subsided. Five days later (September 17) he was given an additional 1500 units of the antitoxin into the right pectoral muscle and a severe local reaction followed. During the next few days he complained of increasing deafness, noises in the ears and double vision. His neck became rigid, he was irrational at times and finally an itching urticarial rash developed.

At the time of admission he was seen to be very well developed with evidence of recent weight loss, weakness and exhaustion. The rectal temperature was 38 C (100.4 F). There was definite impairment of hearing. The jaw opened fully and the neck was not stiff. The region of the right pectoral muscle was reddened, tense and tender and there was marked limitation of motion of the right shoulder with weakness of the right arm. The original puncture wound caused by the rusty nail was entirely healed.

The blood count showed 5,990,000 red blood cells, hemoglobin 105 per cent (Sahli), 9100 white blood cells with 50 per cent polymorphonuclear leukocytes, 30 per cent lymphocytes and 18 per cent eosinophils. The urine showed a trace of albumin. Examination of the stool was negative. The blood Wassermann reaction was negative.

An audiogram, September 23, showed approximately 40 per cent loss of hearing for speech on the right and approximately 50 per cent loss on the left. The temperature promptly fell to normal and during one week in the hospital the swelling and tenderness of the right pectoral region decreased markedly and the right arm regained its normal strength. The deafness increased, however, and on September 26 the loss of hearing was 61 per cent on the right and 69 per cent on the left. The patient complained of bilateral tinnitus throughout his hospital stay.

He returned to his home, September 28, and was not seen again until November 7, at which time he was subjectively well and stated that the tinnitus and deafness had disappeared.

From the Department of Pediatrics, Stanford University School of Medicine.

2. Minot, G. R. and Buckman, T. E. The Blood Platelets in the Leukemias. Am. J. M. Sc. 169: 477 (April), 1925.

3. Minot, G. R. Megakaryocytes in the Peripheral Circulation. J. Exper. Med. 36: 1 (July), 1922.

Audiograms revealed a loss of hearing of approximately 9 per cent in the right ear and of approximately 21 per cent in the left.

Doyle,¹ in tabulating forty-nine cases of neurologic complications of serum sickness, found that the brachial plexus was more frequently involved than any other portion of the nervous system. Next in frequency were neuritis of the radial nerve and optic neuritis. In the literature surveyed, none of the reports of neurologic accidents following administration of various antitoxins mentioned involvement of the eighth cranial nerve.

In the present case the occurrence of marked deafness during the course of serum sickness and subsequent recovery of almost normal hearing seem quite definitely to establish the diagnosis as nerve deafness due to the administration of tetanus antitoxin.

The transient weakness of the right arm during the course of the patient's illness might be interpreted as an involvement of the brachial plexus on the right due to serum administration but it seems more likely to have been a pseudoparalysis due to pain and tenderness at the site of the serum injection in the right pectoral region since the normal strength of the arm returned as the pectoral pain and swelling subsided.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS

HOWARD A. CARTER, Secretary

ANNUAL MEETING OF THE COUNCIL ON PHYSICAL THERAPY

The tenth annual meeting of the Council on Physical Therapy since it began to function was held at the Palmer House on Friday and Saturday, January 10 and 11. Dr. Harry E. Mock, Chicago, was reelected chairman and Dr. Frederick J. Gaenslen, Milwaukee, vice chairman.

A report was given of the work being done with the aid of research grants. Several recipients have published reports of their investigations. Recommendations were made as to types of research which the Council thought advisable to encourage during 1936. Applications for grants are available by writing to the secretary of the Council.

Postgraduate and undergraduate instruction in physical therapy was discussed. It was believed that one of the most feasible ways as demonstrated during the past years to acquaint the general practitioner with the simpler forms of physical therapy was through the medium of city, county and state medical meetings. Consultants on education and the Council's Committee on Education with its educational program. Consultants elected for 1936 are Drs. Bernard Fantus, Chicago; A. J. Kotkin, St. Louis; Richard Kovacs, New York, and Franklin P. Lowry, Newton, Mass.

Among the problems considered by the Council were the investigation of orthopedic appliances, shoes and posture equipment; the consideration of radium and radon compounds; the problem of a seal of acceptance; and the investigation of short wave machines.

When considering short wave machines submitted to the Council for investigation it was found that several machines would heat the deep lying tissues as well as conventional diathermy, only if cuff electrodes were used and that the pad electrodes were not as efficient. Therefore it was thought best to require that the manufacturer of these machines (accepted solely on the basis of their performance with cuff electrodes) furnish cuff electrodes as standard equipment and the manufacturers have expressed their willingness to comply. Several manufacturers furnish air spaced electrodes with their machines but so far no manufacturer has submitted conclusive evidence that these electrodes are efficacious.

In the investigation of spectacle lenses and ophthalmologic devices, the Council has been assisted by the Committee on Standardization and Drugs of the Section on Ophthalmology of the American Medical Association and a report of the work was submitted by that committee.

It was reported that the revised, second edition of the Handbook of Physical Therapy will be printed in a short time, and that the pamphlet Apparatus Accepted will be brought to date later.

ACOUSTICON ACCEPTABLE

Manufacturer: Dictograph Products Company, Inc., New York.

The manufacturer states that the Acousticon is "an electrical device suitable for use by an individual whose hearing efficiency has been lowered appreciably. It constitutes a method of reinforcing by electrical amplification sound energy which is normally too weak to permit audition."

It is made in such a form that it can be carried on the person and it is adjustable to the momentary needs of the user. Its source of electrical energy is dry cell batteries enclosed in a sealed container.

Fundamentally the instrument consists of a transmitter constructed not unlike a telephone transmitter, so that it responds to very weak sounds, reproducing them with reinforcement in certain tone ranges. Each model transmitter has a maximum reinforcement in different tone ranges. This microphone is connected by light electrical cordage to the battery and also to a receiver. Two fundamental types of receivers are supplied, the conventional air conduction and bone conduction. The air conduction receivers are made in two sizes, regular and midget, the latter being fitted with a molded insert which fits the recess of the external ear, projecting slightly into the canal. These molded pieces are fastened to the receiver with a snap connector making easy removal for cleaning possible.

Acousticon

In some models of the Acousticon an amplifying device is used between the microphone and the receiver which intensifies the electrical impulses generated by the microphone delivering to the receiver a substantially increased electrical signal.

The volume response characteristic for tones throughout the range of speech frequencies is different in each instrument model. This characteristic is determined almost entirely by the transmitter and ear piece combination and can be adjusted by such combination to suit the requirements for satisfactory audition by various individuals. Instrument combinations provide different degrees of amplification in the essential portions of the tone range.

All metal on the exterior of the instrument is suitably japanned or finished to eliminate any effect on the skin of the user, and all nonmetallic parts are of molded bakelite, rubber and silk.

Hearing aids are usually of considerable aid in cases of middle ear or conduction apparatus impairment. However, when there is marked impairment of the auditory nerve or perception apparatus, the assistance derived varies according to the individual condition and in extreme cases no benefit is gained.

The unit was tested under actual conditions by an investigator selected by the Council and was found to be generally satisfactory.

The special batteries used with this unit are distributed solely by the firm. The Council feels that the manufacturer would serve the hard of hearing better by adopting this unit to standard flashlight batteries which could be accomplished by supplying a case to hold standard flashlight cells for it believes it is more important to be able to replace the batteries readily and cheaply than to have special batteries giving slightly longer service which are not often quickly obtainable. Furthermore in the case of special hearing-aid batteries, the Council feels that

the battery terminals should be standardized so that a battery, no matter where purchased, will fit all makes of hearing aids.

When these devices are prescribed, in the opinion of the Council, the Company should permit the patient to try them and be certain that they will fit his specific type of deafness under the particular circumstances in which he is most desirous of aid.

In view of the results of the investigation of this unit, the Council voted to include the Acousticon in its list of accepted devices.

UNIVERSAL BOVIE UNIT ACCEPTABLE

Manufacturer The Liebel-Flarsheim Company Cincinnati

This unit is designed for electrosurgery and for medical diathermy. It is a spark gap type and is equipped with a selector switch, multiple connections for operating instruments and sterilizable control handles. Its shipping weight is unit 111 pounds subcabinet 69 pounds. This unit is claimed to be ground free and shock proof. All currents pass through a special filter circuit designed to eliminate the possibility of faradic or other shocking currents being transmitted to patient or operator. Its frequency is approximately 1,000,000 cycles per second (wavelength 300 meters). The power required to operate the unit at full load is about 390 watts. Figure 2 is a diagram of the circuit.

Fig 1—Universal Bovie Unit

The manufacturer submitted evidence pertaining to the electrical and physical characteristics of the unit. The data indicated that the temperature rises of the transformer and spark gap after a run at full load for one hour were within the limits adopted by the Council. The Council's investigator reported that the unit was well made and that good material appeared to have been used in its manufacture.

Fig 2—Schematic diagram of the circuit

The performance of the apparatus was satisfactory when used for seven months in a clinic acceptable to the Council.

In view of the favorable report of the investigator, the Council on Physical Therapy voted to include the Universal Bovie Unit in its list of accepted devices.

EDMANDS ELECTRIC BAKER ACCEPTABLE

Manufacturer Walter S Edmands, 135 Columbus Avenue, Boston

This heating unit is a useful and simple method for applying heat therapeutically to the body.

It consists of a number of incandescent lamps so wired and controlled as to produce three different degrees of heat. The lamps are spread under two curved aluminum reflectors, which are hinged together. The device may be adjusted so that it may fit around an arm or a leg and the larger sizes will fit around a back. From six to twenty-four 60 watt lamps operate on either alternating or direct current. The shipping weight varies according to size, from 10½ to 50 pounds.

Edmands Electric Baker

One model of the Edmands Electric Baker was tried out in an acceptable clinic and found to be satisfactory for the application of local heat to the extremities. The device seems well suited for the maintenance of luminous and heat radiation of maximum tolerance around curved body surfaces, such as an arm or a leg.

In view of the favorable report, the Council on Physical Therapy voted to include the Edmands Electric Baker in its list of accepted devices.

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING STATEMENT AND REPORT

PAUL NICHOLAS LEECH Secretary

THE NEW ERGOT ALKALOID "ERGONOVINE"

During the past year, communications from four laboratories have been published reporting the isolation of a new oxytocic alkaloid from ergot. Until recently there has been doubt as to whether or not the principles reported by these laboratories were identical (termed 'Ergotocin' by Kharasch, 'Ergometrine' by Dudley and Moir, 'Ergobasine' by Stoll, and 'Ergostetrine' by Thompson). In a jointly signed statement (*Science* February 28) Kharasch, King (acting for Dudley), Stoll and Thompson say there is 'no doubt that the alkaloid obtained in the four different laboratories was the same substance.'

It is necessary, therefore, that a suitable nonproprietary name which is not therapeutically suggestive be adopted for the new alkaloid. Not one of the several names that have been proposed by the discoverers complies with these requirements. The Council on Pharmacy and Chemistry of the American Medical Association, in session March 14, therefore determined to adopt the new, nonproprietary, name 'Ergonovine' (ergo nov ine). The Council concedes to the discoverer of a product the right to the use of a proprietary name. It cannot, however, accept more than one proprietary name because of the confusion to which such practice gives rise. In the present case several different names have been proposed. It seems impossible to establish undisputed priority. The Council has decided therefore that it would recognize no proprietary name.

AMPOULE CALCIUM CHLORIDE 10% (LAKESIDE LABORATORIES, INC.) OMITTED FROM N N R

In 1929 the Council placed Ampoule Calcium Chloride 10% (Lakeside Laboratories, Inc.) on the list of 'Exempted Medical Articles' as being a pharmacopoeial article marketed under a descriptive, nonproprietary name with well established therapeutic claims. In 1932 the name of this list was changed to "List of Articles and Brands Accepted By the Council But Not

Described in N N R" The product was reaccepted for inclusion in this list in 1933

The second period of acceptance expired with the close of 1935 and, in accordance with its usual custom, the Council considered the eligibility of this product for continued recognition. In view of the fact that a less irritant calcium preparation such as calcium gluconate is now available, it was questioned whether the Council should continue recognition of so concentrated a solution of the admittedly irritant and, in the hands of the unskilful, possibly dangerous calcium chloride for intravenous use.

After due consideration the Council voted to omit Ampoule Calcium Chloride 10% (Lakeside Laboratories, Inc.) from the List of Articles and Brands Accepted By the Council But Not Described in N N R

Committee on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

FRANKLIN C BING, Secretary

ADVERTISING LEAFLET 'MEL-O-TOSE NO 1 WHAT IS IT? AND WHAT IS IT GOOD FOR?'

Sponsor—Food Concentrates, Inc., New York

Advertising leaflet for distribution to physicians containing analysis of Mel-O-Tose No 1 and formulas for Mel O-Tose Nos 2, 3 and 4, and discussing nutritional and therapeutic values of dried ripe banana

SOLITAIRE BRAND GRAPE JUICE

Distributor—The Morey Mercantile Company, Denver

Manufacturer—Church Grape Juice Company, Kennewick, Wash

Description—Bottled, processed Concord grape juice, the same as Church's Concord Grape Juice (THE JOURNAL, Aug 10, 1935, p 437)

ADVERTISING BOOKLET FOR OCEAN CLEAR LOBSTERS

Illustrated booklet prepared by S A Conover Company, Boston advertising agency, for the Consolidated Lobster Company, Gloucester, Mass, descriptive of conditions under which Ocean Clear Live Lobsters are caught stored and shipped. Contains brief statement of the nutritive value of lobsters, directions for handling live lobsters and recipes for lobster dishes

PEARLS OF WHEAT

Manufacturer—Albers Brothers Milling Company, Seattle

Description—Wheat flour middlings or farina containing from 15 to 2 per cent of wheat germ

Manufacture—Wheat flour middlings containing from 15 to 2 per cent of wheat germ is bolted, heated to destroy any insect infestation and packaged

Analysis (submitted by manufacturer)

	per cent
Moisture	90
Ash	05
Fat (ether extraction method)	13
Protein (N X 5.7)	82

Carbohydrates other than crude fiber (by difference)	80.6
Wheat germ content (germ picked out by hand)	15 to 2

Calories—37 per gram 105 per ounce

Claims of Manufacturer—A breakfast cereal For infant feeding under the direction of a physician

CARNATION YEAR BOOK OF MENUS AND RECIPES

Sponsor—Carnation Company, Milwaukee

Description—Advertising booklet prepared by the Erwin, Wasey and Company advertising agency. A recipe book containing brief statements of food value of Carnation Milk and special advantages for use in infant feeding. The menus and recipes are arranged with reference to foods available at different seasons of the year

ABSOPURE BRAND CALIFORNIA ORANGE JUICE

Manufacturer—Absopure Fruit Products, Inc., Anaheim, Calif

Description—Canned flash-pasteurized California Valencia orange juice practically equivalent to fresh orange juice in vitamin C content

Manufacture—Tree ripened Valencia oranges are washed, inspected for removal of inferior or defective fruit, and automatically halved and reamed. The juice is screened to remove seeds and coarse pulp, passed through a 'finisher' to remove everything but the finest pulp flash-pasteurized at 71 C for from two to three minutes, filled hot into enamel-lined cans sealed, and heat processed for from three to five minutes. The trees are not sprayed with arsenical sprays

Vitamin—Vitamin C—Chemical titration shows the canned product to be practically equivalent in cevitamic acid (ascorbic acid) to fresh juice

Claims of Manufacturer—Practically equivalent to fresh orange juice in vitamin C content. For all dietary and table uses

AMERICAN LADY BRAND APPLE SAUCE TOPMOST BRAND APPLE SAUCE

Distributor—General Grocer Company, St Louis

Packer—Lyndonville Canning Company, Inc., Lyndonville, N Y

Description—Canned apple sauce prepared from peeled and cored apples with added sucrose. The same as VB (Visscher Brothers) Old Fashioned Apple Sauce (THE JOURNAL, Aug 6, 1932, p 476)

ALLSWEET BRAND OLEOMARGARINE (CONTAINS 1/10 OF 1% OF BENZOATE OF SODA)

Manufacturer—Swift & Company, Chicago

Description—Margarine prepared from oleo oil, skim milk, neutral lard, peanut or cottonseed oil, salt and sodium benzoate 0.1 per cent, or hydrogenated cottonseed oil, skim milk, cottonseed oil, salt, oleo oil and sodium benzoate 0.1 per cent, or hydrogenated cottonseed oil skim milk, cottonseed oil, salt and sodium benzoate 0.1 per cent

Manufacture—The fats and oils are melted and churned with pasteurized cultured skim milk. The resulting emulsion is solidified by chilling, allowed to stand for sixteen hours at 21 C for the development of flavor, salt is worked in and excess moisture removed. The margarine is either packed in tubs or moulded into blocks and automatically wrapped and packed in cartons

SATURDAY, MARCH 21, 1936

ERYSIPELAS

In a survey of the hospital records of 1 400 patients with erysipelas, Kiefer and Spink¹ found the general mortality to be 16.4 ± 3.6 per cent. The mortality varied from year to year between 9.3 and 21 per cent. When the records were studied for factors that might account for the yearly fluctuations, it was found that the age of the patient, the presence of debilitating diseases and the occurrence of bacteremia were important. Thus the death rate is exceedingly high during the first two years of life, after that period the mortality is low until after the fifth decade when there is a rapid increase. Almost any debilitating disease, it seemed, may be an important contributing factor in erysipelas. In a series of thirty patients recently studied, all of whom recovered, bacteremia was observed only once. In another group of thirty-nine fatal cases, bacteremia was present in thirty-one before death. The yearly variation in mortality could therefore be explained for the most part on the basis of the variation in these three factors.

As a part of an investigation of the various serologic reactions that occur during and after hemolytic streptococcus infections, Spink and Kiefer² studied thirty patients with erysipelas. They investigated the antistreptolysins (antihemolysins), antifibrinolysin and streptococcal power of the whole defibrinated blood. In addition, the complement of the blood serum was titrated, agglutination reactions against the organism derived from the patient and the skin reactions to "Dick" toxin and streptococcus nucleoprotein were investigated. All the patients were studied while they were under observation in the Boston City Hospital. After the illness had subsided and after discharge from the hospital the patients were followed for periods of from one to eight months. B hemolytic streptococci

were isolated from all the patients studied. When it was not possible to obtain the organisms directly from the lesion, they could be obtained from the nasal secretions.

The antistreptolysin titer of the blood serum was determined by the method of Todd. The titer was found increased during the course of the disease and frequently remained above the original titer for periods of from forty days to six months. The highest titer was usually reached within the first twenty days after the onset of the illness. The method of Fillett and Garner was used in testing for antifibrinolysin. Twenty-five of the thirty patients developed maximum resistance to fibrinolysin within five to fourteen days of the illness. Once the resistance appeared, it persisted for periods varying from eight to 150 days. While there was no precise correlation between the appearance of maximum resistance and recovery, Spink and Kiefer considered this reaction a response on the part of the host to streptococcal infection. The streptococcal action was studied in the whole defibrinated blood by the method of Todd. During the course of the disease, the streptococcal power may be increased or remain stationary. Increases in killing power, however, could not be correlated with recovery. The titer of the complement of the patient's blood serum was determined at different times during the course of the disease. This was done by adding different amounts of the patient's blood serum to 0.5 cc of sensitized sheep cells and placing the mixture in a water bath at 37 C for an hour. The smallest amount of serum that was required to effect complete hemolysis of 0.5 cc of sheep cells was taken as the amount of complement present. The results of these tests varied widely. In general, however, there was an adequate amount of complement present for phagocytosis. Also skin tests were performed. Only one of the thirty patients reacted positively to Dick toxin although twenty-four showed positive reactions to 0.1 mg of the nucleoprotein of hemolytic streptococcus. Three patients developed agglutinins against their own organisms in titers varying from 1:40 to 1:80. Two of the three patients had suppurative complications.

In view of the multiple serologic reactions demonstrable in patients with hemolytic streptococcus infection, it is difficult to decide which responses are the more important in bringing about recovery. Recovery probably results from a summation of a variety of responses that are capable of keeping the infectious process localized and destroying or limiting the growth of the organisms in the tissues. Of these reactions, according to Spink and Kiefer, the presence of antibodies that aid in the phagocytosis and destruction of the organism seem to be of the greatest importance. The complex nature of the problem of immunity and recovery in a streptococcal infection such as erysipelas is well illustrated by these contributions.

PSYCHOGENIC FACTOR IN ASTHMA

There are certain cases of asthma, Strauss¹ says, which for various reasons (e g, the mode and age of onset or the inability to demonstrate sensitivity to any special allergens) appear to be predominantly psychogenic in the sense of "complex determined." With this view scarcely any one will disagree especially when qualified by repeated emphasis of the fact that one cannot talk correctly about "true asthma" and "psychogenic asthma," implying thereby that psychic mechanisms play no part in one and are solely causal in the other. An attempt to evaluate the psychogenic factor has, however, been begun at Guy's Hospital and is the subject of two recent preliminary reports.

In the report by Rogerson² and his co-workers it was shown that, when patients with this symptom complex and their environment were considered from the psychiatric point of view a number of interesting facts emerged which showed that the psychologic quality of the environment was just as important to these children as its physical components. The patients referred for psychologic investigation were predominantly children. Some were asthmatic without skin symptoms, some showed both asthma and prurigo-eczema, while in one or two cases the skin condition was the point of emphasis.

The intelligence of the group was above the average not only for the hospital class but for the general population. The position in the family was striking. Of the group of twenty-three children seven were the only child, six were the eldest child while four were the first boy in the family. Partly on this account and partly because of other factors a large proportion of the children had to contend with a difficult environment. No less than seventeen of the children were fussed and overprotected by their parents to a pathologic degree. This abnormality was so great that one might feel that if these children had not been brought to the hospital with asthma or prurigo they might easily have been referred on account of the nervousness engendered in them by their situation. By comparison in only two of the cases was the difficulty primarily one of jealousy of a younger child, normally another common cause for nervousness in child guidance practice.

The most interesting feature of these cases taken as a group was their uniformity of behavior. It was both overanxious and insecure and was shown by the majority of the children. This was often reflected in the personality of the parents which in many cases resembled that of the children in being overanxious and insecure and which might therefore be expected to arouse a similar response in the children.

Strauss feels that the children fall into two groups (1) children who have been very much 'wanted' by

their parents (only children, the first boy to be born in a family of girls, or vice versa and so on), and (2) "unwanted" children whose parents are overcompensating for their secret (possibly unconscious) emotional disposition to the child by fussiness and spoiling. He then considers two possible "causes" of asthma that in which the asthmatic attack is to be regarded as crudely purposive in character and that in which the asthmatic attack is infantile-libidinally determined in the strict Freudian sense. The following questions have therefore to be decided: 1. 'Is asthma crudely a purposive hysteria, in the sense of its being an attempt to solve a current conflict by neurotic means?' 2. Is asthma in a more subtle sense complex or libidinally determined? 3. Is asthma to be regarded as representing a disturbance at a 'psychoid' rather than a 'psychic' level? 4. Is an asthmatic attack to be regarded primarily as the perverted end result of a chain of conditioned reflexes? 5. Do distorted, emotionally colored fantasies of respiratory functions combine with the allergic diathesis to produce asthma?' Apparently the answers to these five questions are most likely to be forthcoming if young asthmatic children are selected for research purposes, and the best method of investigation centers around observation of their play. It is probably not only in play, however, that a child can realize its preconscious and subconscious mental life and psychoid processes in a manner that may become clear to itself and to an unbiased but trained observer. Further investigation of the asthma problem seems to require a "play technique" that takes stock of extremist points of view.

The fascinating and important studies begun in the work reported in these two papers should, at the least, lead to much better understanding of some factors in the asthma-prurigo syndrome which are so frequently found baffling.

NUTRITIONAL SIGNIFICANCE OF ZINC

More than twenty years ago, in one of their classic papers on the relation of growth to the chemical constituents of the diet, Osborne and Mendel¹ wrote "The animal cells need for their activities not only energy but also suitable constructive materials to replace the wear and tear therein. Furthermore, the cells are concerned in the elaboration of a great diversity of complex and little understood substances such as enzymes, products of internal secretion, etc., which unquestionably play an indispensable role in life and may require either special antecedent products for their construction chemical activators of some sort, or minute quantities of readily overlooked rarer elements and compounds." These pioneer studies indicated that much better growth was obtained in the experimental animals when traces of iodine, manganese, fluorine and aluminum were added to the artificial salt mixture originally made to resemble the ash content of milk.

¹ Strauss F B. The Psychogenic Factor in Asthma. Guy's Hosp Rep. 85: 309 (July) 1935.

² Rogerson C H, Hardcastle D H and Duguid K. A Psychologic Approach to the Problem of Asthma and the Asthma-Eczema-Prurigo Syndrome. Guy's Hosp Rep. 85: 289 (July) 1935.

¹ Osborne T B and Mendel L B. J Biol Chem. 15: 311 1913.

The importance of these investigations was not immediately recognized but the striking demonstration a short time later of the efficacy of small quantities of iodine in the prevention and cure of endemic goiter served to emphasize the need for adequate knowledge regarding the indispensability or even the minimum requirement of any of the inorganic constituents of the dietary. Investigators of the past fifteen years have demonstrated the undisputed importance of mineral elements in the diet. Copper, iron, magnesium, calcium and phosphorus are among the minerals that have been established as being of definite nutritional significance.

The efforts to secure undisputed evidence for the nutritional role of any particular element are attended with much experimental difficulty. This is particularly true when the mineral in question may be required by the animal in only small amounts, the experimental approach, therefore, involves the removal from the diet of every possible trace of the element to be studied. This technic has proved extremely difficult and laborious in some instances, and development of definite knowledge of the possible role of many of the elements in nutrition has awaited the refinement of laboratory procedures. This fact is aptly illustrated by the available information regarding zinc in nutrition.

In 1927 Hubbell and Mendel² reported a careful study of the zinc content of some common foods, of the effect of the metal on the growth of white mice, and of the relation of the zinc content of mice to their diet. These investigations definitely supported earlier results which demonstrated that zinc is commonly present in small amounts in foods of both plant and animal origin. A zinc-low ration was prepared which permitted the ingestion of only 0.005 mg. of zinc by each animal daily. The growth of mice on this diet was slightly retarded when compared to that of control animals. More striking evidence for a possible significant role of zinc in nutrition was obtained by the favorable effects exerted by small amounts of zinc sulfate added to the zinc-low ration. The results were not definitely conclusive but there appeared to be a slight stimulation in growth evidenced in animals receiving the zinc supplements. It seemed not unlikely that there is some variation in growth with varying amounts of zinc and that the metal is not merely an accidental factor in the nutrition of the mouse. Adequate confirmation of this suggestion is now available from two laboratories.

Investigators at the University of Wisconsin³ have made careful studies of the indispensability of zinc in the nutrition of the rat. By special refinements in technic it was possible to reduce the zinc intake to a level at which the lack of this element was manifested by a definite retardation in growth and a regular interference with the development of a normal coat of hair.

Both these unfavorable conditions could be alleviated by the addition of small amounts of a zinc salt to the purified ration. The supplement inaugurated a resumption of normal growth rate and a restoration of the thin woolly hair coat to normal. This demonstrated importance of zinc in nutrition is amply confirmed in another species by the studies of Bertrand and Bhattacharjee⁴ in Paris. Working with a ration slightly lower in zinc content than that of Hubbell and Mendel, the French investigators have demonstrated that mice placed on a synthetic diet containing less than 0.5 mg. of zinc per kilogram died in from fourteen to twenty-three days. Control litter mates ingesting a similar diet supplemented to the extent of 20 parts per million of zinc lived from fifty-seven to seventy-four days. The preponderance of evidence, therefore, indicates that zinc is an essential element in the nutrition of the rat and the mouse. Although experiments have not been conducted with other animals, it seems possible that zinc plays an important part in the nutrition of all animals. It is hardly necessary to point out that the difficulties encountered in preparing a zinc-free ration suggest that most natural diets contain sufficient amounts of this element. However, it is only by a virtually complete elimination of substances normally necessary in minute amounts in the diet that correct evaluation of their function can be obtained. Although the manner in which zinc affects the body is still unknown, the establishment of its essential nature stimulates investigations designed to determine the manner in which the element may function. The interesting observation of Scott⁵ that his highly purified crystalline insulin contains traces of zinc firmly bound in the hormone molecule are suggestive at this time, even though a definite interpretation cannot yet be made.

Current Comment

"ERGONOVINE"

Last year the isolation of a new alkaloid from ergot was reported within a relatively short period from four different laboratories, two in the United States, one in England and one in Switzerland. The new substance was found in each case to be different in its properties from the previously known alkaloids of ergot, its oxytocic effects were much more prompt and more lasting than those of ergotoxine or ergotamine and the required dosage was smaller. Some discrepancies in the reported physical and chemical properties of the material isolated by the different investigators led to doubt as to the identity of the four products, four names were proposed, ergometrine (Dudley and Moir), ergotocin (Khairasch and Legault), ergobasine (Stoll and Burckhardt) and ergostetrine (Thompson). Owing to the confusion entailed by the doubt as to the identity of the four products so designated, workers in the four laboratories commendably agreed to exchange

specimens and to compare the various products Kharasch, King (acting for the late Dr Dudley), Stoll and Thompson¹ have now reported that their "comparisons of the melting points and mixed melting points of the four alkaloids and of certain of their salts, and of their optical activities in different solvents in cases where sufficient material was available, leave [them] in no doubt that the material obtained in the four different laboratories was the same substance, and that the four names given to it are synonyms." Elsewhere in this issue (page 1008) the Council on Pharmacy and Chemistry reports the adoption at its annual session on March 14 of a new nonproprietary name for this alkaloid, "ergonovine." This new term was chosen instead of one of those already proposed because of the difficulty of determining priority and because of possible conflict of the other names with the policy of the Council governing nomenclature. The agreement among the investigators concerned as to the identity of the alkaloid and the adoption of a single name to replace the four previously in use (and others employed in addition by commercial firms) should now prevent further confusion.

Association News

THE KANSAS CITY SESSION

Distinguished Foreign Guests

Among the distinguished physicians from other countries who will attend the annual session of the American Medical Association to be held in Kansas City Mo. are Lord Horder of Ashford London, England, Dr Afranio do Amaral of Instituto Butantan, São Paulo, Brazil and Dr Francisco Miranda Mexico City, Mexico.

Lord Horder and Dr Amaral will take part in the program of the General Scientific Meetings on Tuesday, May 12. Lord Horder and Dr Miranda will each present a paper before the Section on Practice of Medicine.

RADIO BROADCASTS

The American Medical Association broadcasts over WEAf, the Red network instead of the Blue as formerly, and certain additional stations of the National Broadcasting Company at 5 p. m. eastern standard time (4 o'clock central standard time, 3 o'clock mountain time 2 o'clock Pacific time) each Tuesday presenting a dramatized program with incidental music under the general theme of Medical Emergencies and How They Are Met. The title of the program is Your Health. The program is recognizable by a musical salutation through which the voice of the announcer offers the toast: Ladies and gentlemen your health! The theme of the program is repeated each week in the opening announcement which informs the listener that the same medical knowledge and the same doctors that are mobilized for the meeting of grave medical emergencies are available in every community day and night for the promotion of the health of the people. Each program will include a brief talk dealing with the central theme of the individual broadcast.

Red Network—The stations on the Red network of the National Broadcasting Company are WEAf WEEI WTIC WIAF WTAF WCSH KYW WGBR WRC WGY, WBLA WCAE WTAM WWJ WMAQ KSD WHO WOW WDAF.

Pacific Network—The stations on the Pacific network are KGO KPO KFI KGW, KOMO KHQ KFSB KTAR.

¹ Kharasch, M. S., King, H., Stoll, A. and Thompson, M. J. The New Fargo Alkaloid Science 82: 206 (Feb.) 1936.

Network programs are broadcast locally or omitted at the discretion of the local station. The lists indicate stations to which programs are available.

The next three programs are as follows:

March 24 Hay Fever and Asthma Morris Fishbein M.D.
March 31 Let Your Doctor Decide W. W. Bauer M.D.
April 7 Middle Age R. G. Leland M.D.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ALABAMA

Personal—Dr William D. Burkhalter, Nashville, Tenn., was recently appointed health officer for the newly organized health department of Coosa County, with headquarters at Rockford.—Dr Robert E. Harper, Moulton, has been named health officer of Colbert County, succeeding Dr George W. Warwick, Birmingham.

ARKANSAS

Society News—The Mississippi County Medical Society was addressed, February 4, by Memphis physicians: Clement H. Marshall on pruritus, Matthew W. Seavright, menstruation; Shields Abernathy, cancer of the breast, and Dr Joseph E. Beasley, Blytheville, management of a ruptured appendix.—At a meeting of the Sebastian County Medical Society, February 11, Drs. Clarence B. Billingsley and Ralph E. Weddington, Fort Smith, discussed "Puerperal Sepsis: Prognosis and Treatment."—The Benton County Medical Society was addressed at Bentonville, February 13, by Drs. William A. Moore and Clyde L. McNeil, both of Rogers, on undulant fever and syphilis, respectively.—Dr Henry B. Hull, Mammoth Spring, discussed pneumonia before the Lawrence County Medical Society at Imboden, February 11.

CALIFORNIA

Personal—Dr Alexis Carrel of the Rockefeller Institute for Medical Research, New York, delivered the sixty-eighth charter day address on the Los Angeles campus of the University of California, March 20. Dr Carrel was recently appointed Hitchcock professor at the University of California in Berkeley for the spring semester.—Dr Robert A. Peers Colfax, president of the California Medical Association, was made an honorary member of the Stanislaus County Medical Society at a recent meeting in Modesto, in honor of his sixtieth birthday.—Dr Edwin S. Bennett, Olive View, has been appointed superintendent of Olive View Sanatorium, succeeding the late Dr. William H. Bucher.

San Francisco's Health—Heart disease, the leading cause of death in San Francisco, was responsible in 1935 for 2,491 deaths, giving the highest rate on record, 359 per hundred thousand of population. A rate of 172.87 per hundred thousand of population was noted for cancer. The general mortality rate for the city was 12.34 and the infant mortality rate 35 per thousand live births. The birth rate was 10.28 per thousand of population and the maternal death rate was 4.6 per thousand of all births. Pulmonary tuberculosis showed a rate of 58.58. The highest rate ever recorded for diabetes mellitus was made 29.72 per hundred thousand of population. There were 123 deaths from automobile accidents giving a rate of 17.74. Four deaths were reported for diphtheria as compared with one death in 1934. No cases of smallpox were reported. A death rate of 6.2 was recorded for influenza.

COLORADO

Society News—At a meeting of the Otero County Medical Society in La Junta, February 13, Drs. James B. Walton and Daniel R. Higbee, Denver, spoke on "Diseases of the New-Born and Kidney Infections," respectively.—Dr. Wilton A. Day, Delta, discussed vitamins before the Delta County Medical Society in Delta, February 28.—A symposium on cancer of the female genital tract was presented before the Pueblo County Medical Society, March 3, by Drs. Gerrit Heusinkveld, Kenneth D. A. Allen and George Zur Williams, all of Denver.—The Medical Society of the City and County of Denver was addressed, March 3, by Drs. Arthur J. Markley on Jonathan Hutchinson.—The General Specialist and Edward Jackson, Pioneers in Ophthalmology.

DISTRICT OF COLUMBIA

University News—Dr Esmond R Long, director of the Henry Phipps Institute, Philadelphia, gave the fifth lecture in the Smith-Reed-Russell series at the George Washington University School of Medicine, February 18, his subject was "Types of Pulmonary Tuberculosis in Relation to Spread of the Disease." Philip Bard, Ph D, Baltimore, gave the fourth lecture in the series, January 16, on "Neural Bases of Certain Forms of Emotional Expression."

Personal—John C Merriam, Ph D, president of the Carnegie Institution of Washington, was presented with the American Institute's gold medal, February 6 for his discoveries in paleontology, his effective promotion of research and his recognition of the place of science in human affairs.—Dr Frank Leech was honored at luncheon, January 14 in observance of his sixty-fifth birthday. A book of testimonials was presented to Dr Leech, signed by about eighty-two friends and associates present at the luncheon.

Society News—At a meeting of the Washington Society of Pathologists, January 4, papers were presented by Dr Laszlo Detre on Growth-Temperature and Antigenic Constitution of B Typhosus" and Joseph F Siler, Recent Investigation of Typhoid Vaccine at the Army Medical School.—Speakers before the Washington chapter of the Pan American Medical Association at its meeting January 26 included Drs John J Moorhead, New York, and William Wayne Babcock, Philadelphia, on "Trends in Traumatic Surgery" and "Diagnosis and Treatment of Diseases of the Colon" respectively.—Dr Mervin W Glover addressed the Louis Mackall Society recently on "Treatment of Epidemic Meningitis" and Dr Harry F Dowling, "Postoperative Pneumonia Cause, Prevention and Treatment."

Medical Bills in Congress—H R 11692, introduced (by request) by Representative Norton, New Jersey, proposes to establish a Commission on Mental Health to examine alleged insane persons and to make reports and recommendations to the court concerning the treatment, commitment and payment of the expense of support and maintenance of insane persons. The House Committee on the District of Columbia has voted to report the bill with recommendation that it pass. H R 11695, introduced by Representative Brewster, Maine and S 4195, introduced by Senator White, Maine propose to direct the Commission on Licensure to Practice the Healing Art in the District of Columbia to issue a license to practice the healing art to Dr Ralph Charles Stuart. H R 11717 introduced by Representative Lemke, North Dakota, proposes that no form of vaccination or inoculation shall hereafter be made a condition precedent in the District of Columbia for the admission to any public or private school or college of any person or for the exercise of any right, the performance of any duty, or the enjoyment of any privilege by any person.

ILLINOIS

Society News—Dr Ernest A Pribram, Chicago addressed the Will-Grundy County Medical Society, March 11 on "Blood Transfusion."—At a meeting of the Union County Medical Society, March 12, Dr Edward J Stieglitz, Chicago discussed "Nephritis—Functional Considerations in Treatment."—Dr Nathaniel G Alcock, Iowa City, addressed the Peoria City Medical Society, March 3, on "Malignancy of the Urinary Tract."

Chicago

Personal—Albert L Raymond, Ph D, of the Rockefeller Institute for Medical Research, New York, has been appointed director of the research laboratories of G D Searle and Company, Chicago, pharmaceutical manufacturers.—Samuel R Lewis, Chicago, heating and ventilating engineer, addressed the Research Club of the University of Illinois College of Medicine at its 250th anniversary meeting on "How Air May Be Heated and Cooled" March 11.

Society News—A symposium on cancer of the colon and rectum was presented before the Chicago Medical Society, March 11, by Drs Leon Bloch, Vernon C David and Charles B Puestow. A symposium on arterial diseases of the extremities constituted the program March 18, with Drs Samuel Perlow, Frank V Thiers and Geza de Takats as the speakers.—The Chicago Pathological Society was addressed among others March 9, by Noel Paul Hudson, Ph D, Columbus, Ohio and Enid A Cook, A B, of the department of bacteriology, University of Chicago, on "Relation of the Herpes Antiviral Power of the Blood to Sex, Pregnancy and Menstruation."—At a meeting of the Chicago Roentgen Society, March 12, speakers included Drs Dallas B Pemister on "Calcium Carbonate in Cholelithiasis."—The Chicago Tuberculosis Society was addressed, March 13, by Drs Frederick Lieberthal on

"Urinary Tuberculosis—Its Relation to the Tuberculosis Problem in General", Thomas O Nuzum, Janesville, Wis, "Intrathoracic Fluid," and Jay Arthur Myers, Minneapolis, "Tuberculosis Lesions in Medical Students and Nurses."—Among others, Dr Henry W Meyerding, Rochester, Minn, discussed "Dupuytren's Contracture" before the Chicago Orthopaedic Society, March 13. Dr Roger Anderson, Seattle, discussed a paper presented by Dr James J Callahan on "Fractures of the Patella."

INDIANA

Personal—Dr Joseph S Skobba resident physician at the Fort Wayne State School since 1932, has been transferred to the Central State Hospital at Indianapolis, he has been succeeded at the Fort Wayne institution by Dr Arsenius R Episcopo, East Chicago.

Society News—Dr Aloysius James Larkin, Chicago, discussed common uses of radium before the St Joseph County Medical Society in South Bend March 4.—At a meeting of the Jasper-Newton County Medical Society in Rensselaer, February 27, Dr Alexander A Goldsmith, Chicago, spoke on gastro intestinal infection.—The Daviess-Martin Counties Medical Society heard Dr Leonard A Ensminger, Indianapolis, discuss fractures at its meeting in Washington, February 25.

Graduate Courses—The fifth annual graduate meeting of the Indiana State Medical Association will be held at the Claypool Hotel and the Indiana University School of Medicine, Indianapolis, April 8-9. Both days will be given over to discussions of cardiovascular, renal and neoplastic diseases. The meeting will be held during the annual graduate course of Indiana University School of Medicine, April 6-11. The latter course will be devoted to clinics in the forenoon and didactic work in the afternoon.

IOWA

Examination in Basic Sciences—The Iowa Board of Examiners in the Basic Sciences will conduct a written examination at the state capitol, Des Moines, April 14, at 9 a m. Those wishing to take the examination must obtain an application blank from the secretary, fill it out and return it, together with the fee of \$10, so as to reach the secretary, Edward A Benbrook, V M D, Iowa State College, Ames, not later than Monday March 30.

KANSAS

Wichita Graduate Clinic Day—The Sedgwick County Medical Society will hold its first annual graduate clinic in Wichita, April 7. The program will be an all day clinical meeting at the Alis Hotel, consisting of demonstrations of clinical and pathologic material presented by members of the society.

The Porter Lectures—Dr Jennings C Litzenberg, professor of obstetrics and gynecology, University of Minnesota Medical School, Minneapolis, presented the sixth course of lectures under the Porter Lectureship in Medicine of the University of Kansas School of Medicine, March 17-18. The titles of the lectures were "The Pathology of Ectopic Pregnancy," "The Physician Who Became a God," and "Missed Abortion."

Society News—A symposium on fractures was presented before the Sedgwick County Medical Society, February 18, by Drs Earl J Frost, Charles R Rombold, Hervey R Hodson, Arthur E Bence, Earl L Mills, Edwin D Ebright and Alonzo P Gearhart, all of Wichita. The society was addressed, March 17, by Drs Vincent L Scott on "Rheumatic Infections in Childhood" and Jacob F Gsell "Foreign Bodies of the Eye, Ear, Nose and Throat." Speakers at the March 3 meeting were Drs John L Klemmhekel and John G Missildine on "Diabetes in Pregnancy" and "Diagnosis in Kidney Infection" respectively.—Dr Warren H Cole, St Louis, addressed the Wyandotte County Medical Society, March 3, on "Causes of Failure in Gallbladder Surgery."

MARYLAND

The Thayer Lectures—Philip E Smith, Ph D, professor of anatomy, Columbia University College of Physicians and Surgeons, New York, gave the William Sydney Thayer and Susan Read Thayer Lectures in Clinical Medicine, March 12 13, at Johns Hopkins Hospital, Baltimore. His lectures were entitled "The Influence of the Hypophysis on the Uterus and Menstruation" and "Relation of the Hypophysis and Ovaries to the Menopause."

University News—Charles G King, Ph D, professor of chemistry, University of Pittsburgh, gave one of the De Lamar lectures in hygiene at Johns Hopkins University School of Hygiene and Public Health, March 10. His subject was "The

Prescorbutic State' The Society of Hygiene of the University was addressed, February 26 by Justin M. Andrews, ScD and Harry F. White on 'A Survey of Protozoa Parasitic in Wild Rats in Baltimore, with Special Reference to *Endamoeba histolytica*,' and Roscoe R. Hyde, Ph.D. Baltimore, 'Immunity to the Virus of Infectious Myomatosis.'

MASSACHUSETTS

Dr. Zinsser Named Charles Wilder Professor—Dr. Hans Zinsser, professor of bacteriology and immunology, Harvard Medical School, Boston, has been appointed Charles Wilder professor of bacteriology and immunology at the school. This is not a new professorship but it has only recently been assigned to the department of bacteriology.

Physicians' Art Exhibit—The Physicians' Art Society will hold its annual exhibition in the galleries of Doll and Richards, Boston, April 27-May 9. In addition to paintings, drawings and sculpture, other creative specimens of handicraft are eligible. Photographs will not be accepted. There is no limit to the number of subjects which can be sent by any one person, but a professional jury will select a limited number and supervise their hanging. Nothing will be accepted that has been shown at any of the previous exhibitions. All inquiries should be addressed to Mr. James F. Ballard, secretary of the society, at the Boston Medical Library.

Course in Bacteriology—A summer course in general and sanitary bacteriology will be offered by the department of biology and public health, Massachusetts Institute of Technology, Cambridge, June 16-July 28. The course will consist of lectures, recitations, demonstrations, laboratory work and appropriate field trips. The course is designed for beginners in bacteriology and to appeal to public health nurses, health education workers, public health laboratory and hospital technicians, sanitary inspectors, water works operators, milk inspectors, milk analysts and students preparing for careers in biologic science, public health or medicine. All inquiries should be addressed to Prof. Murray P. Horwood, Ph.D., Massachusetts Institute of Technology.

MICHIGAN

Psychiatric Parole Clinic—The opening of the psychiatric parole clinic recently established at Eloise Hospital, Eloise, will take place April 1, newspapers report. The clinic will sponsor the classification and examination of patients in county institutions and return the mildly affected to their homes. Constant supervision of these patients will be maintained through a follow-up system (THE JOURNAL, Dec. 14, 1935, p. 1933). A Detroit branch of the clinic will also be opened about April 1 in the juvenile court building, it was stated. Dr. Martin H. Hoffmann is in charge of the work.

Fellowships in Public Health Administration—Dr. Morley B. Beckett, Lansing, formerly director of county health administration, state health department, has been appointed to the staff of the W. K. Kellogg Foundation to work out details for a fellowship system to enable graduate students in public health administration and kindred fields to obtain practical experience. It is reported. Two full-time one-year fellowships are now being planned, for which applicants must be graduates of recognized schools with special training in the public health field. Dr. Beckett has served with the health department of Cleveland, as assistant health commissioner of Saginaw and health officer of Isabella County. He plans to devote six months to the development of these fellowships.

Annual Concert of Medical Society's Orchestra—The symphony orchestra of the Wayne County Medical Society will give a joint concert with the glee club of the society at the Detroit Institute of Arts, March 30. The program is made up of eight selections by the orchestra and the glee club and two cello solos by Georges Miquelle, director of the orchestra. The Wayne County Medical Society Symphony Orchestra was established in January, 1935. In April it made its first appearance with twenty-eight members. Fifty musicians, some of whom are dentists, now make up the personnel. Officers are Drs. Frank M. MacKenzie, president; William P. Woodworth, vice president; Jacob Agins, secretary; Arthur E. Hammond, treasurer; and Raphael Altman, assistant conductor.

MISSISSIPPI

Bills Introduced—S. 442 proposes to create a county medical association in each county and to deny to a physician not a member of such a county medical association the right to practice medicine in the state. The county medical association for each county would be in complete charge of all public health work in the county or area of its organization and of all such public health work heretofore delegated to the state board of

health. The state board of health would continue as a centralized directing agency for the distribution of educational matter concerning public health and would promulgate rules and regulations for the prevention and spread of contagious infectious or epidemic diseases. It would be the duty of the several county medical associations to enforce those rules and regulations within their respective areas. H. 603 proposes to create a board of cosmetic therapy and to regulate the practice of cosmetic therapy or beauty culture. Such licensees are to be permitted among other things to remove superfluous hair about the body of any person. H. 607 proposes that all communications made to a physician or surgeon by a patient under his charge or by one seeking professional advice are hereby declared to be privileged and such physician or surgeon shall not be required to disclose the same in any legal proceeding except at the instance of the patient or in any case where the physical condition of the patient is voluntarily put in issue by the patient.

MISSOURI

Publicity and the Press—Until such time as a policy and adequate working rules can be adopted the president of the St. Louis Medical Society, under authority from the council, will handle any publicity or material for the press according to the society's weekly bulletin. This decision was made recently when questions arose that required action by a committee on publicity. The further need for such a committee was emphasized by a policy recently adopted by Washington University School of Medicine under which all news items emanating from the school and its affiliated hospitals are to be referred to a committee of the St. Louis Medical Society before publication in the lay press, the bulletin said.

St. Louis Clinics—The annual spring conference of the St. Louis Clinics will be held for one week beginning April 27. Clinical demonstrations will be given daily, and Tuesday evening the regular meeting of the St. Louis Medical Society will be under the direction of the clinics. Demonstrations by members of the medical reserve of the seventh corps area will be given from 4 to 5 p. m. each day and on Monday and Wednesday evenings. St. Louis physicians will present the entire program, which will be strictly clinical, providing a general review and a discussion of newer methods employed in the diagnosis and treatment of all branches of medicine. Further information may be obtained from the secretary, St. Louis Clinics, 3839 Lindell Boulevard, St. Louis.

NEBRASKA

Society News—The Omaha-Douglas County Medical Society, Omaha, had the following guest speakers, March 11: Drs. Frank E. Adair, New York, on 'Carcinoma of the Breast'; Erum R. Schmidt, Madison, Wis., 'Therapeutic Use of Oxygen'; Robert H. Kennedy, New York, 'Colles Fracture'; and Alfred W. Adson, Rochester, Minn., 'Trigeminal Neuralgia: Differential Diagnosis and Surgical Treatment'.—Drs. Rex L. Murphy and Paul J. Connor, Denver, addressed the Scotts Bluff County Medical Society, February 13, on 'Otitis Media, Mastoiditis and Sinus Diseases' and 'Hypothyroidism' respectively.

NEW YORK

Milk-Borne Epidemic of Scarlet Fever—An outbreak of about 200 cases of scarlet fever in Wellsville, a town of 6,000, in January was traced to raw milk or cream, *Health News* reports. Of 115 cases investigated, 103 were in households regularly supplied with raw milk or cream supplied by one dealer. On one of the farms was found a cow with mastitis. It was also found that two sons of the owner of this farm had had sore throats about the time the cow showed infection. From this cow a hemolytic streptococcus having the characteristics of the type usually associated with human infections was isolated. Five deaths had occurred up to the time of the report.

Bills Introduced—A. 1719 proposes (1) to authorize the state department of health to promulgate requirements, specifications and tolerances for clinical thermometers and to designate by appropriate markings or seals such clinical thermometers as comply with its regulations and (2) to limit the sale of clinical thermometers in the state to thermometers approved by the department. A. 1720 proposes to make it unlawful to sell or to possess for the purpose of selling any clinical thermometer not conforming to certain requirements set out in the bill. A. 1731 proposes to require the board of regents of the University of the State of New York prior to Jan. 1, 1937, to establish and appoint a state board of chiropractic examiners. This chiropractic board would establish rules and regulations

fixing the qualifications of applicants for licenses to practice chiropractic, the examination of such applicants, and the granting and issuing of licenses to practice chiropractic. The bill proposes to define chiropractic, in effect, as the adjustment of the human skeletal frame, according to the doctrine of chiropractic. Such practice is not to include the science of surgical operations, the use of instruments, or the prescribing or use of drugs or medicines, but x-rays may be used for the purpose of examination. S 1431, to amend the pharmacy law, proposes that no manufacturer or wholesaler may sell any poisonous, deleterious or habit forming proprietary medicine except to the proprietor of a pharmacy, drug store or registered store or to persons authorized to make purchases for state institutions or public or private hospitals. S 1443 proposes to regulate the conduct of clinical laboratories and to require such laboratories to be under the immediate supervision of a licensed clinical laboratory technologist or a person holding a valid and unrevoked license to practice medicine and surgery in the state. The bill proposes to define a clinical laboratory as "any place, establishment or institution or department whether or not it is termed or called a clinical laboratory or given any other designation of like import, organized for the practical application of one or more of the fundamental sciences, such as bacteriology, biochemistry, serology and parasitology and other allied subjects, by the use of specialized apparatus equipment or methods for the purpose of furnishing regularly licensed practitioners of the healing arts or other person with the results of such laboratory examinations or tests or analysis of specimens submitted." S 1522 and A 1884, to amend the laws relating to the conduct of maternity hospitals, propose to require such hospitals in the city of New York to be licensed by the commissioner of hospitals of New York City. S 1534 and A 1793 propose to create a board of psychiatric examiners and to prescribe qualifications for qualified psychiatrists. S 1559 to amend the workmen's compensation act, proposes to permit the annual expenditure from the vocational rehabilitation fund for five years of a sum not exceeding \$50,000 to make studies and disseminate information on the subject of control and prevention of diseases caused by inhaling harmful dusts. A 1797 to amend the workmen's compensation act proposes to authorize compensation for total disability or death from silicosis or other dust diseases. It proposes that compensation shall not be payable for partial disability. The bill proposes to limit the medical treatment for an employee disabled by an occupational disease due to or resulting from the inhalation of harmful dust to a period of ninety days from the date of disablement and, on the order of the industrial board, for an additional ninety days.

New York City

Anniversary of Hospital Service—The New York City Department of Hospitals announces that a public meeting will be held at the New York Academy of Medicine, May 12, to celebrate the completion of 200 years of continuous hospital service by the city. Dr Sigmund S Goldwater, commissioner of hospitals, will preside and speakers will be Mayor Fiorello H La Guardia, on the functions of the municipality in the care of the sick, Dr Henry E Sigerist, Baltimore, historical development of medicine in the United States, and George E Vincent, Ph D, former president of the Rockefeller Foundation, responsibilities, opportunities and social significance of the hospital.

Society News—Drs Francis R Packard, Philadelphia and Edgar Erskine Hume, librarian, Army Medical Library, Washington, D C, addressed a stated meeting of the New York Academy of Medicine, March 5, arranged in cooperation with the section of historical and cultural medicine. Dr Packard spoke on "William Cheselden Some of His Contemporaries and Their American Pupils Before the Hunters" and Dr Hume on "The Medical Work of the Knights of St John of Jerusalem."—Drs Cornelius G Dyke and John E Scarff, among others, addressed the New York Neurological Society at a joint meeting with the section of neurology of the New York Academy of Medicine, March 3, on "A Pathognomonic Encephalographic Sign of Chronic Subdural Hematoma" and "Treatment of Obstructive Hydrocephalus by Third Ventriculostomy" respectively.—The Philadelphia Metabolic Association presented the program of the clinical section of the New York Diabetes Association, March 20, on "Diabetic Acidosis." Speakers, all of Philadelphia, were Walter G Karr, chemistry, Drs Joseph T Beardwood Jr clinical aspects, Edward S Dillon, complications, and Edward L Bortz treatment.—A symposium on "special surgery" was presented before the International and Spanish Speaking Association of Physicians, Dentists and Pharmacists, February 21, by Drs Joseph East-

man Sheehan, Lewis Gregory Cole, Pol N Coryllos and William H Cary.—The Bronx County Medical Society recently adopted a resolution favoring adoption of the child labor amendment to the Constitution of the United States.

NORTH CAROLINA

Personal—Dr Samuel B McPheeters, Charlotte, has been appointed health officer of Wayne County to take office April 15, after he has completed a course at the University of North Carolina.—Dr John F Foster, Sanford, was recently honored by being chosen "man of the year" in Lee County, he received a silver loving cup.—Dr Mott P Blair, Marshville, was honored at a community meeting, February 28, in recognition of his long service. He was chosen by the Marshville Federated Clubs as the outstanding citizen of the town.—Dr Lorenzo L Parks, Auburn, Ala, has been appointed health officer of Edgecombe County.

Society News—Dr John T Saunders, Asheville addressed the Buncombe County Medical Society, Asheville, February 3 on "Injuries to the Knee Joint"—Dr Lawrence T Royster, University, Va, was the guest speaker at the annual meeting of the Raleigh Academy of Medicine, February 1, on "Nephritis in Childhood"—Dr Francis Bayard Carter, Durham addressed the Guilford County Medical Society, Greensboro January 2, on "Interruption of Pregnancy"—Drs Malory A Pittman, Wilson, and Hugh A Thompson, Raleigh, addressed the Fourth District Medical Society at a meeting in Wilson February 11, on "Pelvicephalometry" and "Traumatic Surgery" respectively.—Drs William Eugene Ketter, Kinston and Herbert A Codrington, Wilmington, addressed the New Hanover County Medical Society, Wilmington, January 16, on "Sodium Lactate Therapy in Severe Acidosis" and "Medical and Surgical Treatment of Gallbladder Diseases" respectively.

OKLAHOMA

Personal—Dr Maurice L Peter, Blackwell, has been appointed health officer of Kay County to succeed Dr Luther H Becker, Blackwell.—Dr Marshall D Carnell, Okmulgee, has been appointed health officer of Okmulgee County to succeed the late Dr John J C Rembert.

Society News—Speakers at a meeting of the Tulsa County Medical Society March 9, were Drs Gregory A Wall and Herbert S Nauheim, on "The Fundamental Factor in the Cure of Hernia" and Blood Groups and Paternity," respectively, and Floyd L Rheam, attorney, "Some Legal Problems in Medicine." The Tulsa society was addressed, February 17, by Drs Homer A Ruprecht and Davy L Garrett, Tulsa on "Recent Advances in the Study of Biliary Diseases", the program February 24 was a paper by Dr Felix M Adams Vinita, on "The Management of Mental Cases"—Dr Robert M Shepard, Tulsa, addressed the Craig County Medical Society, recently, on pulmonary tuberculosis.

OREGON

Society News—Dr Paul A Pemberton, Woodburn addressed the Polk-Yamhill-Marion Counties Medical Society, Salem, January 14, on artificial fever therapy.—A discussion of pneumonia was presented before the Multnomah County Medical Society, Portland, February 19 by Drs James Marr Bisillon, Thomas D Robertson and Sherman E Rees.—Dr John C Lyman, Walla Walla, Wash addressed the Umatilla County Medical Society, Pendleton March 10, on "Renal Tuberculosis", Dr Carl J Johannesson Walla Walla, presented unusual x-ray films and discussed technical errors in films resulting in wrong interpretations.

PENNSYLVANIA

Testimonial Dinner—Drs David S Funk, John B McAlister and John F Culp, Harrisburg, were guests of honor at a dinner given by central Pennsylvania alumni of the University of Pennsylvania at the Harrisburger Hotel February 20. More than sixty attended. Dr McAlister, who is a former president of the Medical Society of the State of Pennsylvania graduated in 1887, Dr Culp graduated in 1886 and Dr Funk in 1881.

Society News—Drs George J Kastlin and John M Johnston, Pittsburgh, addressed the Beaver County Medical Society March 12, on "Blood Dyscrasias as Seen in General Practice" and "Chemotherapy in Pneumonia" respectively.—Dr Frank N Allan Boston, addressed the Lycoming County Medical Society Williamsport, March 13, on General Management of the Diabetic.—Dr Marc W Bodine Williamsport, addressed the Tioga County Medical Society February 21 on cancer of the stomach.

Philadelphia

Newbold Lectures—The thirty-sixth group of Mary Scott Newbold Lectures was delivered March 4 before the College of Physicians of Philadelphia. The lecturers were Drs Franklin L. Payne, on "Practical Aspects of Modern Female Endocrinology" and Leonard G. Rowntree, 'Organotherapy from the Internist's Viewpoint'.

Society News—Speakers before the College of Physicians of Philadelphia, February 5, were Drs Louis H. Clerf and Baxter L. Crawford, on "Benign Glandular Tumors of the Bronchus", Dorothea E. Smith, Ph.D., Edward J. Czarnetzky, Ph.D., and Dr. Stuart Mudd, 'Evaluation of Mercurial Antiseptics in the Presence of Serum' and Dr. Walter Hughson, 'Experimental Investigations of the Physiology of the Ear'.—Dr. Edward A. Strecker addressed the Obstetrical Society of Philadelphia, February 6, on 'The Mental State of the Woman During Pregnancy and the Puerperium'.—Dr. Ursus V. Portmann, Cleveland, addressed the Philadelphia Roentgen Ray Society, February 6, on 'Postoperative Prophylactic Roentgen Therapy in Treatment of Carcinoma of the Breast'.—The New York Surgical Society held a joint meeting with the Philadelphia Academy of Surgery, February 12 with the following speakers, among others: Drs. Edward T. Crossan, on "Bone Drainage in Acute Hematogenous Osteomyelitis", Lewis K. Ferguson, 'Painful Shoulder', Alexander Randall and Frederick A. Bothe, 'Value of Preoperative Irradiation in Tumor Tests'.—A discussion of meningitis featured the meeting of the Philadelphia Neurological Society, February 28, with the following speakers: Drs. Charles Armstrong Washington, D. C., James W. Watts, Ignatius S. Hneleski and Ernest L. Noone.

RHODE ISLAND

Bill Enacted—H 510 amending the workmen's compensation act, has become a law. Among other things, the new law requires the employer to furnish to an injured worker reasonable medical and hospital services and medicines without limit as to amount during the first eight weeks after an industrial injury, and for such other period as in the opinion of the director of labor may be deemed necessary. The prior law limited the employer's liability for medical services to \$100 or \$150, according to circumstances.

Bills Introduced—H 735 proposes, among other things, that "a licensed physician or surgeon cannot, without the consent of his patient, be examined in a civil action, as to any information acquired in attending the patient, which was necessary to enable him to prescribe or act for the patient." H 745 proposes to require all applicants for licenses to practice any form of the healing art, as a condition precedent to examination by their respective "professional" boards, to pass examinations in anatomy, physiology, pathology, diagnosis, chemistry, bacteriology and public health, to be given by a state board of examiners in the basic sciences, which the bill proposes to create. This basic science board is to consist of three members appointed by the director of public health because of their proficiency in the basic sciences. Neither the director of public health nor any member of any of the various 'professional' examining boards is to be a member of the basic science board. H 747, to amend the uniform narcotic drug act, proposes to define narcotic drugs so as to include cannabis and every substance neither chemically nor physically distinguishable from it. H 748 proposes that in an appeal from an order of a licensing board revoking a license to practice medicine and surgery, osteopathy or chiropractic the order of the board shall remain in effect during the pendency of the appeal. H 749 proposes to authorize the state department of public health to make examinations of persons reasonably suspected of having venereal disease and to quarantine or to isolate persons infected with any venereal disease whenever quarantine or isolation is necessary to protect the public health.

SOUTH CAROLINA

Bill Passed—H 1640 has passed the house, authorizing the city council of any municipal corporation of more than 5,000 inhabitants and less than 10,000 inhabitants which has acquired constructed or caused to be constructed a hospital, to establish a city hospital commission to operate and manage such hospital.

TENNESSEE

Personal—Dr. Alonzo C. Hardison Jr. of Marysville has been appointed director of the Blount County health department to succeed Dr. Owen F. Agee of Marysville who resigned in November.—Dr. John B. Youmans, associate professor of medicine, Vanderbilt University School of Medicine, Nashville, has been appointed director of graduate instruction. Dr. You-

mans will have special charge of courses given for practicing physicians with the cooperation of the Commonwealth Fund.

Society News—Dr. Carl S. McMurray addressed the Nashville Academy of Medicine, February 4, on "Comparison of Hysterectomy and Radiation Therapy in Fibroid Tumors of the Uterus".—Dr. John T. Murphy, Toledo, Ohio, addressed the Chattanooga and Hamilton County Medical Society, Chattanooga, February 13, on bone tumors.—Dr. Morris Fishbein, Chicago, editor of THE JOURNAL, addressed the Madison County Medical Society, Jackson, February 26. At a meeting February 4 Dr. James B. Miller Jackson, presented a paper on "Minor Surgery in Treating Infections of the Hand".—Drs. Olin West, Chicago, Secretary, American Medical Association, and Harrison H. Shoulders, Nashville secretary, Tennessee State Medical Association, addressed the Memphis and Shelby County Medical Society, March 17, on medical economics. Drs. Jerome L. Morgan and Frank T. Mitchell, Memphis, addressed the society, February 18, on "Prostatism" and "Anhydremia Associated with Intoxication" respectively.

TEXAS

Society News—Drs. Robert L. Moore and John E. Dunlap, Dallas, addressed the Kaufman County Medical Society, Terrell, February 4, on "Tuberculosis in Infancy and Childhood" and "Allergy" respectively.—Speakers at a meeting of the Lamar County Medical Society in January at Paris were Dr. Davis Spangler and A. L. Frew, D.D.S., Dallas, on 'Preoperative Care of the Cleft Palate Patient' and 'Treatment of Cleft Palate' respectively.—Dr. Edward Delehanty, Denver, was guest speaker at a meeting of the Palo Pinto Medical Society, Mineral Wells, February 3 on 'The Development of Neurology'.—Drs. Charles P. Hawkins and George R. Enloe, Fort Worth, addressed the Tarrant County Medical Society, Fort Worth, February 4, on "External Cephalic Version" and "Epispadias in the Female" respectively.—Dr. Jackson Stewart Cooper, Abilene, addressed the Taylor-Jones Counties Medical Society, Abilene, February 11, on "Rupture of the Urinary Bladder and Urethra".

VIRGINIA

McGuire Lectures—The annual Stuart McGuire Lectures of the Medical College of Virginia, Richmond, will be delivered by Dr. Edward C. Rosenow, Rochester, Minn., April 6-7, at the Richmond Academy of Medicine. Dr. Rosenow's subjects will be 'Focal Infection and Elective Localization' and 'Streptococci in Relation to Diseases of the Nervous System'. During the day of April 7 clinics will be conducted by the faculty of the college.

Personal—Dr. Fred J. Wampler, Richmond, has been appointed medical adviser to the Works Progress Administration of Virginia.—Dr. W. Johnson Strother, Culpeper, was guest of honor at a banquet recently given by the Medical-Dental Society of Culpeper County, paying tribute to his long service as a physician. Speakers included H. B. Lacy, D.D.S., Culpeper; Rev. Thomas W. Hooper and Drs. Charles Bruce Morton II and John H. Neff, University; James G. Brown, Woodville; Jesse N. Clore, Madison; and Martin B. Hiden, Warrenton.

Society News—The South de Virginia Medical Association held its quarterly session at the Central State Hospital, Petersburg, March 10. Speakers were Drs. Thomas J. Wheelton, Richmond, on "Value of the Cystine Content Determination in Treatment of Arthritis", Guy W. Horsley, Richmond, "Postoperative Treatment of Abdominal Cases", Charles R. Robins, Richmond, 'Original Bassini Operation', Page E. Thornhill, Norfolk, "Two Important Prenatal Examinations and Obstetric Technique in a Poor Home", Wright Clarkson and Wilbur Allen Barker, 'Radiosensitivity and Radioreistance in Tumor Therapy'.—The Postgraduate Medical Society at a meeting February 11 changed its name to the Fourth District Medical Society. Speakers were Drs. Thomas G. Hardy, Farmville, on differential diagnosis of acute conditions in the abdomen; John A. Proffitt, Burkeville, acute conditions in the chest; and John A. B. Lowry, Crewe, prevention and treatment of puerperal sepsis.

WYOMING

Scarlet Fever Prevalent—The Wyoming state board of health reported 331 cases of scarlet fever in December, with five deaths; 325 cases in January, with no deaths; and 361 cases with no deaths in the first twenty days of February. An account in *Colorado Medicine* points out that the disease is mild and that about a third of the cases have occurred in persons more than 21 years old. The U. S. Public Health Service reported January 25 that scarlet fever was unusually prevalent through the West North Central, Mountain and Pacific states.

GENERAL

Tri-State Hospital Meeting—The Tri-State Hospital Assembly will be held in Chicago, May 6-8, at the Hotel Sherman. The assembly comprises the hospital associations of Indiana, Illinois and Wisconsin, together with associated groups.

Seminar on Health Education—The National Tuberculosis Association will sponsor a seminar on health education in New Orleans, April 21, the day before the opening of its annual session. There will be two courses one on health education and one on popular health education. Emphasis will be placed on practical ways and means of teaching the child and reaching the adult public.

Medical Bill in Congress—*Change in Status* H R 11035, making appropriations for the War Department for the fiscal year ending June 30 1937 has been reported to the Senate, with amendments. The provision in the bill, as passed by the House forbidding the maintenance of medical units in the Reserve Officers' Training Corps was stricken from the bill by the Senate Committee on Appropriations. An additional appropriation was proposed to provide for the establishing and maintaining of such units.

Public Safety Program—The National Safety Council will soon launch a public safety program to be carried out in conjunction with the five year campaign now in force to reduce traffic accidents. Recent expansion of the council's field for traffic accident prevention, made possible by a grant from the automotive industry, will facilitate the safety program. Eight field men will be available in various parts of the United States to assist state and community officials and organizations in their efforts to reduce accidents. Pamphlets written in popular style will be prepared for nationwide distribution, and illustrated articles will be prepared and distributed to newspapers. The new program is a response to various cities and states that have requested assistance in organizing definite public safety plans.

Changes in Status of Licensure—The Rhode Island Department of Public Health reports the following disposition of a license revocation.

Dr. William H. H. Briggs, Pawtucket license revoked by action of the state supreme court which recently upheld revocation of his license by the department in 1933 on a charge of abortion.

The New York State Board of Medical Examiners recently reported the following action.

License of Dr. Vladimir Gregory Burtan, whose last known address was 133 East Fifty Eighth Street, New York, revoked at a meeting Dec 20 1935 because of his conviction of a felony.

At a meeting of the Board of Health of Hawaii, Dec 28, 1935, the following action was taken.

Dr. Mars L. Madsen, formerly of Paia, Hawaii, license revoked for habitual interference.

The Massachusetts Department of Registration in Medicine has reported the following.

Dr. Russell B. Street, Conway, license revoked following his admission to the Northampton State Hospital.

Society News—Dr. Donald B. Armstrong, New York, was elected president of the National Health Council at its annual meeting February 6 in New York. He succeeds Theodore Roosevelt.—The American Institute of Nutrition will hold its third annual meeting in Washington, D. C., March 25. John R. Murlin, Ph.D., Rochester, N. Y., is president of the institute and Icie G. Macy, Ph.D., Detroit, secretary.—The American Association of the History of Medicine will hold its annual meeting at Atlantic City, May 4, with afternoon and dinner sessions at Haddon Hall.—The annual convention of the Catholic Hospital Association will be held at the Fifth Regiment Armory, Baltimore, June 15-19.—The American Society for the Hard of Hearing will hold its annual meeting in Boston, May 26-30, at the Hotel Statler.—Dr. William F. Braasch, Rochester, Minn., was chosen president of the Northwest Regional Conference at its session in Chicago, February 16. The meeting next year will again be held in Chicago.—National Hospital Day will be observed May 12, the birthday of Florence Nightingale. Since 1921 hospitals have held open house on this day to acquaint the public with their work.—The southern section of the American Congress of Physical Therapy will hold a meeting in New Orleans March 23-24. Guest speakers will include Chicago physicians Drs. Abraham R. Hollender on "Newer Aspects of Ionization Therapy in Nasal Allergic Disorders," Oscar B. Nugent, "Evaluation of Phototherapy in Ophthalmology," Harry C. Rolnick, "Transurethral Electroresection in Prostatic and Bladder Neck Obstructions," and John S. Coulter, "Physical Therapy in Relation to Arthritis," and Howard A. Carter, B.S., secretary, Council on Physical Therapy, American Medical Association, Chicago, "Generation of High Frequency Currents, Discussion of Concepts, Units and Radio Circuits as Applied to Short Wave Diathermy."

Reform of the Coroner's Inquest

The ancient office of coroner can be traced back to the twelfth century. His function is to inquire into deaths not due to natural causes, and on the whole he has done this efficiently through the centuries. But this archaic office has fallen behind the standard required in modern times and has been the subject of much criticism. The inquiry is not carried on by the strict rules of evidence which prevail in other courts, so that prejudice may be unfairly aroused and a case built up against an accused person. Moreover, before a case can come before a judge the accused has to appear in police court and the proceedings that have taken place before the coroner are unnecessarily duplicated. Radical reform has been delayed so long because the English are a conservative people, attached to ancient institutions which they alter only after much criticism. But they are also practical and, as their history shows, have no difficulty when aroused in doing what is necessary. A committee of well known lawyers containing one representative of the medical profession, Sir Farquhar Buzzard, regius professor of medicine in the University of Oxford, was appointed by the government a year ago to inquire into the law and practice of coroners' inquests. The committee has now made recommendations that will radically reform the coroners' inquest and remove defects that have existed too long. The recommendations are as follows.

The coroners' jurisdiction should be limited to the investigation of the facts how, when and where the death occurred and this investigation should be clearly distinguished from any trial of liability, whether civil or criminal. In cases of suicide the press should be prohibited from publishing an account of the proceedings, though the inquest should be held in public as at present. All that the press should be allowed to publish is the fact that the inquest has been held, the name and address of the deceased and the verdict that he died by his own hand. The verdict of *felo de se* should be abolished, and the verdict in cases of suicide should simply be that the deceased died by his own hand. No inquiry into his state of mind should be made save as it might throw light on the question whether he took his own life and no reference should be made in the verdict to the state of his mind. There are several reasons for this change. Out of consideration for the deceased's relatives rather than because of justification by the facts, juries have often brought in a verdict of 'suicide while temporarily insane'. The inquiry into the state of mind of the deceased has led to the reading in court of letters and other intimate documents written by him which have often been painful and harmful to the living. The coroner should no longer have the power to commit any person for trial on a charge of murder or manslaughter, and the inquisition should not name any one as guilty of these offenses. If questions of criminality are involved the laws of evidence should be observed. When a person is suspected of causing death he should not be called and put on oath unless he so desires and should not be cross examined. Coroners' courts should be prohibited from dealing with questions of civil liability. Verdicts of censure or exoneration should be prohibited but this does not exclude general recommendations designed to prevent further fatalities. The coroner should have a discretion to dispense with holding an inquest in the case of deaths due to simple accidents or chronic alcoholism or deaths under an anesthetic or during an operation. But he should be obliged to hold an inquest in cases of suspected industrial disease. Necropsies ordered by coroners, save in exceptional cases, should

be made by pathologists whose names appear on a government list, to be compiled under the advice of an expert committee. For cases of industrial disease there should be a special list of pathologists. At present the majority of necropsies performed on the order of the coroner are done by general practitioners, usually by the physician who attended the deceased, and it is a matter of the coroner's discretion whether a pathologist is employed or not. The clinical and postmortem evidence should be collated, and for this purpose the coroner or pathologist should be empowered to ask the practitioner who attended the deceased to supply a report or to be present at the necropsy, for an appropriate fee. In criminal cases a chief officer of police should be empowered to request the coroner at any time before the inquest is over to order a necropsy. The routine work necessary before and after a necropsy should be performed by the pathologist's assistant and not by police officers.

Qualifications for appointment as coroner should be primarily legal. Candidates should satisfy tests not only of their knowledge of law and their practical experience but also of their acquaintance with medical jurisprudence. Only lawyers should be appointed, as the sifting of evidence requires legal training. A coroner without medical knowledge would be fully informed of the medical aspects of the case by the medical witnesses. At present the majority of coroners are lawyers but a minority are physicians. The committee recognizes that the latter have done valuable work but considers that legal training is of greater importance than medical. The *British Medical Journal* objects to this recommendation. It admits the desirability of the coroner having a legal qualification but thinks that it is almost essential that he should have a medical one. It points out that there are a large number of persons qualified for both professions which would be increased if the double qualification should be recognized as highly desirable in a coroner.

New Method of Producing Citric Acid

The Italian embargo on the export of lemons resulting from the need for them in the Abyssinian war, would have resulted in world shortage of citric acid but for a British discovery. Until 1929 citric acid was obtained only from lemons and the whole supply was in the hands of Italian manufacturers. When the export became restricted experiments were made in England and it was found that the black mold which forms on fruit turns sugar into citric acid. By a process of fermentation the black mold can be grown direct on sugar. From this was evolved a simple method of producing the acid which is just as good as the original and is cheaper.

Antimosquito Measures for a Tropical Air Line

The new air line which is to be opened between the Sudan and Nigeria is awaiting a certificate of freedom from disease-carrying mosquitoes. It will not be operated until the necessary steps have been taken to clear the air-dromes and the land in their vicinity of mosquitoes which might carry the germs of yellow fever. Fortunately the flying range of the mosquitoes does not exceed 7 miles and the areas to be treated are therefore not extensive. This measure is being taken as a precaution against interruption of the service in the future and also that the line may comply strictly with the provisions of the International Sanitary Convention. The new line passes from Khartoum across the Sudan into French Equatorial Africa on its way to Kano in Nigeria where it ends for the present. Subsequently it will be continued to Lagos. It is stated that the westerly part of the route is free of the risk of yellow fever contagion through mosquitoes. The work of drainage and disinfection is concerned only with the easterly portion. In its present form the route measures about 1,800 miles and will be operated as soon as its sanitary certificate is in order.

The Lowest Infant Mortality on Record

The registrar general's provisional figures for 1935, which have just been published, show the lowest infant mortality on record. The death rate of infants under 1 year of age for the whole of England and Wales was 57 per thousand live births. The table gives the annual rates for the last ten years. The

Infant Mortality Rates

Year	England and Wales	County of London
1926	70	64
1927	70	51
1928	67	67
1929	74	71
1930	60	59
1931	66	61
1932	65	67
1933	64	60
1934	59	67
1935	57	68

1935 birth rate for England and Wales is 0.1 per thousand of population below that of 1934 and 0.3 above that of 1933, the lowest recorded.

Tetanus from Catgut Sutures

Cases of tetanus due to catgut sutures occur from time to time in spite of every care in sterilizing the catgut, which therefore seems never to be perfectly safe. The latest case occurred in a boy of 15 who died from tetanus after an operation in a hospital at Cambridge. Tetanus bacilli were found in the sutures. The medical superintendent said at the inquest that in his forty-one years' experience no similar case had occurred. The particular gut used in this case was derived from sheep on a farm in Australia where the land was specially treated in order to kill the tetanus bacillus in the soil. The manufacture of catgut in this country now is carried on under scrupulously clean conditions and is subject to regulations of the Ministry of Health, which regularly sends inspectors to witness the process.

Free Medical Care for Veterans

In France, every pensioned veteran, i. e., with an incapacity of at least 10 per cent is entitled to get the free care of the physician of his choice. The physician is paid by the government according to an official scale. A control bureau will prevent abuses. This bureau has just published its report. The number of beneficiaries are 856,427, of whom 453,654, or 53 per cent were treated. The total expenses were more than 114,000,000 francs, an average of 252 francs per payee. The doctor fees (including transportation fees) were 40 per cent of this sum. The cost of drugs is figured at 43 per cent, the hospital fees 10 per cent and the remainder, 7 per cent, administration charges. This means that the average paid for every veteran to every physician is 107 francs and that the average for each of the 17,000 physicians concerned is about 3,000 francs. Only ninety-four physicians received more than 20,000 francs in the calendar year 1935. As a matter of fact, the care given to the disabled veterans is a small benefit to the French general practitioner.

Aron's Reaction for Cancer

Beckre read before the Academie de medecine, a paper about Aron's test or reaction. This test initiated in 1933 and derived from Zondek's work is an adrenal cortex reaction. It consists in examining by biopsy, a part of the adrenal cortex of a rabbit and after three or four days injecting the rabbit

with a urinary extract Two days after the last injection the rabbit is killed and its renal cortex compared with the fragment taken in the first biopsy

Aron reports the results in 162 tests on 125 subjects, on whom his method was used for clinical purposes As the method depends on histologic interpretation, being a comparison between the cortex of the treated animal before and after the treatment, it was necessary not to let the pathologist be aware of the diagnosis in the cases studied Again, to make the chances even, the series of observations were mixed with positive and negative cases in equal proportions A strict control allowed the elimination of thirty-four of the 162 results, leaving an undisputable remainder of 128 reactions These were grouped under six notations negative, doubtfully negative, 1 e, no cancer, doubtful, +, ++ and +++, 1 e, cancer Thirty-five cases involved unquestionable instances of cancer The reaction was correct in thirty, three +++, ten ++ 9 + and eight doubtfully positive In five authenticated cases the reaction was negative It concerned one cancer of the pylorus, three of the stomach and one of the colon In all, the proportion of suspected and biologically confirmed cancers was 85 per cent Eighty-eight tests were made in noncancerous ailments plus 8 cancers operated on without any clinical evidence of relapse Seventy-eight reactions were negative and thirteen were doubtfully negative In ten cases, on the other hand, the reaction was + or doubtfully positive So the proportion of correct reactions was 89.3 per cent The whole amount of errors is consequently fifteen in 131 tests, or 11.7 per cent

These results are in favor of the specificity of the substance contained in the urine of the cancerous, regardless of the nature of the tumor The number of errors is related to technical difficulties, for this test requires an experienced pathologist, adequately equipped These considerations stand in the way of the practical adoption of Aron's technic, but its author is satisfied to have ascertained its principle, hoping that further improvements will permit the use of this new and important test by pathologists generally

Jubilee of Kaiser Wilhelm Society for Advancement of Science

Under the presidency of the physicist Prof. Max Planck, the Kaiser Wilhelm Society for the Advancement of Science celebrated, January 10, its twenty-fifth anniversary.

The creation of research centers in addition to the German scientific academies, universities and hochschulen, centers not strictly controlled by the government, had long been contemplated The expansion of official scientific enterprises in Germany necessitated the erection of a research institution devoted to special fixed scientific fields Besides, in many instances research activities had suffered because of the exacting nature of teaching duties in the hochschulen Then, too, the ability to teach is not the possession in equal degree of every research worker At length sentiment crystallized about the concept of a well appointed research institution staffed by competent specialists Since it was not subsidized by the government, this institution, in order to function with all possible freedom, must be established on a sound economic basis Funds for its maintenance therefore would be subscribed chiefly by enthusiastic private patrons of scientific progress The prosperous condition of the Germany of twenty-five years ago made possible the realization of such a project, so in 1911 at the suggestion of Wilhelm II, acting in cooperation with a group of men prominent in economic life, the Kaiser Wilhelm Society, an organization unique of its kind, was called into being on the occasion of the centenary of the University of Berlin Adolf

von Harnack, who served as president of the society from its founding until his death, was succeeded by Max Planck Substantial assistance came to the society from various sources its own members, industrial leaders, other wealthy donors, and the government

The society was divided into thirty-four organizations distributed throughout the reich with headquarters in Berlin-Dahlem Some of the institutes were devoted to more or less theoretical activities, for example, the institute of biology and that of cell physiology, both in Berlin-Dahlem, the institute of anthropology, human genetics and eugenics, the institute of biochemistry and, farther away, the well known Vogelwarte (ornithologic observatory) at Rossitten in East Prussia

Another group of research stations grapple with important practical problems Of special benefit to the industrial worker is the institute of occupational physiology at Dortmund, which concerns itself with the physiology, pathology and hygiene of work There in particular a systematic study is made of the questions of fatigue, of decent and suitable working conditions of the relationship between types of work and types of diet and so on, the institute thus functioning in the interest of all as an objective and impartial tribunal The institute for research in cerebrology at Berlin and the German research institute at Munich also carry on valuable activities

It is the business of the hydrobiologic institution constantly to seek out new and promising paths of research, while its practical function has to do with increasing the stock of fish in our waters, an important factor in the nation's food supply The German entomologic institute occupies an analogous position, its work combining the theoretical and the practical While making an objective study of how products worth millions of marks are each year destroyed by insects, the institute at the same time directs a substantially successful campaign against these pests The work program of the institute for research in stock breeding at Hünneberg is carried out in much the same way This institute is especially concerned with the fundamentals of crop sowing and animal husbandry

There is a third group of research institutions in which problems created by the needs of industry are dealt with Thus there is an institute for coal research at Mülheim (Ruhr), an institute for metallurgic research and, separate from the last named, an institute for iron research An institute for silica research helps to solve the technical problems of the ceramics, the glass and the cement industries, while an institute for leather research occupies itself with the fundamentals of the leather industry, including the chemistry and colloid chemistry of tanning technic These represent but a few examples of a much longer list of important research institutions

As the activities of the Kaiser Wilhelm Society embrace both the theoretical and the practical, so the central administration keeps free from onesidedness, for, apart from the institutions mentioned, the society serves the cultural interests by supporting special sociological scientific societies devoted to esthetic, cultural and legal studies Further units of the Kaiser Wilhelm Gesellschaft are quasynational, quasi-international in character, for example, the Rovigno zoological station, a German-Italian institution for oceanographic research, the biologic station at Lunz (Lower Austria), and finally the Jungfrauoch High Alpine research station in Switzerland, maintained for common research activities by Germany, France, England, Belgium, Austria and Switzerland

The fact that through the evil days that followed the war even with inflation and revolution the work of the society never completely came to a standstill, and that under three different types of government the organization has been able to function and to expand, bears witness to its vitality In every field of learning the notable achievements of the Kaiser Wilhelm Gesellschaft have been acknowledged

This was well expressed in the jubilee celebration in which numerous friends of science participated. Among others the American ambassador stressed particularly the cordial international relations maintained by the society. The president of the Kaiser Wilhelm Society, Professor Planck, called attention to the substantial assistance rendered by the government of the Reich and praised the generosity of the Rockefeller Foundation, recently expressed again in the gift of a new building for the Kaiser Wilhelm Institute of Physics. Of the guests lodged in the society's Harnack House (a building set aside for the accommodation of visitors), the Americans outnumbered all other foreigners (a total of 172 guests of whom one third were foreigners was accommodated at the house during the summer semester of 1935). Two scholarly festschriften were published in connection with the jubilee. Among the notable anniversary papers was one by Professor Debye, director of the Kaiser Wilhelm Institute of Physics, on the structure of liquids, another by Professor Bruns, on German art in Italy, was also of interest.

The problem of the Gleichschaltung of learned institutions also came to the fore in the course of the jubilee. Professor Planck in his commemorative address mentioned the late Nobel prize winner Haber, who had been director of a Kaiser Wilhelm Institute and whose ingenious nitrogen synthesis was of great service to the German prosecution of the war. The Reichsminister of Education, Rust, in an after dinner speech again referred to Haber, who was a Jew, without mentioning him by name. While acknowledging the great service performed by this man, he said, one must in such cases differentiate between the scientist and the person. Rust further stated as the fundamental ideal for scientific research that it be carried on within the wind-proof shelter of liberally endowed institutions, freed from restraint and separated from teaching activities. But already the experience of the World War had shown that research could not always maintain this character. It was then for the first time that the Kaiser Wilhelm Society, departing from its original purpose, bowed to necessity and acquired the power to "carry on" this power which alone underlies all existence. The form this power may take is immaterial. History shows time and again how forms may be shattered, the form of the Kaiser Wilhelm Society too may disintegrate. (It is perhaps interesting to note in this connection that the society is being assailed by the party organs because of its scientific objectivity and reservedness in political matters.)

Genital Tuberculosis

As he reported to the Berlin Medical Society, Dr. Caffier has observed at the woman's clinic of the University of Berlin an increase of genital tuberculosis in recent years. He attributes this less to the improvement in diagnostic aids than to the more frequent performance of laparotomies such as are undertaken on account of sterility, for example. The diagnosis of this type of tuberculosis is still more or less accidental. According to Caffier, microscopic examination is absolutely essential especially for the recognition of tubal tuberculosis, cystic tuberculous salpingitis and uterine and ovarian tuberculosis. Primary tuberculosis of the genitalia is a rarity (contrary to former opinion); it is chiefly a question of endogenous reinfection with hematogenous diffusion through general tuberculosis. Exogenous reinfection is not at all rare. Other present day therapeutic procedures besides operation include roentgen treatment and heliotherapy, the last named a prolonged and expensive but successful method.

In the other woman's clinic of the university the Charité the frequency of genital tuberculosis could not be observed. Perhaps also regional differences count for something in the dissemination of this disease; at any rate the matter of fact here related remains important.

The National Antituberculosis Congress

The fifth national congress for the crusade against tuberculosis was recently held in Rome under the chairmanship of Prof. Eugenio Morelli at the Istituto Carlo Forlanini. Professor Besançon, secretary of the International Union Against Tuberculosis, was present.

Prof. Bruno Biagi, president of the Istituto della previdenza sociale, spoke on insurance in tuberculosis and concluded that farmers, government officials and priests should be included in the benefits of compulsory insurance. This would diminish the expenses of provincial antituberculosis centers, which could then intensify the work in the dispensaries for the prevention of the disease. Another aspect in the problem of prevention of tuberculosis is the care of tuberculous mothers and their children.

The official topics dealt with the biologic, clinical, therapeutic and social aspects of tuberculosis.

Professor Petragliani, general director of public health, spoke on the chemical constitution of the tubercle bacillus. He studied the phenomenon of the decomposition of tubercle bacilli in their chemical constituents when treated by phenol, acetone and alcohol-ether. The particles of tubercle bacilli thus obtained have been tried with encouraging results as vaccines for the diagnosis, prevention and treatment of tuberculosis. They preserve antigenic characteristics, as has been proved by the results of the Bordet-Wassermann reaction, and lose them permanently, as has been proved by the results of tests *in vitro* and *in vivo* by the addition of small amounts of sulfuric acid to the vaccines.

Professor Micheli of Turin, with the roentgenologic collaboration of Professor Lupo, spoke on endogenous reinfection and exogenous superinfection in postprimary pulmonary tuberculosis. Exogenous superinfection is generally produced, as primary tuberculosis, by the air through the bronchial route. It is independent in its effects, of the origin of the inhaled tubercle bacilli. The statement that exogenous superinfection follows a direct route from the cervical lymphatic ganglions of the lung through certain routes pathologically opened, such as furuncles, eczema and the tonsils, has not been proved. The speaker believes that the name "postprimary tuberculosis" should be used instead of tuberculosis in adults, because the latter designation fails to make any reference to the primary infection. The clinical and roentgen examination of postprimary tuberculosis, verified by observations of the pathologic anatomy, have nearly settled the question of an endogenous origin of the condition. This statement is supported by the following facts: the persistence of the satellite ganglions of the primary infiltration as an almost constant source of infection and the frequency of tuberculous bacillemia and of the development of new pulmonary foci from a bacillary dissemination through the blood. The origin of phthisiogenic infiltration is now considered endogenous, the infiltration taking place through the blood, either directly or indirectly. In cases of the last mentioned group the infiltration takes place in clinically inactive old lesions, either healed or calcified. With regard to exogenous superinfection in persons clinically healthy who have overcome the primary infection, the results of recent researches prove that the danger of contagion exists also for those persons. The statement is confirmed by the increased frequency of infection in various familial and epidemiologic groups as well as by the frequent appearance of new lesions, including early tuberculous infiltration which are revealed by the roentgen examination of the thorax of these persons. The occurrence of a double infection in human beings with tubercle bacilli of the bovine and human types which is rare, supports the theory of exogenous superinfection. Therefore both the exacerbation of pulmonary tuberculous lesions and endogenous reinfection do not exclude the possibility of

William P. Orr Jr. * Lewes, Del., University of Pennsylvania Department of Medicine, Philadelphia, 1884, past president of the state board of health and the Sussex County Medical Society, for many years a member of the board of education, formerly medical officer in charge of the Delaware Breakwater Quarantine Station of the U. S. Public Health Service, on the staff of the Beebe Hospital, aged 78, died, January 9, of heart disease.

John Hamilton Revington, Chattanooga, Tenn., University of Tennessee College of Medicine, Memphis, 1914, member of the Tennessee State Medical Association and counselor of the third district, past president of the Chattanooga and Hamilton County Medical Society, fellow of the American College of Surgeons, served during the World War, aged 45, on the staff of the Baroness Erlanger Hospital, where he died, January 27.

Joseph Poland * Atlantic City, N. J., Jefferson Medical College of Philadelphia, 1907, past president of the Atlantic County Medical Society, for many years medical inspector of the city schools, at one time member of the medical staff of the Jewish Seaside Home, on the staff of the Atlantic City Hospital, aged 50, died, January 8, in the Temple University Hospital, Philadelphia.

James Newbegin Worcester, New York, Columbia University College of Physicians and Surgeons, New York, 1910, served during the World War, at one time assistant professor of clinical surgery, Cornell University Medical College, on the consulting staff of the Beekman Street Hospital, aged 51, died January 10, in the Presbyterian Hospital.

Wilbur Warren Williams * Coldwater, Mich., Eclectic Medical College, Cincinnati, 1915, University of Michigan Homeopathic Medical School, Ann Arbor, 1921, president of the Branch County Medical Society, aged 44, on the staff of the Wade Memorial Hospital, where he died, January 11, of cerebral hemorrhage.

Rufus Lee Rigdon * San Francisco, Cooper Medical College, San Francisco, 1887, clinical professor of genito-urinary surgery, emeritus, Stanford University School of Medicine, member of the American Urological Association, consultant in urology to the Lane Hospital, aged 76, died, January 21, of lobar pneumonia.

Julius Andrew Mood, Sumter, S. C., Medical College of the State of South Carolina, Charleston, 1879, member of the South Carolina Medical Association, veteran of the Spanish-American War, formerly mayor of Sumter and chairman of the city school board, aged 81, died, February 7, of carcinoma of the rectum.

William Sheldon Coons, Yonkers, N. Y., University of the City of New York Medical Department, 1891, health commissioner of Yonkers, on the staff of St. John's Riverside Hospital and director of the Gray Oaks Hospital, aged 66, died, January 17, of embolism, following an injury to the knee.

Monroe Aaron Maas * Selma, Ala., Johns Hopkins University School of Medicine, Baltimore, 1911, served during the World War, on the staff of the Vaughan Memorial Hospital, formerly on the staff of the Selma Baptist Hospital, aged 47, died, January 29, of carcinoma of the pancreas.

Hamilton Rinde, Middletown, Conn., Johns Hopkins University School of Medicine, Baltimore, 1908, member of the American Psychiatric Association and the Connecticut State Medical Society, on the staff of the Connecticut State Hospital, aged 56, died, January 3, of coronary thrombosis.

Henry Theodore Pope * Lumberton, N. C., North Carolina Medical College, Davidson, 1894, past president of the Robeson County Medical Society, on the staffs of the Baler Sanatorium and the Thompson Memorial Hospital, aged 64, died, February 12, of influenza and heart disease.

Wiley Egan Woodbury * New York, Detroit Homeopathic College, 1906, member of the Michigan State Medical Society, served during the World War, formerly director of the Fifth Avenue Hospital, aged 55, died, January 6, in St. Joseph's Hospital, Phoenix, Ariz., of pneumonia.

Luther Lochman von Wedekind * Medical Director, Captain, U. S. Navy, retired, New York, College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1886, entered the navy in 1888 and retired in 1928, aged 71, died, Nov. 24, 1935, of chronic myocarditis.

Francis Howard McCaskey * Rochester, Pa., Western Pennsylvania Medical College, Pittsburgh, 1901, past president of the Beaver County Medical Society, on the staff of the Rochester General Hospital, aged 64, died, Dec. 24, 1935, of cardiovascular renal disease.

Emmet Lee Fuller, Demopolis, Ala., University of Alabama Medical Department, Mobile, 1900, member of the Medical

Association of the State of Alabama, aged 61, died, January 16, in the Vaughn Memorial Hospital, Selma, following an operation for renal calculus.

Daniel Patrick Teter, Chicago, Baltimore Medical College, 1889, on the staffs of the Swedish Covenant Hospital and the Martha Washington Hospital, at one time medical warden at the Cook County Hospital, aged 69, died, January 9, of coronary thrombosis.

Daniel Carson Louchery, Clarksburg, W. Va., University of Maryland School of Medicine, Baltimore, 1880, member of the West Virginia State Medical Association, for many years a member of the staff of St. Mary's Hospital, aged 90, died, January 3.

Frank Edmund Luke, Chatham, Pa., Faculty of Medicine of Trinity College, Toronto, Ont., Canada, 1886, member of the Medical Society of the State of Pennsylvania, aged 72, died, January 7, of cerebral arteriosclerosis and cerebral hemorrhage.

Herbert Elias Kelly, Ida, Mich., University of Michigan Department of Medicine and Surgery, Ann Arbor, 1899, member of the Michigan State Medical Society, aged 62, died, February 6, in St. Vincent's Hospital, Toledo, of heart disease.

Nelson Alonzo Pennoyer, Kenosha, Wis., Hahnemann Medical College of Philadelphia, 1870, formerly medical superintendent of the Pennoyer Sanitarium, now known as St. Catherine's Hospital and Sanitarium, aged 86, died, Dec. 26, 1935.

Rolland Vincent Turner, Aurora, Ill., State University of Iowa College of Medicine, Iowa City, 1925, member of the Illinois State Medical Society, aged 37, died, January 23, in the Misericordia Hospital, Milwaukee, of Addison's disease.

Emory Chester Rebman * Austin, Minn., Northwestern University Medical School, Chicago, 1909, president of the Austin Clinic, on the staff of St. Olaf Lutheran Hospital, aged 50, died, January 7, of pneumococcal meningitis.

Charles Fulton Parker, South Windham, Maine, University of Vermont College of Medicine, Burlington, 1898, member of the Maine Medical Association, aged 66, died, January 1, of pulmonary embolism and bronchopneumonia.

Edwin G. Rust * Cleveland, Homeopathic Medical College, Cleveland, 1880, member of the American Academy of Ophthalmology and Oto-Laryngology, fellow of the American College of Surgeons, aged 78, died, Dec. 29, 1935.

Albert Patrick O'Leary, Big Timber, Mont., University of Michigan Department of Medicine and Surgery, Ann Arbor, 1898, member of the Medical Association of Montana, mayor of Big Timber, aged 64, died, Dec. 28, 1935.

William Henry Harrison Lewis, Fayette, Miss., Tulane University of Louisiana Medical Department, New Orleans, 1889, member of the Mississippi State Medical Association, aged 69, died, January 6, of pneumonia.

John Neuberger * Cleveland, Western Reserve University Medical Department, 1901, on the staffs of St. John's and the Lutheran hospitals, aged 60, died, January 8, of carcinoma of the rectum with metastasis to the liver.

George McIntyre Campbell * Akron, Ohio, Western University Faculty of Medicine, London, Ont., Canada, 1904, aged 55, on the staff of the People's Hospital, where he died, January 14, of cerebral hemorrhage.

Alfred Edwin Wadsworth, Malverne, N. Y., Long Island College Hospital, Brooklyn, 1891, died, January 15, in the Meadowbrook Hospital, Hempstead, of injuries received when he was struck by an automobile.

Samuel Cary Lightner, Kingston, Ohio, Medical College of Ohio, Cincinnati, 1886, aged 74, died, January 7, in the Mount Carmel Hospital, Columbus, following amputation of the leg for diabetic gangrene.

John Lewis Van Tine, Philadelphia, Hahnemann Medical College and Hospital of Philadelphia, 1893, associate professor of materia medica at his alma mater, aged 68, died, January 14, of cerebral hemorrhage.

James Townley Upjohn, Kalamazoo, Mich., University of Michigan Department of Medicine and Surgery, Ann Arbor, 1888, formerly state senator, aged 77, died, January 18, of angina pectoris.

William Edward McCaleb * Austin, Texas, Vanderbilt University School of Medicine, Nashville, Tenn., 1894, past president of the Travis County Medical Society, aged 64, died, Dec. 28, 1935.

William H. Wenger, Washington, D. C., College of Physicians and Surgeons, Baltimore, 1896, aged 66, died, January 29, of cerebral hemorrhage and cardiovascular renal disease.

Clarence Alfred Hanson, Chicago, Loyola University School of Medicine, Chicago, 1926, member of the Illinois State Medical Society, aged 39, died, January 21, of coronary thrombosis

William T Rathbun, Colusa, Calif., University of California Medical Department, San Francisco, 1892, member of the California Medical Association, aged 66, died, Dec 28 1935

William Henry Hopwood, Smock, Pa. Jefferson Medical College of Philadelphia, 1877, member of the Medical Society of the State of Pennsylvania, aged 82, died, Dec 22, 1935

Henry Irving Marsden, Somerset, Pa., Medico-Chirurgical College of Philadelphia, 1898, member of the Medical Society of the State of Pennsylvania, aged 64, died, Dec 20, 1935

Ernest Kingsley McCown, Stanfield, Ore., University of Louisville (Ky.) School of Medicine, 1925 served during the World War, aged 43, died, Dec 19, 1935, of pneumonia

James Henry Bogan @ Mackinac Island, Mich., University of Michigan Department of Medicine and Surgery, Ann Arbor 1892, aged 69, died, January 21, of pneumonia

James T Hammonds, Stanford Ky., Barnes Medical College, St Louis, 1902 member of the Kentucky State Medical Association, aged 55, died, Dec 17, 1935

Sylvan Elzanie H Rhodes, St Louis St Louis College of Physicians and Surgeons 1920, aged 35, died, January 7, in the Deaconess Hospital, of pneumonia

Adah Epperson, Indianapolis Northwestern University Woman's Medical School, Chicago 1901, aged 59, died January 15, of carcinoma of the stomach

Matthew T Love, Shelby, Ohio, Starling Medical College Columbus, 1884, aged 76 on the staff of the Shelby Memorial Hospital, where he died, Dec 23, 1935

James Douglas Robertson, Brookline Mass College of Physicians and Surgeons, Boston, 1894 aged 72, died, January 25, of hemiplegia and arteriosclerosis

Goldsmith P Robinson, Colorado Springs, Colo New York Homeopathic Medical College, 1877, aged 83, died, January 4, of carcinoma of the prostate

Henry Clay Grubb Linwood, N C., Temple University School of Medicine, Philadelphia, 1932, aged 29, died, February 10, of a self inflicted bullet wound

Albert G Grubb, Lagrange, Ind College of Physicians and Surgeons of Chicago, 1892, aged 73, died, January 12, of chronic nephritis and myocarditis

Clyde Leslie Van Patten, Cedar Rapids Iowa Hahnemann Medical College and Hospital, Chicago, 1911, aged 48, died, Dec 13, 1935, of pneumonia

Jacob Darwin Pines, Philadelphia, Hahnemann Medical College and Hospital of Philadelphia, 1892, aged 75 died, January 7, of coronary occlusion

Thomas Morris Strong, Boston, New York Homeopathic Medical College 1871, aged 87, died, Dec 17, 1935 in the Forest Hills Hospital

Otto William Starb @ Birtlett, Ill College of Physicians and Surgeons of Chicago 1888, aged 78, died, January 9 of coronary thrombosis

Browder Gaines, Louisville Ky Hospital College of Medicine Louisville, 1906, aged 58, died, January 3, in Adairville, of lobar pneumonia

Elmer E Dunkelberg, Wolfcreek Wis State University of Iowa College of Medicine Iowa City, 1886, aged 74 died, Dec 31 1935

Mansfield William Warner, Atlanta Ga Meharry Medical College Nashville, Tenn, 1914 aged 49, died January 9 of pneumonia

William Frederick Park, Amherstburg Ont Canada University of Toronto Faculty of Medicine 1893, aged 64 died January 3

Robert Harris Orr San Francisco University of California Medical Department, San Francisco 1896, aged 60, died Dec 26 1935

Frederick Henry Kalbfleisch Kitchener Ont Canada Trinity Medical College, Toronto 1888 aged 70 died Dec 13 1935

Theodore James Park, Amherstburg Ont Canada University of Toronto Faculty of Medicine 1879 died January 1

Isaac Newton Moyers Speedwell Tenn Tennessee Medical College Knoxville 1890 aged 76 died Dec 31 1935

Caroline Sophia Brown Toronto Ont, Canada, Trinity Medical College Toronto 1900 aged 73 died January 11

TREATMENT OF MILK ALLERGY

To the Editor —In his paper entitled "The Treatment of Milk Allergy and Its Basic Principles" (THE JOURNAL, Sept 21, 1935) Dr Bret Ratner makes several statements which either directly or by implication do not seem to be entirely in accord with fact. Since these statements concern investigations by us we feel that a reply is necessary.

On page 934 Dr Ratner says "Moro and Bauer first described cases of marasmus due to milk intolerance and showed that this condition could largely be attributed to immunologic disturbances resulting from the entrance of milk protein into the blood stream. Schloss and Worthen and Schloss and Anderson in America amplified this concept."

In the paper quoted by Dr Ratner, Moro found that blood taken post mortem from an atrophic baby contained a high titer of precipitin for cow's milk. A reasonably literal translation of Moro's comments on this case is as follows: The presence of intensely active (*avksam*) precipitins allowed the conclusion that large amounts of milk protein must have passed through the intestinal wall into the blood stream at some time prior to death. He stated, however, that he was very unwilling to draw widespread conclusions from this one case and could not feel justified in concluding that the circulating cow's protein caused the atrophy or made it more severe. He expressed the opinion that it was much more likely that the atrophy and the increased permeability of the intestine for proteins were results of the functional gastroenteric disturbance or of the excessive overfeeding or both. It is therefore very difficult to understand how any reader of Moro's paper can state that he described a case of marasmus due to milk intolerance.

Bauer discussed in some detail the then current opinion of some pediatricians that cow's milk protein could prove harmful to infants. He stated that for two years he had investigated the blood of infants artificially fed or suffering from gastroenteric disease, with essentially negative results. He then described a positive precipitin test and positive complement fixation test for cow's milk protein in the blood of a 1,700 gram premature baby who had died after suffering from malnutrition and diarrhea. In commenting on his case, Bauer stated that he believed that he had proved conclusively the occurrence of foreign protein in the blood of an infant and that it remained for further investigations to determine definitely the pathologic significance of these results.

Here again one can hardly agree with Dr Ratner that Bauer described a case of marasmus due to milk intolerance or that this case any more than that of Moro showed that marasmus "could largely be attributed to immunologic disturbances resulting from the entrance of milk protein into the blood stream."

The statement of Dr Ratner that the investigations of Schloss and Worthen and of Anderson and Schloss amplified the concept which he, Dr Ratner, attributed to Moro and Bauer carries the intimation that these investigations were merely confirmatory, to those of Moro and Bauer and permitted the same conclusions. Let us examine the facts.

The investigation of Schloss and Worthen was merely a demonstration of the passage of egg or milk protein through the intestinal wall of infants suffering from diarrhea or severe malnutrition. In the summary and conclusions of their paper, Schloss and Worthen say: "These results demonstrate the possibility that certain nutritional disorders in artificially fed infants may be due to the biologic character of the food although they obviously give no direct evidence to support such a view." Anderson and Schloss reported serologic evidence showing that cow's milk protein almost regularly entered

the circulation of marasmic infants fed on cow's milk. One of the most important differences in the results of their investigations from those of Moro and Bauer was dependent on technique. They found, as others, including Moro and Bauer had found, that satisfactory precipitin tests could not be carried out with ordinary milk, owing to its turbidity in even very dilute solution. Only very heavy precipitates could be detected. After experimenting with various preparations of cow's milk protein, Anderson and Schloss found that a commercial brand of dried fat free milk gave clear solutions in which slight precipitates could be detected readily. It was thereby possible to make repeated tests for precipitin in the blood of living marasmic infants over long periods of time in the attempt to relate the absorption of antigenic cow's milk protein to the nutritional state of the patient. Anderson and Schloss were able to demonstrate precipitin for cow's milk protein in the blood of eighty of the ninety-eight infants examined. We believe that this was more than a mere amplification of Moro and Bauer's postmortem demonstration of the enteral absorption of cow's milk protein by two infants who had suffered from marasmus in one case and diarrhea in the other. We also wish to emphasize that neither our results nor those of any one else have demonstrated a causal relationship between the enteral absorption of incompletely digested cow's milk protein and marasmus. Such absorption may be purely secondary or coincidental.

To the casual reader, Dr. Ratner's comment on the paper of Anderson, Schloss and Stuart in the last paragraph of page 936 might give the impression that he wishes to intimate that the experiments were performed with impure preparations of casein. In this paper investigations were reported demonstrating immunologic similarity of the casein of cows, human and goat's milk, which as a matter of fact had been demonstrated before.

The preparations of casein were carefully isolated by the method of Van Slyke and Baker and were, we believe, pure. But even if these caseins did contain traces of whey protein the conclusions would not have been altered. It is our belief that Dr. Ratner must have known this and that his reference to impure preparations did not refer to our experiments. We believe that he wished to imply that the statement in the opening paragraph of our paper that the immunologic relationship of the different caseins is of clinical importance must be wrong and that this belief on our part was probably due to the performance of skin tests with caseins contaminated with whey protein despite the fact that in the paper of Anderson, Schloss and Stuart no reference whatever was made to such tests. Assuming that our interpretation of Dr. Ratner's meaning is correct, we wish to make the following comments:

We agree entirely with Dr. Ratner that the whey proteins are of paramount importance in idiosyncrasy to cow's milk and only with comparative infrequency is casein at fault, but what we do wish to take issue with him on is the insinuation that our belief that idiosyncrasy to casein may be of importance is due to the fact that we have been misled by tests with impure casein. We fully realize the danger of drawing erroneous conclusions by the use of contaminated test preparations but we have from time to time carefully studied cases of idiosyncrasy to casein in which such criticism is patently invalid. Three cases will be cited briefly.

CASE 1—A breast fed baby, aged 3 months, developed eczema when he was 2 months of age. Scratch tests with a 1 per cent solution of casein in twentieth-normal sodium hydroxide caused very marked reactions evidenced by wheals varying from 2 to 3 cm in diameter. (This casein was prepared by precipitation with dilute acetic acid, repeated washing of the centrifuged precipitate with distilled water, solution of the precipitate in a weak solution of sodium hydroxide and reprecipitation by acetic acid. Washing of the precipitate solution by aid of sodium hydroxide and reprecipitation by acetic acid as outlined were

carried out five times. The final precipitate was carefully washed with distilled water, centrifuged, washed with alcohol and ether and dried in a current of warm air.) A 1 per cent solution of albumin from cow's milk gave on one occasion a negative scratch test and on two occasions equivocal reactions. (This albumin was prepared by first removing the casein from diluted cow's milk by precipitation with acetic acid. The filtrate was centrifuged to remove small particles of casein and the globulin precipitated by one-half saturation with ammonium sulfate. The albumin was thrown down by full saturation with ammonium sulfate. The resulting precipitate was purified by solution in distilled water and reprecipitation by saturation of the resulting solution with ammonium sulfate. This procedure was repeated three times. The final precipitate was dissolved in the smallest possible amount of distilled water, dialysed to remove ammonium sulfate, reprecipitated by pouring into a large volume of acetone and dried in a current of warm air.) A scratch test with casein from goat's milk in 1 per cent solution caused a wheal 2 cm in diameter. A 1 per cent solution of albumin (prepared by the same technique as outlined for cow's milk) from goat's milk provoked a slight erythema about 0.5 cm in diameter but no wheal. It therefore seems evident that this patient showed cutaneous sensitivity to casein not due to contamination with albumin.

CASE 2—A boy aged 2 years was known to be sensitive to cow's milk. When cow's milk was ingested the patient usually developed slight urticaria around the mouth, at times generalized urticaria and on one occasion an attack of asthma. The symptoms were previously more severe than at the time when the patient was first seen. Scratch tests gave very marked reactions to cow's milk.

Marked cutaneous reactions were caused by scratch tests with a 1 per cent solution of casein. As a rule, an irregular wheal from 1 to 2 cm in diameter surrounded by a zone of erythema occurred. Skin reaction to lactalbumin was much more intense than to casein. Usually the wheals were from 3 to 4 cm in diameter and were surrounded by a wide zone of erythema. It so happened that the sample of casein used in these skin tests had been employed in other investigations and its purity was established by immunologic tests. These tests were briefly as follows:

One cc of a 1 per cent solution of this casein was given to each of four guinea-pigs by intraperitoneal injection. Twenty days later the intraperitoneal injection of 3 cc of a 1 per cent solution of cow's milk albumin did not cause anaphylactic shock, but an injection of 3 cc of a 1 per cent solution of casein two days later caused severe shock.

This casein did not cause anaphylactic shock when given by intraperitoneal injection to three guinea-pigs sensitized nineteen days before the milk albumin. Their sensitization to milk albumin was demonstrated by the occurrence of shock when given an intraperitoneal injection of albumin from cow's milk two days later.

Although this patient was markedly sensitive to cow's milk albumin, it seems very clear that he was also sensitive to casein from cow's milk.

CASE 3—A baby, 3 months of age, had been entirely breast fed. Cow's milk was offered at this time as a supplementary feeding. Only about 30 cc of 50 per cent dilution of cow's milk was taken. Within a few minutes he vomited. This recurred several times within an hour and soon severe diarrhea developed. Seven profuse, watery stools were passed within two hours and the baby showed moderate prostration. Similar symptoms appeared after each attempt to feed cow's milk even though as little as 20 cc was taken. There were no cutaneous or respiratory manifestations. On two occasions, goat's milk caused the same disturbances. All skin tests to both cow's and goat's milk were negative.

In the attempt to determine the milk proteins that caused the reaction the following experiments were made:

1 The ingestion of 5 cc of a 1 per cent solution of the albumin of cow's milk caused severe gastrointestinal symptoms. (This albumin was prepared by the same procedure as that used in case 2.)

2 The ingestion of 30 cc of a 1 per cent solution of cow's milk casein that had been serologically tested and was of the

same batch that caused vomiting and diarrhea in case 2. This test repeated five days later was followed by the same symptoms. It seems quite evident that this patient was sensitive to both albumin and casein from cow's milk.

In spite of Dr. Ratner's forceful expression of his views, we believe that we have sufficient evidence to warrant the conclusion that human beings can be allergic to pure casein from cow's milk.

URTICARIA OF UNKNOWN ETIOLOGY

To the Editor—A white man aged 28, a service station attendant, first came to me on April 30 with a case of hives. He had the first attack six years ago and another attack one year later thereupon skipping two years before another attack occurred. On previous attacks injections were given by one of our leading dermatologists and the attack subsided. No result was obtained this time. The patient changed doctors and was given autohemotherapy (two injections in each arm). No change in the condition resulted for better or worse; he has been taking amylal and ephedrine and also phenobarbital with no result. He was tested for allergy and responded to nearly everything but I do not believe that he had received any of the extracts. At first the wheals were large measuring from 1½ to 2 inches in diameter. Now they are smaller measuring perhaps one-half to three-fourths inch. They last only about half an hour and disappear. When new crops come out they usually come out in the same places as the previous ones and appear to be following a nerve. He has two that appear quite regularly, one in the bend of each elbow and one on the palmar surface of the left wrist. They change from white to red, itch and burn, are worse after a hard day's work with interrupted sleep and appear to be better that is are not so numerous or may not appear at all if he has a good night's sleep. My first prescription for him was resorcinol 3 grains (0.2 Gm.) in sufficient water to dissolve and tincture of nuxvomica 2 drachms (7.5 cc.) in elixir of lactopeptin sufficient to make 4 ounces (120 cc.) to be taken in a dose of 1 drachm (4 cc.) every three hours. This was followed by improvement but from that time on nothing seems to have made any impression. He is now taking A. M. S. solution (Raymer) which contains potassium arsenite, potassium chlorate, potassium sulfate and dilute hydrochloric acid. He takes this in 15 drop doses three times a day. There is nothing in his diet that seems to make any difference. He has eliminated eggs, milk, cheese, tomatoes, shell fish and various other articles but there has been no difference in his condition. He has noticed that playing golf seems to bring on an attack while he is playing. Any information you may be able to give will be greatly appreciated.

MD, New York

ANSWER—It must be stated in the beginning that the determination of the etiology of a given case of urticaria by means of skin reactions is usually disappointing. Positive reactions of various kinds are usually found because the individual with hives is usually an allergic individual. However, the antigens that give the positive reactions in a given patient are not necessarily the causative factors of the urticaria. It should be remembered that the materials causing the urticaria, particularly foods, may be ingested many hours before symptoms develop. Since that is the case, it should not be expected that applying such substances by means of skin tests will be followed by positive reactions within the comparatively short time during which a skin test is observed. Besides the skin test affects the superficial skin layers while hives are produced when the antigen reaches the lower skin layers.

The usual therapeutic measures for urticaria have been fairly well carried out in the patient under discussion. In some patients symptoms are prevented by taking peptone mixtures half an hour before meal times. Elimination diets are sometimes successful.

It seems significant in the history that the patient's symptoms are aggravated by a hard day's work, interrupted sleep and playing golf. He is better after a good night's sleep. All this indicates that the patient's symptoms originate during physical effort, for instance during golf and the exertion of a hard day's work, and that these manifestations are improved by rest. This agrees pertinently with Duke's contribution to physical allergy. He has demonstrated that many of the manifestations of allergy can be produced by hypersensitiveness to physical agents such as heat or cold. Allergy on the basis of heat or cold may reproduce in all particulars the manifestations

of allergy due to foods, inhalants and pollens. This conception suggests that the patient should be acclimated to heat by alternate exposures to heat as from a heat lamp and cold by ice rubs, the process being repeated several times and the treatment being carried out daily.

CHRONIC GONORRHEAL INFECTION

To the Editor—A married man about 30 years of age contracted a gonorrheal infection four years ago. He went to his doctor who diagnosed it as mentioned. Treatment consisted of tablets and capsules by mouth and solution for home irrigation. The discharge ceased after a few weeks. The following September the discharge again appeared and it has done every September since the original infection. Last September was my first contact with the patient. The discharge looked to be quite typical but the state laboratory returned a consistent negative. However, under National Drug Neisser Combined Vaccine the trouble cleared. Now for the third successive September the discharge has appeared—a rather thick yellow nonmucoous secretion. I have sent smears to the state laboratory and plan to send at least three. He states that there has been no infection other than the primary one. Of course my impression is that the condition is a chronic gonorrheal infection. Is this reasonable? Assuming this diagnosis to be correct, what is the latest accepted treatment? How can the annual September flare up be accounted for?

HARRY W. PERRIN, MD, Lishon, N. H.

ANSWER—The assumption that the patient in question is suffering from a chronic gonorrheal infection may be correct. The exact method of examination of the discharge is not stated. Recent experience has shown that cultures obtained from the urethral discharge, when the material is obtained with proper precautions, are accurate in more than 90 per cent of cases. The result of such a culture would therefore be of great value in this case, since smears frequently are negative when cultures are positive.

It would be logical to assume that there is a chronic prostatic infection present, which is keeping up the recurring discharge. A study of the prostatic secretion should be made as well as a urethroscopic examination and a thorough search for foci in the teeth and tonsils.

In case evidence of prostatic infection exists, the usual treatment consisting of vigorous prostatic massage and instillations into the deep urethra, usually brings good results. An abscess associated with first infection of the prostatic ducts may be a factor. In the hands of most observers vaccine has not been found to be of great therapeutic value. In case of persistent gonorrheal infection hyperpyrexia, particularly with the Simpson-Kettering apparatus, may be indicated. This form of treatment has been highly successful in clearing up persisting infection with *Neisseria gonorrhoeae*.

The seasonal recurrence of urethral discharge is frequently observed and is difficult to explain. However, there must be individual rather than climatic factors present to account for it.

LIMBER NECK AND POLIOMYELITIS

To the Editor—Can the disease in fowl commonly known as limber neck be transmitted to man? If so is the result similar to acute poliomyelitis? I have seen demonstration of transmission from fowl to small animals with resulting paralysis of their hind limbs. From this I had the impression that the two diseases were identical and on this ventured a prediction that a family of children having played in a chicken yard in which limber neck existed would become afflicted with the disease. I wasn't surprised when after a few weeks three of the children developed infantile paralysis. Since then I have seen another case of the disease in a young girl and on investigating found chickens with limber neck in a neighbor's yard. It is difficult for me to believe that this experience will have to be explained as a matter of coincidence. I should like to know whether it has been definitely established that they are two distinct diseases.

GUSTAV LUDWIGS, MD, East St. Louis, Ill.

ANSWER—Limber neck is a condition commonly seen in chickens. It is characterized by a paralysis with a peculiar weakness of the neck muscles and is due to the botulinus toxin.

Graham Brueckner and Pontius (Bull. 207, Kentucky Agricultural Station, June 1917) have reported a number of outbreaks of so-called forage poisoning or cerebrospinal meningitis of horses due to the toxin of *Clostridium botulinum*. It was further shown that the toxin of one type of *Clostridium botulinum* causes cases of limber neck in chickens. Chickens are readily susceptible to the toxin of the type A organism, developing limber neck but they are refractory to the type B toxin. *Clostridium botulinum* is widely distributed in nature and is found chiefly in the soil, in the feces of hogs in moldy hay and in damaged fruits and vegetables. Type A organisms are more frequently found in the western part of the United States and type B in the eastern part.

Epidemiologic evidence from time to time has seemed to implicate animals in the spread of some of these infections. Poliomyelitis has been associated in various reports with dogs,

cats, chickens and colts T G Hull (Diseases Transmitted from Animals to Man, Springfield, Ill, C C Thomas, 1930, p 247) investigated an epidemic of paralysis among hogs on a farm where two children were sick with poliomyelitis, but histologic examination of the spinal cord of the hogs revealed no evidence to indicate that the disturbance was poliomyelitis. In another instance the examination of the colts proved that the paralysis was apparently due to a nutritional deficiency. W H Frost (Bull 90, Hyg Lab U S P H S 1914) investigated the connection of paralyzed dogs, chickens and rabbits with the epidemics of poliomyelitis in Iowa in 1910 and in Cincinnati in 1911 but found no evidence to support the contention that such animals were suffering from the disease or acting as carriers.

From the foregoing it is apparent that the paralysis in chickens is due to the botulinus toxin and is independent of the paralysis due to poliomyelitis seen in children. However, it is possible that a paralysis in children simulating poliomyelitis may be due to the same toxin that is producing the paralysis in chickens or the so-called lumber neck.

GASTRO-INTESTINAL ABSORPTION—ABSENCE OF PAIN IN ULCER WITH ACHYLIA

To the Editor—I would appreciate reference information as to research work done on the following subjects: 1 Shortages of resorption of products of digestion in either health or disease. 2 Why is an achylic stomach with an ulcer free from pain?

ARTHUR A KIRCHNER M D Los Angeles

ANSWER—1 There has been such extensive literature published on "absorption from the gastro-intestinal tract during health and disease" that it is possible to cover the subject but briefly in these columns.

Following the observations of Beaumont (Experiments and Observations on the Gastric Juice and the Physiology of Digestion, Plattsburgh 1833) that gastric acidity decreased with infection or fever, patients were starved as a rule. In 1912 Eugene F Du Bois (The Absorption of Food in Typhoid Fever *Arch Int Med* 10 177 [Sept.] 1912) confirmed work published previously by the Russians and demonstrated the advantages of a high calorie and nutritious diet for typhoid patients. This changed the previously accepted dictum of "starve a fever" and stimulated study of gastro-intestinal absorption under varied conditions. The following references are submitted as a preliminary bibliography.

Bridges M A Dietetics for the Clinician Philadelphia Lea & Febiger 1933
Alvarez W C Nervous Indigestion New York Paul B Hoeber Inc 1931

2 The causes of ulcer pain are not completely understood as yet. Alvarez (The Mechanics of the Digestive Tract) summarizes the more commonly accepted theories as follows:

Carlson (Contributions to the Physiology of the Stomach. The Origin of the Epigastric Pains in Cases of Gastric and Duodenal Ulcer, *Am J Physiol* 45 81 [Dec.] 1917) believes that an increased sensitivity of the nerve endings changes the normal hunger contraction distress to the pathologic hunger pains associated with ulcer.

Palmer (The Mechanism of Pain in Gastric and Duodenal Ulcers *Arch Int Med* 38 603 [Nov.] 1926) concludes that in 90 per cent of the patients the chemical irritation (hydrochloric acid) is the only factor producing the ulcer distress in the remaining 10 per cent muscular contractions may be a factor.

Lea (Contributions to the Physiology of the Stomach. The Causes of Gastric Secretion Their Practical Significance and the Mechanisms Concerned *THE JOURNAL*, Sept 19 1925, p 877) theorizes that the intermittent type of ulcer pain is prob-

ably due to peristalsis or local spasm occurring at the site of the ulcer in muscle of changed tonicity. The continuous type of distress is due to congestion, edema and inflammatory reaction about the ulcer, all of which lower the threshold for stimuli. The role of the acid is to irritate the nerves and to increase the edema about the ulcer.

With these theories as a basis, it may be concluded that there would be no ulcer pain in achlorhydric ulcer patients because acid irritation would be absent.

SENSITIVITY TO PHOTOGRAPHIC SOLUTIONS

To the Editor—Please let me have any available literature on dermatitis resulting from contact with elon hydroquinone chrome alum hardener and acid hardening fixing bath used in the developing of photographic plates. The solutions used in the case under discussion were:

- | | | |
|---|-----------------------------|----------------|
| 1 | Elon hydroquinone developer | |
| | Water | 15 liter |
| | Elon | 31 Gm |
| | Hydroquinone | 59 Gm |
| | Sodium sulfite | 90.0 Gm |
| | Sodium bisulfite | 21 Gm |
| | Sodium carbonate | 11.5 Gm |
| | Potassium bromide | 17 Gm |
| | Borax | 8.0 Gm |
| 2 | Chrome alum hardener | |
| | Water | 4 liters |
| | Potassium chrome alum | 120 Gm |
| 3 | Acid hardening fixing bath | |
| | Water | 2 liters |
| | Sodium thiosulfate | 480 Gm |
| | Sodium sulfite | 30 Gm |
| | Acetic acid | 96 cc 28% pure |
| | Potassium alum | 30 Gm |

The patient working in these solutions with unprotected hands first noticed a rash on the hands and forearms. The rash rapidly spread to the rest of the body and was accompanied with severe itching. The rash resembles that of pityriasis. After ten days the rash is fading and the hands and fingers are scaling extensively.

JAMES L HACKETT M D Emporium Pa

ANSWER—Sensitization to almost any substance can occur and almost any of the ingredients mentioned may be suspected but most of them are rarely troublesome, so that they are not likely suspects. Of elon, a brand of metol, and of hydroquinone no such kind words can be said. They should be suspected and tested first. Make a patch test by wetting a small piece of absorbent cotton in a solution of two parts of elon to 1,000 parts of water, place it on apparently normal skin of the patient, cover it with gutta percha, oiled silk or oiled paper, and fasten with adhesive tape. Make a similar patch test with hydroquinone four parts per thousand parts of water. The same may be done with any other ingredient that may be suspected, using about the strength in which it is present in the mixture. Allow these to remain for forty-eight hours unless marked itching or burning develops in a shorter time. Remove the patches and read the results. A decided dermatitis under the pledget of cotton is recorded positive. Dermatitis under the edges where the covers touched the skin or under the adhesive tape, indicates sensitization to these substances.

If any of the ingredients of the developing or hardening baths give a positive reaction, it must be tested again. A second positive reaction indicates the offender.

Because metol is so often the cause of such a dermatitis, Kodolon, *p* amino phenol oxalate, a substitute recommended by the Eastman Kodak Company, the makers of elon may well be tested at the same time in the hope that it will be found nonirritating. The metol-hydroquinone developer is so much better than most others that photographers will try in many ways to continue its use, even though they are sensitized to it.

Bathing the hands frequently in 10 per cent aqueous acetic acid solution or rubbing them several times a day with a mixture of 32 parts of 28 per cent acetic acid, 16 parts of table salt and 64 parts of water is said to act as a preventive. Covering the hands with a thin film of ointment, paraffin or collodion has been tried with only partial success. The covering is imperfect and often makes trouble by smearing the films. For severe cases rubber gloves may be necessary. After removing them the application of 10 per cent acetic acid solution, or a 0.5 per cent solution of salicylic acid in 50 per cent alcohol may be helpful.

Freund (Prevention of Photographer's Dermatitis, *Wchnschr* 46 41 [Jan 13] 1933) mentions the difficulties and uncertainties of these methods and suggests instead of them a loop of string at two adjacent corners of the film. The technician handles the film by these loops, fastens them to a post on the especially made tray to keep them dry, and hangs

the film for drying by one of these loops. The author pictures and describes a mechanical device which he claims makes possible the formation of such loops very quickly, even in darkness. It is a simple and inexpensive method and deserves trial.

Treatment is not practical so long as exposure is repeated. After thorough rinsing in an acid solution, solution of aluminum acetate may be applied as a cool, wet dressing. The Eastman company recommends a bath of 100 parts water and two parts each of potassium permanganate and concentrated sulfuric acid. After this the stain may be removed with a solution of 2 per cent oxalic acid in water.

POSSIBLE RAYNAUD'S DISEASE

To the Editor—A woman aged 39, has what I am quite certain is early Raynaud's disease. The hands become painful and white when suddenly exposed to cold or immersed in cold water. The nails of the middle and ring fingers of both hands appear dark, dull and lifeless and have not had to be cut for about three months. The nails of other digits grow very slowly. The patient is in excellent health in other respects. I should like to know the latest and best treatment. How about foreign protein therapy or cervical sympathectomy? Kindly omit name.

M D Michigan

ANSWER—The diagnosis of Raynaud's disease in this case is open to some doubt. The attacks of ischemia on exposure to cold are typical of this disease. However, usually between the attacks the fingers are normal in appearance and in texture and in finger-nail growth. The fact that the patient is a woman favors the diagnosis of a vasospastic disorder rather than a diagnosis of organic occlusive disease of the vessels of the hands. It would be important to determine whether pulsations of both ulnar and radial arteries are present. If these are open, and if exposure of the hands to warmth restores them to a fairly normal condition a diagnosis of Raynaud's disease would be tenable. If restoration does not occur, one would suspect organic closure of the digital arteries. The patient seems too young to have arteriosclerosis obliterans. Thrombo-angitis obliterans is extremely rare among females. Embolic occlusion would have to be ruled out. If the condition is progressive, causing disability, sympathetic ganglionectomy would probably offer the best chance of ultimate relief. If surgical operation is not advisable, contrast baths, postural exercises, protection of the digits, injection of foreign protein and fever therapy might be used.

CEREBROSPINAL SYPHILIS

To the Editor—A white man aged 40, contracted syphilis six months ago. He received eight injections in the arm and none in the hip. He was then instructed to rest for six weeks. I saw him toward the close of this rest period for the first time. He had had a severe headache for several days. Examination showed a secondary optic atrophy. The spinal fluid was under greatly increased pressure and was clear. It contained 24 cells per cubic millimeter, mostly small lymphocytes and showed a positive Pandy, a one plus Kahn and a one plus Wassermann reaction. The blood Wassermann reaction was two plus and the Kahn two plus. The patient had gonorrhea about ten years ago. No blood tests were taken then. Is it possible that his present cerebrospinal syphilis is a result of an internal chancre at the time of the gonorrhea or is it more likely a recent infection with inadequate treatment? I started him on mercuric succinimide intramuscularly, one fifth grain (0.013 Gm.) three times a week. Do you think iodides are indicated simultaneously or would you wait and how long? When do you think it would be safe to start neoarsphenamine or do you believe tryparsamide would be better? I was planning a course of twenty injections of mercuric succinimide, one fifth grain three times a week, then bismuth salicylate, 2 grains (0.13 Gm.) twice a week for twelve injections and then ten injections of neoarsphenamine starting with 0.15 Gm. and gradually increasing every five days. He has high myopia and an ophthalmologist will determine his visual fields shortly. How often do you think it necessary to recheck his visual fields? Would iodobismutol be better than bismuth salicylate? Kindly give prognosis. Please omit name.

M D Illinois

ANSWER—The symptoms seem to indicate that there was an invasion of the central nervous system during the secondary stage of the patient's syphilis. One must assume that there has been inadequate treatment and institute intensive antisyphilitic therapy. Iodides should be used simultaneously, preferably in the form of intravenous sodium iodide. It is far better to use neoarsphenamine than tryparsamide in this type of syphilis. Bismuth salicylate is perhaps better than iodobismutol. It is quite likely that the disk changes are not due to secondary optic atrophy but to myopia.

The visual fields need not be regularly checked unless tryparsamide is used.

The prognosis cannot be determined this early, but active treatment at the present time would insure the best possible chances for the prevention of the severe tertiary neurosyphilis.

IDIOPATHIC HYPERTENSION IN PREGNANCY

To the Editor—Three months ago a multipara aged 26 came to me for antepartum examination. The last menstrual period was March 15. There are no present complaints. The patient has been feeling well since the last period. She had chickenpox in childhood but no other diseases or serious illnesses. She has been subject to occasional attacks of nausea and vomiting associated with headache since early childhood but these were of short duration. The first pregnancy was four years ago. When examined first in the early months of pregnancy her physician mentioned that her blood pressure was high; she thinks around 180. No treatment was instituted, however, and pregnancy continued normally, with no abnormal symptoms. She was delivered spontaneously at term after about eight hours of labor. Her health was good until the second pregnancy two years ago. During this time she had occasional attacks of headache and malaise but did not consult a physician until the end of the eighth month when vaginal bleeding was followed in a few hours by stormy labor pains. The bleeding and pains continued for about twelve hours when she was delivered of a dead fetus by forceps. Her health has been good until the present time. Examination when the patient was first seen showed the blood pressure to be 210 systolic, 120 diastolic. The heart was slightly enlarged to the left. A blowing systolic murmur was heard at the base and the apex. The heart rate was 90. There was no swelling of the ankles and there were no visual disturbances. The twenty-four hour urine showed a volume of 40 ounces, color light straw, specific gravity 1.020, albumin and sugar negative. Blood count and hemoglobin were normal. The patient was put to bed for two weeks and given three quarts of milk each twenty-four hours, orange juice and viosterol. At the end of two weeks the blood pressure was 190/120. She was allowed to be up about the house for about two hours a day and instructed to take a low protein and low salt diet. The blood pressure slowly rose to its original level in three weeks. She was put back to bed and allowed up only for meals. A low protein diet was continued. The bowels were kept regular with liquid petrolatum and milk laxatives. Bismuth subnitrate was given in a dosage of one teaspoonful of the powder twice daily. The patient continues to feel well except for an occasional headache followed by vomiting which promptly relieves it. The twenty-four hour output of urine averages around 66 ounces, albumin and sugar are negative, with an occasional hyaline cast. The specific gravity remains around 1.020. The occasional headache is described by the patient as feeling as if the head was too full. The blood pressure remains from 200 to 210/120. There is still no swelling of the ankles, dizziness or visual disturbances. Blood chemistry has not been done. I would appreciate your suggestion as to further treatment and the prognosis of this case. If eclampsia does not come on before the onset of labor I am afraid that increased blood pressure during labor may cause a cerebral hemorrhage.

N D Arizona

ANSWER—The patient evidently suffers from a condition that is being called, for the want of a better name, idiopathic hypertension, and in all probability a chronic cardiovascular disease is at the root of her trouble. The pregnancy seems to aggravate the existing condition and probably the patient is shortening her life by repeated gestations. The toxemia and premature labor of her second pregnancy, which probably ended with abruptio placentae, confirm these suspicions. Many accoucheurs would empty the uterus in such a case as this regardless of the period of development of the fetus, in order to prolong the woman's life. Recommendations for this particular case are absolute rest in bed, stimulation of diuresis by means of 250 cc. doses of 25 per cent dextrose intravenously and a diet without any salt whatever and consisting of fruit juices, nonprotein vegetables and cereals with from 25 to 30 Gm. of animal protein daily. When the child is viable a low or cervical cesarean section should be done under local anesthesia with Madlener's method of sterilizing the patient—crushing and ligation of the tubes.

RELIEF OF SYMPTOMS AT MENOPAUSE

To the Editor—A woman aged 35, the mother of one child, had both ovaries removed on account of cysts. I anticipate menopausal symptoms and wish to know what treatment you would advise to prevent this. Will she experience any sexual sensation? Do not mention name.

M D Oklahoma

ANSWER—Most women who have symptoms of the menopause can be relieved of some of their distressing disturbances. Some women can be relieved of all their symptoms, whereas other women are refractory to all treatment. The product that is helpful for most women who are in the menopause is an estrogenic substance. The commercial preparations of this product are known by such names as theelin, ammotin, progyon and menformon. The best way to administer the substance is by hypodermic injection deep into the muscle (the gluteus muscle preferably). These products can also be administered by mouth but the dose must be five times as great as when given intramuscularly. It is best to start with hypodermic injections of about 200 rat units every second day. After a number of injections have been given, the physician should increase or decrease their frequency and strength, depending on the effect the substance has on the disturbing symptoms. In nearly all cases in addition to the estrogenic substance it

is advisable to prescribe a mild sedative such as the bromides or phenobarbital. Many women who undergo the menopause retain their sex desires and sex gratification whereas others lose it temporarily or permanently. If a woman broods over this or over the change of life in general a few intimate conversations concerning a more optimistic view on life may prove helpful.

TREATMENT OF VARICOSE VEINS WITH ULCERS

To the Editor—In the treatment of varicose veins Unna's paste has been a standard remedy for many years. The directions for applying this paste state that it should be applied the entire length of the veins and that the paste should also be spread over the ulcerated regions unless there is too much weeping from the ulcer or ulcers. Of course the beneficial effect of the paste on an ulcer from which there is no great amount of fluid discharging appears obvious while the use of an elastic bandage such as is put over the paste and the gauze covering the paste can also be understood as a useful procedure but of what benefit is it to apply the paste along the entire course of the vein when over its greatest length there are no ulcers nor any suggestion of an ulcer likely to develop? Also when an ulcer is weeping excessively so that the Unna's paste cannot be applied over it what is the theory underlying the benefit that accrues to the ulcerated regions when only the non-ulcerated regions are covered with the paste? Also when it is intended to institute obliterative treatment is it necessary to wait until ulcers are healed before the treatment can be started? I know that there are a great many solutions recommended for injection in obliterative treatment and I have used a mixture of magnesium sulfate and sodium chloride with quite good results in all except one case out of a series of six the case that showed unsatisfactory results being one in which there were badly twisted veins which I finally had to ligate. As my experience with these cases was quite concentrated all within a short time and about four years ago may I ask whether in the meantime any other substance or substances besides the mixture mentioned and the often mentioned quinine and urea hydrochloride has been proved more and sufficiently often successful that such may be considered a standard treatment in the light of present knowledge.

M D Illinois

ANSWER—The correspondent would be interested in a pamphlet issued by the Committee on Varicose Veins of the American Medical Association based on the material shown at the Scientific Exhibit in Philadelphia. Unna's paste must be applied from the toes to the knee in every case. It affords elastic support to the dilated veins prevents back pressure and protects the limb from too much edema. Ulcers below veins with incompetent valves heal much faster when the stagnating column of blood is held back by the even pressure of a bandage or boot. When the ulcer is acutely inflamed or when secretion is active it is wise to apply several layers of gauze or a marine sponge over the ulcer, not only for even pressure but also to dispose of the secretion. In such cases the boot may have to be exchanged every four or five days until the secretion diminishes. The injections may be started, unless another contraindication exists, in the presence of an open ulcer provided there are no signs of lymphangitis or periphlebitis. The decision when to start treatment requires experience and a few visits to some large teaching clinic are recommended. For obliterative injections sodium morrhuate and potassium oleate have proved satisfactory, their only drawback is the occasional development of hypersensitivity to the drug resulting in urticaria, edema and sometimes a serious anaphylactoid reaction.

ASYMPTOMATIC UNDULANT FEVER

To the Editor—In routine blood tests of the resident population a number of laboratory reports received indicate undulant fever in dilutions of from 1:100 to 1:1,000. All these patients have varying stages of pulmonary tuberculosis but are symptomless so far as can be determined for undulant fever. Will you please advise me regarding the significance of the test in this connection whether the presence of these patients in a group would make it inadvisable to retain them and what treatment if any should be employed?

ROBERT M. DEMING, M.D., Glencliff, N. H.

ANSWER—Subclinical or asymptomatic infections frequently occur following ingestion of raw milk containing *Brucella* organisms or after direct contact with infected animals. C. V. Carpenter, Ruth Boak and O. D. Chapman (*J. Immunol.* 17:65 [Jul. 1929]) have submitted convincing evidence that anti-abortus agglutinins develop only when there has been actual invasion of tissues by living *Brucella* organisms. There is no evidence that agglutinins are absorbed passively in the intestine from pasteurized milk containing killed organisms. Unless the history reveals evidence of symptoms compatible with a diagnosis of undulant fever it is quite likely that these patients belong in the asymptomatic or subclinical group. There is no evidence that the disease is contagious from man to man. Several investigators have reported the successful use of *Brucella melitensis* (abortus) vaccine therapy in the symptomatic form or the disease.

RECURRENT ERYSIPELAS OF LEG

To the Editor—A married woman aged 44 had an attack of erysipelas in her right leg eight years ago. Two or three years later she had a second attack. These attacks have gradually come closer and closer together until within the last year she has had seven attacks. A roentgenogram of the leg shows the bone perfectly normal. All her teeth have been roentgenographed, her tonsils are innocent, the sinuses are clear, pelvic examination is negative and I am unable to find any focus of infection. The urine is normal. Menstruation is regular but comes every twenty-four days. Have you any suggestions as to the prevention of future attacks? I have thought of making a culture from a blister should one ever develop with the idea of making a vaccine but so far in none of the attacks have blisters been present and I did not feel that a culture made from the skin itself would be reliable. Treatment of each attack has been by the use of epsom salt compresses and such symptomatic treatment as was indicated.

WINGATE M. JOHNSON, M.D., Winston-Salem, N. C.

ANSWER—Recurrent erysipelas of the leg has most frequently as the nidus of infection an *Epidermophyton* infection about the toes, and in order to prevent recurrence it is necessary for the usual treatment to be applied for such infections. Vaccines are of little use, but immunization by means of erysipelas toxin has proved of value.

CHRONIC EDEMA OF ANKLES

To the Editor—About two years ago Miss D. who does considerable tap dancing noticed that after strenuous dancing her left ankle would swell with pitting edema. This would disappear after eight hours rest in bed. The patient now 18 is healthy, has never had any serious illness and so far as I can see shows no evidence of organic disease. About a year ago she entered the clinic of a local orthopedic hospital for treatment and diagnosis. Entire physical including pelvic examination was negative as were roentgenograms of her left leg. After about eight months attendance at the clinic she became convinced that the line of treatment employed—heating and massage especially—was not productive of results and I was consulted. When first seen about two weeks ago the ankle was slightly swollen but not tender and the patient did not walk with any demonstrative limp. My suggestion to her was that perhaps as long as two years ago she had a thrombophlebitis of the deep vessels of the leg and the proper line of treatment was to get off the foot and stay off. This she agreed to do and I fixed up a wire tent with an electric bulb within to supply heat and I have kept this on at all times. She has been wearing woolen ski socks in conjunction with the external heat. One week ago while I was on a trip she reports that the ankle ballooned up and has not been free from swelling since. Today there is pitting edema over the dorsum of the foot but none above the ankle, this of course being after she has been off the foot for two weeks. My impression of this case is that it is an old thrombophlebitis of the deep vessels. If so is not two years a long time for her to have symptoms? How could this be treated except by rest in bed and external heat? Are there any other possibilities that suggest them selves to you? Any help you may give me will be very acceptable. Please omit name.

M D New Jersey

ANSWER—Unilateral pitting edema of the lower extremity that is relieved by horizontal or elevated position suggests deep venous obstruction. Should there be a cyanotic hue and the appearance of collaterals when the edema is not present, the diagnosis is more certain. The gradual painless onset however in the absence of any history of operation or infectious disease, may speak for lymphatic obstruction due to a chronic obliterative lymphangitis. Sometimes both venous and lymphatic factors are present. If the temperature, white count and sedimentation rate are normal the presence of active infection may be excluded. The principles of treatment are first to get rid of the edema and second to prevent the fluid from reforming, as long continued edema leads to a fibrosis and hypertrophy of connective tissue. Elevation of the limb to an angle of approximately 30 degrees over night helps to get rid of the fluid should some remain, from 4 to 6 Gm. of ammonium chloride, followed on the third day by 1 cc. of salyrgan, readily mobilizes the residual edema, provided it still pits and there are no irreversible changes in the tissues. To keep the fluid out of the limb so deprived of edema water is restricted to 1,000 cc. daily and no additional table salt is allowed. Five grams of potassium chloride may be prescribed and used instead of table salt. An elastic hose of the "Lastex" type is ordered from toes to the mid thigh or even to the groin should the swelling extend to that level. Exercise and walking are not prohibited as the contraction of muscles facilitates venous and lymphatic return, but standing in one position or even sitting in one position without elevating the limb tends to increase edema. The prognosis as to cosmetic results is quite guarded. If the obstruction is venous the circulation is apt to improve but with the diminution of the edema collateral veins may become visible. If the obstruction is lymphatic the edema may gradually increase in spite of all conservative treatment. In such cases radical surgical procedures that aim to drain lymphatic retention into nonaffected areas are justifiable.

OFFENSIVE DISCHARGE IN FEMALE

To the Editor—I have a patient aged 37 married who has one child aged 13 and has had two abortions since the birth of the child. Two years ago she had an ectopic pregnancy and operation revealed the left tube ruptured. The left ovary and tube were removed supravaginal hysterectomy was done on account of small fibroids in the fundus of the uterus and about 1 inch of the cervix was left. It was cauterized because of some erosion. The health of the patient has been good since the operation but she has a disagreeable vaginal discharge which has a very offensive odor while examination shows the remaining portion of the cervix in apparently healthy condition as well as the vaginal membranes. Every kind of douche has been used. I think in an attempt to destroy the odor all with little or no results. The patient menstruates regularly on a twenty eight day cycle with a small amount of flow for three or four days. There seems to be no definite time at which the discharge and odor are most aggravating. Treatments of the cervix with silver nitrate and antiseptics help a little as do daily douching with soda or copper sulfate. Will you please suggest further treatment and the possible cause of this odor? The patient has never had any venereal disease. If published please omit name.

M D Indiana

ANSWER—A bacteriologic study of the discharge should be made, including examination of fresh material for trichomonads.

If infection with a specific organism is not evident, the persistent discharge is probably ascribable to a cervical pocket that does not drain. A search for pockets can be made in the office without causing the patient undue discomfort. The cervix is grasped with volsellum forceps and the finest Hegar dilator is used as a searcher within the cervical canal.

In the event that there is neither evidence of a specific infection nor pocketing interfering with drainage, vaginal removal of the cervical stump is the procedure of choice.

DETACHMENT OF RETINA

To the Editor—Will you please give me information regarding prognosis and treatment of detachment of retina. Kindly omit name.

M D Alabama

ANSWER—Up to six years ago the visual prognosis in detachment of the retina was uniformly bad there being practically 100 per cent total loss of vision. But since the advent of surgical intervention as advocated by Gonnin the outlook has changed entirely. The prognosis for ultimate vision varies according to the length of time the detachment has existed the cause of the detachment, and the portion of the retina affected. Under favorable conditions, vision has been restored in as high as 70 per cent of the cases. But considering all cases except those that from the outset look hopeless, the number of recoveries may be estimated conservatively at around 40 per cent.

Except in the detachments of pregnancy, the treatment is entirely surgical. The main methods are (1) the Gonnin method of thermocautery through a scleral puncture (now practically abandoned), (2) the Guist method of chemical cautery through a scleral puncture (now reserved for only certain unusual cases), (3) the Safar or Walker method of diathermy coagulation by individual platinum pins inserted into the sclera, (4) the Weve method of diathermy coagulation by repeated introductions through the sclera of a single needle, and (5) the Larsen (modified by Coppex) method of superficial coagulation of the sclera by diathermy. All the methods aim at the closure of the retinal hole that is supposed to exist in every case and at the production of inflammatory areas in the choroid to which the retina becomes adherent, thus holding it in place. In reality our knowledge of the modus operandi of the surgical treatment of retinal detachment is still in its infancy.

ASYMPTOMATIC NEUROSYPHILIS

To the Editor—Please advise me in the following case. A man aged 40 was infected with syphilis in 1930. In 1932 he had his first course of eleven treatments each of a bismuth compound and neosarsphenamine. In 1934 he had two more full courses of a bismuth compound and neosarsphenamine. The blood Wassermann reaction at that time was 3 plus. He has had one more full course the fourth this year of a bismuth compound and tryparsamide. The blood Wassermann reaction is now 2 plus. To my amazement a test of the cerebrospinal fluid revealed a Wassermann reaction 2 plus Kahn reaction 4 plus globulin 4 plus and colloidal gold and colloidal mastic both weakly positive. The patient is symptomatically free and apparently in perfect health. Should he have further treatments of tryparsamide or a course of fever treatments or should I be content with the occasional course of the bismuth compound? Please omit name.

M D Ontario

ANSWER—This man appears to have an asymptomatic neurosyphilis. Several additional courses of tryparsamide with proper visual control alternating with a preparation of bismuth or mercury, should be given before administering fever therapy. If the spinal fluid continues positive, the latter procedure may be considered.

Council on Medical Education and Hospitals

INTERNSHIPS FOR GRADUATES OF FOREIGN MEDICAL SCHOOLS

Because many graduates of European universities and medical schools are applying for internships in this country, the Council on Medical Education and Hospitals at a recent meeting voted 'that when suitable graduates of class A schools of the United States and Canada are not available, hospitals approved for intern training may accept graduates of European schools who have passed parts I and II of the examinations of the National Board of Medical Examiners'.

Book Notices

Medical Uses of Radium. Summary of Reports from Research Centres for 1934. Medical Research Council Special Report Series No 991. Paper Price 1s 1p 45 with 7 illustrations. London His Majesty's Stationery Office 1935.

This is the thirteenth report of the Medical Research Council describing the research done with radium and radon distributed by the Medical Research Council to selected centers in Great Britain and Ireland. The original stock of radium entrusted to the council by the British government and lent by the council to various centers is supplemented by further quantities provided by the British Empire Cancer Campaign and by the National Radium Commission. The research, which has been continued for several years at the Strangeways Laboratory, Cambridge tends to show that biologic effects produced by radiation can be repeated over and over again with a measure of accuracy not always attained in purely physical fields, provided the most rigorous attempt is made to limit the number of variables operating at one and the same time. They find that to get a well recognized effect there is an optimum intensity at which the release of energy may occur. It has long been known that tissues react differently according to the time intervals over which the physical doses are applied, according to the type of radiation and according to the dose that is given but this apparently new observation is one that must sooner or later be taken into account in clinical conditions.

Dr Mottram has investigated the problem of artificially varying the degree of radiosensitivity of tissues. He has determined that those agents which are active in one direction or the other in animal cells produce corresponding effects in vegetable cells.

Investigation in the Bland Sutton Institute of Pathology at the Middlesex Hospital shows that when a portion of tissue is removed by the method of electrocoagulation good sections can be prepared from it for microscopic studies and there is the clinical assurance against dissemination.

Dr W V Mayneord of the Cancer Hospital reports further experimental work on the applicability of the roentgen to gamma ray therapy. The value previously found (of approximately 83 roentgens per milligram hour 1 cm from a point source filtered with 0.5 mm of platinum) has been confirmed by Dr Mayneord as well as by certain other observers. Further investigation on the design of air-wall ionization chambers for such measurements has been performed.

Crabtree and Cramer have shown, using animal tumors and the tissues of rats that the radiosensitivity of cells is greatly altered by treatments known to be specially effective in having an action on cellular respiration. Their results suggest that radiation may have a special action on the respiratory system which appears to be especially sensitive in its nonfunctioning oxidized phase. The results of the investigations by these authors suggest that the varying sensitivity of tumors to radiation is probably not related to mitotic activity but rather to the metabolic and perhaps the respiratory activity of the cells.

The report includes references to the treatment of mammary cancer in various institutions. The Aberdeen Royal Infirmary reports microscopic examination of thirteen breasts removed following radium treatment. In the Birmingham General Hospital the standard method of treatment of mammary cancer has been complete interstitial irradiation as outlined by Keynes. Two or three months later, external radiation is applied. In the Marie Curie Hospital the operable lesions have been treated by radical operation and radium has been restricted to the inoperable group. In the Middlesex Hospital radical operation is performed for operable lesions by some surgeons and radium tubes are inserted as a prophylactic measure in the intercostal spaces. Some lesions are treated by interstitial radiation. An increasing number of patients are receiving preoperative roentgen treatment. In the Royal Free Hospital early lesions are treated by radical surgery in some cases combined with radium therapy. Mr Geoffrey Keynes of St Bartholomew's Hospital reports that during the last three years the procedure in the treatment of cancer of the breast has been varied by performing excision of the tumor with diathermy when it is small or

a local removal of the breast when the growth is larger. The routine treatment with radium is then carried out from two to three weeks later. It is believed that the local excision reduces the incidence of local recurrence in the breast. The Surgical Unit of the St Bartholomew's Hospital after studying the comparative results of treatment of cancer of the breast by surgical operation and by interstitial radiation, concludes that the five year survival rate of the two methods of treatment is not materially different, being in each case 40 per cent. It became evident that, if improvement was to be reached, a new line of approach should be tried. Consequently it was decided that the next attempt should be to combine interstitial radium with surgery. It is intended to study a series of fifty cases treated by this method before reaching any conclusion.

Nine hundred and sixty cases of carcinoma of the cervix have been treated in the Marie Curie Hospital during the first ten years of its existence. Recently there has been a moderate increase in the number of patients applying for treatment at an early stage. The Coutard technic of roentgen therapy is utilized and except in very advanced cases is combined with radium. Ninety-three cases of carcinoma of the corpus uteri have been treated by radium in the Marie Curie Hospital, representing only 40 per cent of the total group. When possible, hysterectomy has been performed. Eight hundred and thirty-three cases of nonmalignant uterine hemorrhage have been treated at the Marie Curie Hospital. Eighty-seven cases of myoma of the uterus were treated with radium. In four cases, hysterectomy was subsequently performed.

In August 1932 the King Edward's Hospital fund for London, acting with the Radium Commission put at the service of three London hospitals—the Cancer Hospital, University College Hospital and Middlesex Hospital—1 Gm radium units, that their utility in the treatment of malignant disease might be investigated. The report from the Middlesex Hospital states that the telerradium unit has continued to prove its usefulness to the radium department and has been in use both day and night. One hundred and nineteen patients have been treated by this means during the year. The report states that it is a method of therapy which is more convenient and associated with less danger to the staff than is the case when large molded applicators are used. From the University College Hospital it appears that during the first two years of its use 109 patients were treated with the 1 Gm unit. The best results have been obtained with lesions that are not too deeply seated and when so located as to permit crossfiring from various directions. The solution of this difficulty obviously lies in the direction of treating at a greater distance, which in turn requires a larger quantity of radium.

Body Water. The Exchange of Fluids in Man. By John P. Peters M.D. Professor of Internal Medicine Yale University School of Medicine. Cloth Price \$4. Pp 405 with 5 illustrations. Springfield Illinois and Baltimore Charles C Thomas 1935.

From time to time it is of value to review important investigations and relevant studies to see how coherent they are in relation to an accepted hypothesis, to find where they disagree and to devise new experimental approaches for the solution of the problem. The author of this monograph is well qualified to examine such an important subject in this manner. The book, however, is more than a review of the movement of fluid and electrolytes and the nature of restraints the vital membranes of the body impose on them. It is a judicious and scholarly attempt to construct a background for a more rational analysis of the functional pathology of various chemical and pathologic disturbances. The disturbances related to renal injury receive major consideration. The author develops his thesis from fundamental discussions of chemical forces that control exchanges of fluid and solutes the nature and movements of interstitial fluid and lymph, exchanges between blood and interstitial fluids, blood cells and serum cells and fluids and alimentary exchanges. He then considers the dynamic physiology of the kidney and the general nature of renal activity as a basis for interpretation of the phenomena seen in renal disease. The desirability of distinguishing between changes secondary to renal damage and those resulting from such involvement are clearly indicated. While the book is not intended as an unprejudiced review of the subject, it is presented in such a scholarly and convincing manner that it

unconsciously serves that purpose. More than 800 critically selected references are correlated and cited. The book is highly recommended as an important contribution to the subject and one which clinicians can profitably read with the physiologist and the biochemist.

Haarkrankheiten und kosmetische Hautleiden mit besonderer Berücksichtigung der Therapie. Von Prof. Dr. R. O. Stein, Vorstand der Abteilung für Haut und Geschlechtskrankheiten am Mariahilfer Ambulatorium und Spital in Wien. Pp. 1260. Price 12.60 marks. Pp 218 with 6 illustrations. Vienna Julius Springer 1935.

Stein has presented in a readable style the subject of diseases of the hair and cosmetic ailments of the skin. The work is divided into two parts. Part A deals with diseases of the hair, which are discussed under the topics of the hair covering of man, excessive hair growth defects in hair covering and the hair shaft, mechanical disturbances of the hair shaft the saprophytes that involve the hair shaft, and hair loss. The latter is divided into two separate topics conditions that affect the mature hair and conditions affecting the hair papillae. Part B deals with the cosmetic diseases of the skin, which are discussed under the headings of nevi, tumors, scars and keloids, hyperpigmentation and depigmentation, anomalies in secretion of the sebaceous glands, anomalies in secretion of the sweat glands, angioneurosis, hyperkeratosis, and senile changes and correction of wrinkling of the face. The book treats the subject in a scientific manner, with free citations of the names of workers who have contributed pertinent articles bearing on the subjects discussed. Etiology, pathogenesis and various methods of treatment that can be employed are discussed. While some of the therapeutic agents are of a type not available in this country, the majority of the preparations recommended can be compounded here. The methods of treatment on the whole are conservative and conform in the main with the accepted methods used and recommended by American dermatologists. Stein gives a detailed discussion of the method of employment of a filtered technic for the roentgen treatment of hypertrichosis. Most American dermatologists do not feel that epilation by x-rays for hypertrichosis has a place in treatment because of the dangerous sequelae resulting from its use. The book should serve as a useful addition in the library of medical men interested in this phase of diseases of the skin and its appendages.

Practical Orthodontia. By Martin Dewey DDS MD FACD. Revised by George M. Anderson DDS Professor of Orthodontia Baltimore College of Dental Surgery Dental School University of Maryland and others. Fifth edition. Cloth Price \$8.50. Pp 514 with 556 illustrations. St. Louis C. V. Mosby Company 1935.

This is a new edition of the orthodontic textbook of the late Martin Dewey, arranged by George M. Anderson. Important additions have been furnished by the chapters written by the ten contributors. Dr. Anderson has attained the purpose set forth in the preface. 'To include in one volume authoritative material which will aid the student of dentistry, the practitioner of dentistry, and the student of orthodontia to understand the problems which confront those who choose to practice orthodontics.' Both students and practitioners of dentistry as well as specialists in the field of orthodontics will find much of value. Any author of such a work is confronted with no inconsiderable problem. The many contributions that have been made in this specialty, particularly in the last twenty years preclude the possibility of more than a statement of principle in one volume. While a statement of principle is of material value and importance to the student of dentistry, the requirement of the practitioner in this specialty demands a comprehensive treatment of both fundamental principles and the details of technic. From this standpoint the volume occupies an intermediate position. A simple presentation of principles such as is admirably accomplished in the chapter by Rudolf Kronfeld, on tissue changes incident to orthodontic tooth movement, would permit a material reduction in the size of the volume, while a comprehensive treatment of the subject matter would necessitate extensive expansion.

Dr. Bernhard Weinberger has contributed an excellent chapter on the historical background of modern orthodontia. Chapter 5 on the etiology of malocclusion, reveals by its attention to detail and its avoidance of principle a serious void in the knowledge of orthodontia. It is probable that time will have to contribute through careful and intelligent investigation more satisfactory

data before it will be possible to rationalize the principles that underlie the production of malocclusion. As these principles become clearer the detailed recitation of particular active causes will assume a more rational position. There is an extensive treatment of diagnosis including the specialized techniques that have recently come into prominence. Of particular note in this connection are gnathostatics and photostatics in chapter 8, radiographic profiles by Sidney Riesner in chapter 7 and measurement of dental-facial changes in relation to the cranium by B. Holth Broadbent in chapter 9.

Attention is appropriately given to an important phase of orthodontic science included in the prevention and correction of malocclusion by other than mechanical means. In this respect the chapter on myofunctional treatment of malocclusion, by Alfred Paul Rogers is of importance. A detailed exposition of band technique is included in the contribution of Earl W. Swinehart on orthodontic bands. Mechanical appliances in most common use are presented in chapters 17, 18, 19 and 20.

The matter of retention is given a short chapter which is satisfactory from the standpoint neither of principle nor of detail of practice. The final two chapters deal with correlation between orthodontics and two closely allied specialties, oral surgery and that of the nose and throat. The former written by Edward A. Kitlowski furnishes a discussion of the principal deformities interesting to both specialties. The latter is a brief recognition of the close relationship that exists between the oral and the nasal cavity and the nasal sinuses.

A Basis for the Theory of Medicine. By A. D. Speransky, Director of the Department of Patho-Physiology of the All Union Institute of Experimental Medicine. Translated and edited by C. P. Dutt, B.A. With the collaboration of A. A. Subkov, Senior Research Worker of the Timirязev Biological Institute. Cloth. Pp. 442 with 19 illustrations. Moscow: Izdat. Co. Operativ Publishing Society, 1935.

This monograph with a rather ambitious title will impress the reader with the way in which the Pavlov school has dominated Soviet medical science. The text deals almost exclusively with neurophysiology and at times a philosophic attempt to explain diverse pathologic and clinical observations on that basis. The book lacks clarity and organization and much interesting information is submerged as a result of it. The author discusses the nervous mechanism of complex convulsive states, the role of the cerebrospinal fluid in the genesis of some forms of encephalitis, its circulation, the role of the nervous system in the pathogenesis of certain infectious diseases and dystrophic processes within the nervous system. Original experiments are cited throughout the text. While many thoughts expressed in the book are provocative it lacks unity. The main criticism of this monograph is its unjustified generalizations. The author has strayed too far from his material. He has presented a great deal of theory with meager basis for it. Before pulling down the old edifice, one must have more than architectural aspirations for the new one.

Practical Clinical Psychiatry for Students and Practitioners. By Edward A. Strecker, A.M., Sc.D., M.D., Professor of Psychiatry and Chairman of the Department of Psychiatry, School of Medicine, University of Pennsylvania, and Franklin G. Fbaugh, A.B., M.D., Professor of Psychiatry, University of Colorado Medical School. Fourth edition. Fabrikoid. Price \$5. Pp. 705 with 60 illustrations. Philadelphia: I. Blakiston's Son & Co., Inc., 1935.

The new edition, the fourth in ten years of this popular textbook is dedicated to Dr. Adolf Meyer. His psychobiologic point of view and teachings richly pervade the whole book. There are 125 more pages than in the previous edition. Rearrangement of certain material and rewriting of other parts have resulted in distinct improvement. There is a new first chapter on psychobiologic conceptions of mental disorders. The autobiographic or planned personality study of himself by the student is favored for his better subsequent understanding of psychiatric patients. The new American classification of mental diseases in about fifty groups is included for reference although the author's original list of seven fundamental types is retained. Methods of examination have been amplified. A discussion of the Kettering hyperthermia is added to the section on therapy of neurosyphilis. There are many new illustrations. The new final chapter is by Dr. Leo Kanner on psychopathologic problems of childhood. As an introduction to modern psychiatry this volume is the superlative of good.

Handbuch der experimentellen Pharmakologie. Herausgegeben von A. Heffter. Fortgeführt von W. Heubner, Professor der Pharmakologie an der Universität Berlin. Band III, Teil 4. Seltene Erdmetalle, Molybdän und Wolfram. Bearbeitet von B. Behrens u. a. Paper. Price 48 marks. Pp. 2189-2730 with 14 illustrations. Berlin: Julius Springer, 1935.

This volume of the Handbook on Experimental Pharmacology is devoted most especially to an exhaustive exposition of the pharmacology of bismuth (over 500 pages), a discussion of what is known about molybdenum and tungsten, and a chapter on the rarer earth metals. In pharmacologic action the latter resemble one another and aluminum as well and to a certain extent thorium. Especially marked is the resemblance between neodymium and praseodymium while there are, on the other hand, rather marked differences in case of yttrium, lanthanum and scandium. It has been shown that cerium cannot replace calcium or magnesium. The use of cerium oxalate as an anti-emetic seems to have a certain amount of experimental justification. Colloidal molybdenum seems to have chemotherapeutic possibilities in various infections including tuberculosis. In the section on bismuth August W. Forst discusses interestingly the history of the therapeutic use of bismuth compounds and points out that "magisterium bismuthi" (bismuth subnitrate) after several ups and downs in therapeutic favor has been deleted as superfluous, from the British pharmacopoeia of 1933. In view of the fact that bismuth has been tried for almost everything, it is not strange that it was recommended as early as 1788 by Bassiano Carminati as a remedy for syphilis, a use around which the chief interest in bismuth centers today. While bismuth salts themselves have no spirocheticidal action in vitro such power is developed by incubation with fresh tissue extract. This effect is found to reside in a thermolabile, nondialyzable bismuth-protein combination for which the term "bismoxyl" has been proposed and it is believed that in this form bismuth circulates and exerts its therapeutic action. For the tissue extract 'principle' responsible for the production of bismoxyl the term "bismogen" has been suggested. In the affected tissues bismoxyl is present in such minute traces that it must act as a catalyzing influence in accelerating the natural parasitolytic defensive principles. In contrast to the arsenicals bismuth action on the syphilis spirochetes is exceedingly slow in asserting itself but protection derived from it is much more durable. Future improvements in syphilis therapy with bismuth may depend on the development of compounds with the highest possible bismuth content and lowest possible toxicity.

Modern Treatment in General Practice. Volume II. Edited by Cecil P. C. Wakeley, D.Sc., F.R.C.S., F.R.S.E., Fellow of King's College, London. Cloth. Price \$4. Pp. 382 with illustrations. Baltimore: William Wood and Company, 1935.

This is a collection of reprints of articles that appeared weekly in the *Medical Press and Circular*, the subjects ranging in a more or less haphazard manner from the therapy of peptic ulcer, constipation, asthma and thyrotoxicosis to the treatment of facial injuries, athletic injuries, and several varieties of fractures. Each article is prepared by an eminent specialist student of the subject, with illustrations wherever they may be of advantage. One senses the voice of experience emanating from the pages of this book, which can be unreservedly recommended most especially to the general practitioner.

Agents of Disease and Host Resistance Including the Principles of Immunology, Bacteriology, Mycology, Protozoology, Parasitology and Virus Diseases. By Frédéric P. Gay. In association with nineteen others. Cloth. Price \$10. Pp. 1581 with illustrations. Springfield, Illinois and Baltimore: Charles C. Thomas, 1935.

This is a comprehensive treatise on the agents of disease and resistance of the host. It embraces the principles of bacteriology, mycology, protozoology, parasitology and virus diseases. It is monographic in scope and completeness, yet in its uniformity and point of view it is much like a comprehensive textbook. This has been achieved by careful editing and organization of material from experienced collaborators who for the most part have been associated with the author in the same department. The text deals essentially with the principles of the respective subjects and purposely omits technical methods. While this type of organization will distinctly limit its immediate usefulness for the laboratory technician it will more than compensate for the fundamental knowledge it will impart. The book will probably find its greatest use as a reference work.

but is a valuable addition to any physician's library. It is adequately illustrated and notably free from errors. Each subject is supplemented by a critically selected and unusually complete bibliography. The book is highly recommended as an important contribution to any medical library.

Die Praxis der Sterilisierungsoperationen Von Prof. Dr. med. A. H. Bauer, Direktor der chirurg. Universitätsklinik Breslau und Prof. Dr. med. E. von Mikulicz-Radecki, Direktor der Universitäts-Frauenklinik Königsberg. 1. Pp. Paper. Price 15.40 marks. Pp. 176 with 91 illustrations. Leipzig: Johann Ambrosius Barth, 1936.

The Nazi government in Germany has caused medical men to review rather carefully the so-called medical indications for the operation of sterilization. The first section of the monograph by Bauer and Mikulicz-Radecki is a discussion of the indications for this operation which is now required in Germany. It also gives the legal forms that are used in cases in which sterilization is employed. The second section of the book describes the various operations that may be used for the sterilization of men. The third section deals with the types of operations suitable for the sterilization of women. The operative procedures are shown in the illustrations. Eight pages of bibliography and the index complete the volume. Those who are interested in the study of medical sterilization will find this an interesting contribution to the subject.

The Spleen and Resistance. By David Peck, M.D., Associate Pathologist and Bacteriologist, Montefiore Hospital, and Jessie Marmorston, M.D., Associate in Pathology, Cornell University Medical College. With a foreword by David Marine, M.D. Cloth. Price \$2. Pp. 170. Baltimore: Williams & Wilkins Company, 1935.

One of the factors that determine the infectibility as well as the sequelae of infections in the human body has been constantly associated with the spleen and the reticulo-endothelial system. A fair amount of medical literature has been devoted to this interesting but elusive subject. The authors of this monograph have not only critically evaluated that literature but cite their own contributions in detail which definitely add to our knowledge. Human as well as animal material has been utilized for study. The introductory chapter on anatomic considerations of the spleen is concise but adequate. Then follows a detailed consideration of the pathologic changes in the spleen in various types of infections of bacterial, virus, parasite and fungus origin. The functions of the spleen as an organ of macrophage tissue and antibody formation are next discussed and this material is correlated with changes after splenectomy. Each phase of the subject and pertinent literature are well summarized and judiciously interpreted. This concise but comprehensive presentation should be of interest to the clinician as well as to the pathologist and the bacteriologist.

Clinical and Pathological Applications of Spectrum Analysis with Notes on Spectrography in Chemistry and Mineralogy and Tables for Qualitative Analysis. By Dr. Walther Gerlach and Dr. Werner Gerlach. Being the authorized translation of Part II of *Die chemische Emissionsspektalanalyse*. Translated by Joyce Hilger Wyman. Cloth. Price 15s. Pp. 143 with 50 illustrations. London: Adam Hilger Ltd, 1934.

This volume is the authorized translation of part II of *Die chemische Emissionsspektalanalyse* by Dr. Walther Gerlach and Dr. Werner Gerlach. Adam Hilger Limited, the spectrograph manufacturer, of London, is the publisher and distributor of this translation. If one has spectrographic equipment, expensive though it may be, much of interest and of value may be accomplished in the various fields of study, among which may be listed toxicology of various kinds. Special methods are given for the qualitative and quantitative analysis of organs secreted and excreted. The use of the spectrograph as applied to electropathology and pneumoconiosis is also described. Other subjects of a general nature are treated. If one does not have spectrographic equipment the book is without practical value.

Manuel de coprologie clinique. Par R. Goltzon. Preface de J. Ch. Loun. Third edition. Paper. Price 28 francs. Pp. 274 with 45 illustrations. Paris: Masson & Cie, 1935.

This small manual well deserves its third edition. It is concise and well written. The subject is thoroughly covered and brought down to date. The chapter dealing with the physiology of the gastro-intestinal tract is especially to be commended. All phases of the subject are given in detail including the chemical, bacteriologic and allergic. The parasitology is exceptionally well given, with numerous well-chosen illustrations.

Popoff's Quantitative Analysis: The Theory and Practice of Modern Analytical Chemistry with Problems and Explanations of Calculations. Revised by Murray J. Rice, Ph.D., Professor of Chemistry, New York State College of Ceramics at Alfred University, and Warren P. Cortelyou, B.S., Assistant Professor of Chemistry, New York State College of Ceramics at Alfred University. Third edition. Cloth. Price \$4. Pp. 555 with 76 illustrations. Philadelphia: P. Blaisdell's Son & Co., Inc., 1935.

This volume is intended to be used as a textbook and laboratory manual in beginning inorganic quantitative analysis. For this purpose it should prove useful. The treatment of theoretical subjects is good. Micromethods and methods of analysis for organic substances are not included.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Workmen's Compensation Acts—Scarlet Fever Not a Compensable Injury—The plaintiff, an employee in the cafeteria operated by the defendant hospital, contracted scarlet fever allegedly from a student nurse with whom she came in contact in the course of her employment. In a proceeding under the workmen's compensation act of Michigan, the department of labor and industry awarded compensation to the plaintiff and the defendants appealed to the Supreme Court of Michigan.

Although the plaintiff might possibly have contracted the disease outside the hospital, the court said, the evidence constituted some basis for the finding that the plaintiff contracted the disease in the hospital in the course of her employment. But continued the court, the purpose of the workmen's compensation act is to give compensation for industrial accidents. It protects employees against all accidental injuries arising out of and in the course of employment, whether caused by the negligence of the employer or not, but not against a contagious disease contracted from a fellow employee. The court expressed itself as impressed with the reasoning of Judge Cardozo in *Connelly v. Hunt Furniture Co.*, 240 N. Y. 83, 147 N. E. 366, as follows:

Germs may indeed be inhaled through the nose or mouth or absorbed into the system through normal channels of entry. In such cases their inroads will seldom, if ever, be assignable to a determinate or single act identified in space or time. [Citations omitted.] For this as well as for the reason that the act of absorption is incidental to a bodily process both natural and normal their action presents itself to the mind as a disease and not an accident. Our mental attitude is different when the channel of infection is abnormal or traumatic, a lesion or a cut. If these become dangerous or deadly by contact with infected matter we think and speak of what has happened as something catastrophic or extraordinary, a mishap or an accident, though very likely a disease also.

In the opinion of the court in the present case, the contraction of a contagious disease under the circumstances here presented did not constitute an industrial accident and did not come within the purview of the workmen's compensation act. The award was consequently set aside—*Basil v. Butterworth Hospital (Mich.)*, 262 N. Y. 281.

Roentgenograms—Ownership of Roentgenograms—The defendant company employed the plaintiff, a physician, to treat one of its employees who had sustained an injury to the lower part of the back involving the sacro-iliac joint. On the refusal of the company to pay for the services rendered, the plaintiff brought suit. A judgment was rendered in favor of the plaintiff and the defendant appealed to the Supreme Court of Michigan.

The defendant declined to pay the bill because the plaintiff refused to deliver to it certain roentgenograms taken during the course of treatment. The plaintiff was justified in thus refusing to surrender possession of the roentgenograms, said the Supreme Court. In the absence of agreement to the contrary, roentgenograms are the property of the physician who has made them incident to treating a patient, notwithstanding their cost is charged to the patient. Their retention by the physician constitutes an important part of his clinical record.

in the particular case, and in the aggregate roentgenograms may embody and preserve much of value incident to a physician's experience. They are as much a part of the history of the case as any other case record made by a physician. Roentgenograms differ little if at all from microscopic slides of tissue made in the course of diagnosing or treating a patient, and it would hardly be claimed that such slides were the property of the patient. Furthermore, continued the court in the event of a malpractice suit against the physician the roentgenograms that he has caused to be taken and preserved incident to treating the patient might often constitute the unimpeachable evidence which would fully justify the treatment of which the plaintiff complained. In reaching its conclusion the court relied on the cases of *Colless v E W Heller Co* (C C) 64 F 280 31 L R A 283, and *Pollard v Photographic Company*, 40 Ch Div 345, in which it was held that the negative of an ordinary photograph, in the absence of an agreement otherwise, belongs to the operating photographer although his use thereof may be restricted.

The judgment in favor of the physician was affirmed—*McGarry v J A Mercier Co (Mich)*, 262 N W 296

Workmen's Compensation Acts Physician's Right to Initiate Proceedings Before Industrial Accident Board—A workman injured in the course of his employment was treated in a hospital by the physician-plaintiff, on the written authorization of the workman's employer. The employer's insurance carrier paid the hospital bill, \$315. Later the workman was treated in another hospital by another physician, and for the services of both hospital and physician the insurance carrier paid \$185. The workman settled his claim against his employer for compensation, with the approval of the Montana industrial accident board. Thereafter, the physician who treated the workman immediately after the injury sent to the insurer a bill for services rendered. The insurer refused to pay and the physician initiated proceedings before the Montana industrial accident board to compel him to do so. The board dismissed the proceedings, and its action was affirmed by the district court, Glacier County. The physician thereupon appealed to the Supreme Court of Montana. The insurer contended (1) that, as the Montana workmen's compensation act limited an employer's liability for medical and hospital services to \$500, it had already discharged its obligation since it had paid that amount and (2) that the industrial accident board was without jurisdiction to hear the proceedings instituted by the physician.

The Supreme Court pointed out that this was not a proceeding before the industrial accident board by the injured workman, seeking an award on account of medical or hospital services. If it were said the court, the board would undoubtedly have jurisdiction. Here, however, the claimant is a physician who has rendered services to the injured workman, and neither the workman nor his employer is a party to the proceedings. The Montana workmen's compensation act does not specifically authorize the board to fix the fee charged by any person for any service in connection with the act as do some other state compensation acts but it authorizes the board only to determine disputes or controversies arising under the act. Even under statutes that authorize industrial accident boards to fix medical fees, said the court it is generally held that a physician may maintain an action at law to recover for services rendered an injured workman and that the courts have jurisdiction. Under such statutes it is generally held, too, that an industrial accident board or any similar agency is without jurisdiction to make an award to a physician who has rendered medical services at the request of an employer or insurance carrier. In the judgment of the Supreme Court the Montana industrial accident board in approving the settlement between the employer and his injured workman, had exhausted its jurisdiction before the present proceedings were initiated. The board therefore was without authority to entertain the physician's claim. The physician's remedy in this case, if he had any, the Supreme Court concluded was an appropriate action in court. In view of this fact the Supreme Court found it unnecessary to pass on the contention of the insurer that it had satisfied the liability of the employer and itself when it paid for medical and hospital services without reference to the present claim, the sum of \$500 the statutory limit.

The judgment of the court below, affirming the action of the industrial accident board dismissing the proceeding instituted by the physician, was affirmed—*Leist v United States Fidelity & Guaranty Co (Mont)*, 48 P (2d) 772

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to *THE JOURNAL* in continental United States and Canada for a period of three days. Periodicals are available from 1926 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Collapse Therapy for Tuberculosis and the Menstrual Physiology—Jameson says that a study of seventy-four cases of tuberculosis has shown that thoracoplasty results in definite changes in the menstrual function. The untoward results noted cannot always be attributed to an increase in the tuberculous lesion or to a further deterioration in the patient's health. It would seem that the usual explanation of a "toxemia of tuberculosis as the cause of abnormal menstruation in tuberculous women is inadequate and that the problem should be approached from the same angle and with the same broad point of view that obtains in the investigation of endocrine dystrophies in nontuberculous women.

Prophylaxis Against Puerperal Infections—Bernstein and Otten undertook to culture the organisms commonly found in puerperal infection, test their effect on laboratory animals and by means of a vaccine made from the cultures endeavor to elevate the immunity of the pregnant woman to puerperal infection in general. The technique of preparing the vaccine in the experimental trials in mice and the results obtained by the use of the vaccine in fifty-one pregnant women are discussed. Active immunity was conferred to mice by means of repeated injections of vaccine. The safety and absence of reactions to the vaccine were first demonstrated in a series of nonpregnant women of the childbearing period. From three to thirteen injections of the vaccine were given the fifty-one pregnant women without untoward reactions. Each patient was first given an intracutaneous injection of 0.05 cc of vaccine on the flexor surface of the forearm. Subsequent injections at weekly intervals were given intramuscularly in the deltoid region. The initial intramuscular injection was 0.1 cc. The dosage was gradually increased to 0.2 cc per injection. Abortion or mis-

carriage did not occur. Preexisting conditions in these cases, whether acute or chronic were not aggravated by vaccination. These fifty-one patients delivered with no fatalities. The puerperal morbidity was 59 per cent as compared to the combined morbidity of the nonvaccinated cases which was 19.01 per cent. There was one stillbirth, the mother being a preeclamptic patient with marked hypertension and a separated placenta. The authors feel that this type of vaccination of pregnant women should be included in the armamentarium of antepartum care.

Water Concentration of Blood During Pregnancy—Oberst and Flass studied the moisture content of plasma and cells in relation to variations in the plasma proteins and the cell hemoglobin in twenty pregnant women (ten primigravidas and ten multigravidas), ten parturient women, ten puerperal women and ten nonpregnant women who served as controls. The pregnant women were in the latter part of the third trimester of pregnancy. The obstetric patients were clinically free from disturbing disease conditions, while the nonpregnant group consisted of nurses and of patients with minor complaints who were in the gynecologic wards. All individuals were given an ordinary mixed diet and, except for the parturient and puerperal patients, were not confined to bed. The study disclosed that during the active childbearing function of women, the water concentrations of whole blood, plasma and cells follow the same general curve, which is the reverse of that noted for specific gravity of whole blood and plasma, cell volume, plasma proteins and hemoglobin content of whole blood. These observations confirm the conception of a blood dilution during pregnancy with prompt elimination of the excess water during parturition and the puerperium. There is evidence that the body attempts to compensate for this dilution by increasing the hemoglobin content of individual cells, which consequently show an increased specific gravity. The slight anemia of normally pregnant women recognized by clinical methods is only apparent and can be explained by physiologic dilution of the blood associated with an increased blood volume, and by the further dilution of finger-prick blood with the fluid from edematous subcutaneous tissues.

Changes in Bone Marrow in Agranulocytosis—From an analysis of their twenty-five typical cases of agranulocytosis of which they had adequate and properly prepared sections of bone marrow, it appears to Darling and his associates as Fitz-Hugh and Krumbhaar first suggested that in the rapidly fatal cases the bone marrow shows stem cell hyperplasia and myeloid anaknesis (maturation arrest) without notable changes in the red cell series and that as the survival of the patient becomes longer the stem cells gradually and somewhat irregularly give way to plasma cells and lymphocytes. It may be hypothesized that early in the disease there is a compensatory increase of the number of normally occurring stem cells (myeloblasts) in a vain effort to overcome the maturation arrest and that these stem cells disappear in the latter stages and a coincident increase of lymphocytes and plasma cells occurs.

Lesions in Cardiac Conduction System in Rheumatic Fever—Gross and Fried examined 110 human hearts to determine the nature and frequency of the lesions occurring in the

Tawara node and bundle of His in rheumatic fever. Sixty or these cases represent active rheumatic fever twenty-five cases inactive rheumatic fever and twenty-five cases nonrheumatic material. In active rheumatic fever there occurs a variety of inflammatory and vascular phenomena within the horizontal conduction system as well as in the surrounding tissue. Even when studied in few representative specimens from each bundle, the incidence of these lesions was approximately 66 per cent in the active material. It is probable that a study of more sections would have indicated a higher incidence. Very few of these lesions are of a specific or highly characteristic nature. The inactive rheumatic cases showed few pathologic changes. This is in keeping with the functional differences observed as between these two groups. There is a high incidence of inflammatory lesions in the collagenous extension of the septum fibrosum. The possible mechanisms concerned with the spread of the rheumatic infection to the bundle tissue is discussed.

Effects of Oxygen at Pressure of Three Atmospheres

—Behnke and his co-workers observed that oxygen at a pressure of three atmospheres (30 pound gage) can be breathed by healthy men for three hours without distressing symptoms. During the fourth hour a progressive contraction of the visual field with dilatation of the pupils and some impairment in central vision is the most constant criterion of oxygen toxicity. Circulatory changes indicative of peripheral vascular constriction are associated with the visual impairment and culminate during the fourth hour in an abrupt rise of systolic and diastolic blood pressure, increase in pulse rate and extreme pallor of the face. At this stage the subjects experience dizziness and a feeling of impending collapse. A condition of partial stupor is indicated by the facial expression and the slowed mental responses. Rapid and complete recovery attended by a feeling of alertness and stimulation takes place within an hour after air is substituted for oxygen.

Hereditary Occurrence of Enlarged Parietal Foramina

—The interest of Pepper and Pendergrass in enlarged parietal foramina was aroused by the presence of the anomaly in a patient in the medical ward of the Hospital of the University of Pennsylvania. The patient stated that other members of his family had the same anomaly. The authors were able to examine the patient's mother, his son, his sister and her four children. The patient's grandmother was dead, but the members of the family all were positive that they had frequently felt the "holes" in her head. The mother exhibited very large foramina, as did the son. These were easily found by palpation. The patient's sister had bilateral foramina which were small, were larger than normal. This sister has four children. The oldest, a boy, has foramina similar to his mother's, the second child, a son, has openings measuring 7 mm on the right and 3 mm on the left. Of the two younger girls the elder has bilateral foramina of top normal size, the younger of normal size. A search of the literature proves the authors' observations not unique, for they have found the report of one similar family. Also in the older literature there are a few hints in this direction. The most important report is that of Goldsmith in 1922. He points out that the inheritance does not seem to fall in line with any of the usual laws of inheritance. He believes that the openings are larger in the young and that at first it is a single opening, which is later divided by the ossification of a median bridge. He also believes that the defect may disappear as adult life is reached. Some support for these opinions is supplied by the authors' study of still another family exhibiting large foramina. One of their roentgenologic staff readily recognized the lesion in the films exhibited at a roentgenologic meeting. The defects shown in the skull films of a young girl were presented as possibly due to Hand-Schüller-Christian's disease, but to one who had once seen the picture of enlarged parietal foramina the diagnosis was obvious. In addition to the girl they have been able to examine her mother, her sister, two aunts and three cousins. Also the family insist the child's grandfather has the same "holes." One aunt has demonstrable foramina, but the other and the cousins are normal. The child's sister, only 7 months of age, has a large central defect. The child herself, 2 years of age, shows a large merged defect and also the not uncommon anomaly of the occipital bone called by some the "Inca bone." Apparently the defect is an erratic hereditary anomaly of ossification bearing no relation to any disease of the skeleton. There seems to be little support for the claims made by several writers that it results from increased intracranial pressure and is more apt to occur in those with small skulls. The anomaly is of only slight importance clinically, although the defects might be found and misinterpreted. The cranial defects with which enlarged parietal foramina might be confused are Hand-Schüller-Christian's disease, syphilis, secondary neoplasms, trephine openings, dysostosis (cleidocranial) of the cranial bones, meningocele and osteoporosis circumscripta. The roentgenologist will usually have the responsibility of making the differ-

ential diagnosis and will have the opportunity of identifying such instances of anomalous parietal foramina as he may encounter

Three Zones of Simple Pleural Effusions—Kaunitz describes the three zones of simple pleural effusions from below upward as follows 1 A radiopaque zone made up of a large volume of liquid displacing the lung upward and casting a dense curved roentgenographic shadow 2 A radiotranslucent zone consisting of a moderate volume of liquid interposed between the lung and chest wall and casting a moderately dense roentgenographic shadow 3 A radiotransparent zone representing a film of liquid too thin to cast a roentgenographic shadow

An Experimental Thrombopenic Purpura—Tocantins describes various changes in the blood of dogs with experimental thrombopenic purpura and analyzes the extent of the correlation between these changes and the external manifestations of the disease Morphologic variations in the platelets were regularly observed soon after a diminution in their level in the peripheral blood as well as preceding their return to normal after a period of thrombopenia The volume and rate of output of blood per unit time from a skin wound were increased and irregular during the acute phase of purpura and became markedly decreased in the first few days following recovery The highest correlations found were between the number of platelets and the degree of clot retraction and between the latter and the mean bleeding time The correlations were of such a degree as to indicate that factors other than those under analysis will be found to play important parts in the mechanism of normal and impaired hemostasis

Arteriosclerosis and Hypertension in Diabetes—Root and Sharkey say that there is an excess of arteriosclerosis in the coronaries, aorta and legs in diabetic patients as compared with nondiabetic subjects Among 175 diabetic deaths hypertension occurred in 54 per cent All the characteristic vascular lesions of diabetes (retinal hemorrhages, coronary occlusion, gangrene) occurred in cases of diabetes without hypertension as well as in cases with hypertension The incidence of these vascular complications was greater in the hypertensive group as if hypertension acted as an additional factor increasing greatly the tendency to such lesions The association of large vessel arteriosclerosis constantly whenever arteriosclerosis was present suggested that changes in the large arteries occurred first The etiology of arterial hypertension is divided under five heads (1) circulating substances including hormones (2) influence of the nervous system, (3) structural changes in the vascular system (4) infections and allergy and (5) constitutional factors There is no clear evidence in the authors' cases of unusual psychic or nervous make up on which to base the theory that hypertension occurred first and vascular disease followed Similarly the roles of infections and allergy lack support In diabetes infections of the kidneys are common and hypertension may follow such infections Somewhat more reasonable is the theory that the spotty lesions of arteriosclerosis represent the results of low grade and repeated bacterial invasion or degeneration due to bacterial toxins That the predisposition to diabetes is inherited as a mendelian recessive characteristic has received support from the studies of Pincus and White The authors' belief is that the premature and excessive development of vascular disease occurs predominantly in muscular

arteries under the greatest physical strain especially in obese patients, and is due to the metabolic changes of diabetes The coronary and leg arteries are chiefly involved, although changes in the arterioles also are found The necessity of insulin in the glycogen metabolism of muscle and especially for the completion of the lactic acid cycle must be of some significance in this connection, although the details are as yet undemonstrated The importance of the disordered lipid metabolism more easily demonstrated by present chemical and pathologic methods, is better understood Hypertension then is an important contributing factor in the clinical course of the disease because it imposes additional strain even when the patient has lost his obesity and accentuates greatly the vascular changes in coronary and leg arteries A further suggestion as to the metabolic factor in the arteriosclerosis of diabetes is the fact that with modern treatment with insulin and diet more normally balanced the frequency of arteriosclerosis in the legs of diabetic children is diminishing The objective in the future should be the earlier possible diagnosis of diabetes and its more aggressive treatment The final explanation will take full cognizance of the interrelationship of the endocrine glands of the parts played by pre-existent obesity, by infections, especially of the kidneys, and by inheritance

Extensive Pigmented Nevus—Netherton reports a case of extensive pigmented nevus associated with primary diffuse melanoblastosis of the meninges The correlation of these observations is difficult and depends on the ultimate solution of the origin of nevus and of the debated questions concerning the embryologic development of the meninges It is possible that the nevus and the changes in the meninges are related congenital malformations resulting from early developmental disturbances in the ectoderm and that such lesions may be considered as filling the gap that exists between extensive benign melanomas of the skin and primary melanoma of the meninges The diffuse and extensive involvement of the piaarachnoid interfered with absorption of the cerebrospinal fluid sufficiently to cause fatal hydrocephalus

Direct Microscopic Examination of Skin—Swartz and Cowart state that the treatment of scrapings from the skin with 5 per cent potassium hydroxide followed by washing with water and staining in lactophenol and cotton blue, makes possible the easy determination of the presence of fungi This method of preparing microscopic specimens for examination is simple in that it adds only two steps to the more common method using potassium hydroxide and is effective in that the fungi are definitely stained while the various confusing artefacts are eliminated from the picture This is particularly true of the mosaic growth that occurs commonly in preparations made with potassium hydroxide This material does not seem to be the result of treatment with potassium hydroxide since it can be found in scales treated with xylene or with chloral hydrate and acacia It was found to be soluble in either 95 per cent alcohol absolute alcohol and phenol It could not be stained with sudan III or scarlet red or blackened with osmic acid While fungi were readily stained with lactophenol and cotton blue mosaic material occurring in the same

preparation did not stain and was, in fact, entirely eliminated. In the presence of polarized light there was no evidence that the mosaic material was composed of crystalloid forms. Whatever the nature of the mosaic growth, the authors feel that they have presented sufficient proof that it is not a fungus. The staining of normal fungi in scales with lactophenol and cotton blue the failure to find partially degenerated forms in the same preparation in which both mosaic material and fungi occurred, and the failure to find morphologic connections between normal hyphae and these mosaic forms seem to disprove convincingly the theory that this material is a degenerate form of fungus.

Laryngeal Tuberculosis Requiring Tracheotomy—Myerson states that tracheotomy was performed in nine of 728 cases of laryngeal involvement in a total of 6,516 cases of pulmonary tuberculosis observed during a period of three years. Not every patient with pulmonary tuberculosis who becomes hoarse has specific involvement of the larynx. Several patients referred for treatment of tuberculosis because they were hoarse were found to have a nontuberculous lesion (cyst, vascular polyps, paralysis and carcinoma). Not every patient with pulmonary tuberculosis who is hoarse has tuberculosis of the larynx, although this should be suspected. Tracheotomy does not indicate a hopeless prognosis, nor does the presence of laryngeal involvement. Laryngeal involvement diminishes the prospect of recovery but does not doom the patient. Laryngeal obstruction is invariably caused by a productive lesion. The most frequent cause of laryngeal stenosis is a position of the vocal cord in the midline or almost in the midline which is caused by fixation of the crico arytenoid joint. The prognosis is always better in those cases in which the pulmonary lesions show a tendency to recovery and in which the sputum contains few or no tubercle bacilli. The same conditions influence the prospect in a case of tuberculous involvement of the tracheotomy wound. When the tracheal wound comes in contact with a large amount of bacillus-laden sputum, it usually becomes infected.

Ventricular Puncture—To facilitate the lifting of the dura from the bone in operations for acute suppurative petrositis, preliminary puncture of the lateral ventricle on the side opposite to the petrositis was suggested and tried by Kaplan. In most neurosurgical clinics the lateral ventricle is tapped during some stage of every suboccipital craniotomy. The reduced dural tension that follows is of great help in the exposure that Rosen and Kaplan use. To their knowledge, this preliminary step of ventricular puncture as part of the operation for suppuration of the petrous pyramid has not been mentioned or suggested heretofore. The ease with which the dura is stripped from the bone after emptying of the opposite lateral ventricle leads them to present the practical and theoretical advantages of the procedure. 1 Emptying of the lateral ventricle in the hands of an experienced neurosurgeon is attended with little risk. More than 100 consecutive ventriculographies have been performed at the Mount Sinai Hospital without any serious complication. The fact that the procedure was performed on patients in whom an intracranial neoplasm was suspected and in many instances found, indicates that the danger of simple drainage of the lateral ventricle is almost negligible. 2 In the cases in which petrositis is suspected, one cannot always be certain that an abscess of the brain has been

excluded. Drainage of spinal fluid, particularly if the abscess is situated in the cerebellum, may be followed by disastrous results. 3 Ventricular puncture may give a clue as to the presence of a cerebral abscess. Evidence of a dilated or displaced ventricle should make one suspicious of an expanding or obstructing cerebral lesion. 4 In doubtful cases in which exploration has failed to prove the presence of petrous suppuration subsequent ventriculography can be performed with ease through an already existing trephine opening.

Response of Essential Hypertension and Diabetes to X-Rays—Hutton and his co-workers have had under their supervision 177 cases of essential hypertension, twenty-one cases of hypertension and diabetes existing in the same patient and forty-six cases of diabetes mellitus without hypertension. Their use of x-rays in the treatment of diabetes mellitus and essential hypertension is based on the belief that these two syndromes are due to some abnormal function of the pituitary or adrenals and that this abnormality can be corrected by irradiation of these structures. Among the patients having essential hypertension, forty-three either had an inadequate amount of treatment or could not be followed. Of those who had an adequate amount, ninety-nine definitely improved both as to relief of symptoms and as to reduction of blood pressure. Of the twenty-one patients having hypertension and diabetes, eight were improved as to both conditions, seven as to hypertension only and three as to diabetes only, and three either had an insufficient amount of treatment or could not be followed. Of the forty-six diabetic patients, ten received an inadequate amount of treatment. Of the remaining thirty-six, twelve were unimproved, five reported symptomatic improvement but without change in their carbohydrate tolerance and nineteen experienced some improvement both symptomatically and as regards carbohydrate tolerance. The best responses have been obtained with small doses of x-rays. Of 159 cases reported as being treated by other men, 137 are said to have experienced improvement following treatment. The final evaluation of this form of treatment depends on time and the accumulation of a large series of cases. The authors do not offer the treatment as a cure but as an addition to the treatment of these two syndromes.

Experiments in Sensitivity to Poison Ivy—Field and Sulzberger experimentally sensitized 7 persons presumably never previously in contact with poison ivy by the application of skin tests with an 8 per cent acetone extract of the leaf. The incubation period required for the development of this induced eczematous hypersensitivity was from nine to ten days. When the subject was given patch tests after the skin had become sensitized, the time required for the development of the clinically manifest skin reaction regularly was approximately from twenty-four to seventy-two hours depending somewhat on the concentration of the extract applied. The sensitization was of such a degree that the individual previously not reacting at forty eight hours even to concentrations as high as 1:100 later reacted strongly to a 1:1,000,000 dilution of the extract employed. The subject showed marked variations in reaction to the same extracts on repeated patch testing. There were variations depending on the time of the test and also constant variations depending on the skin area tested. The result not only warns against drawing too definite conclusions from one or a few patch tests applied at the same time but also serves to explain certain discrepancies of results and unexplained variations in reactions as well as false negatives.

Respiratory versus Gastro-Intestinal Infection in Poliomyelitis—Flexner points out that the debated problem of the gastro-intestinal versus the respiratory mode of infection in poliomyelitis has been restudied by several investigators recently, with conflicting conclusions. Toomey's methods are so severe and artificial that his results cannot be regarded as simulating a natural mode of infection. The author repeated the tests of Kling and Levidits but in a far more comprehensive manner than was followed by them, and like Clark and his associates who early repeated them he has failed to confirm them. He does not find *Macacus cynomolgus* and *rhesus* to differ in any essential way in their response to the presence of the virus of poliomyelitis in the body. *Cynomolgus* do not respond to virus introduced into the stomach when con-

tinuation of the buccal and nasal cavities is avoided, they respond, as do *rhesus* to virus directly injected into the intestine when the virus passes into the intestinal wall and makes the necessary nerve fiber contact. Both *Macacus cynomolgus* and *Macacus rhesus* that have resisted feedings of virus are subject to nasal instillations of the same strains of virus and in the same degree. On the basis of his present experiments the author reaffirms the conclusion previously arrived at by him and his co-workers, and confirmed independently by investigators in Europe and America, that the only established port of entry of the virus of poliomyelitis into the central nervous system of man is the nasal membrane and especially the olfactory nervous areas in that membrane.

Streptococci from Human Gastro-Intestinal Ulcerations and from Bovine Mastitis—Torrey and Montu made a comparative study of authentic strains of the Bargaen diplo-streptococcus of ulcerative colitis of selected enterococci associated with the same disease of representative strains of Saunders streptococcus of gastroduodenal ulcers and of streptococci associated with bovine mastitis which leads them to the following conclusions. The Bargaen strains although exhibiting certain features in common such as the splitting of raffinose differed greatly in resistance to heat and in their antigenic constitution as indicated by agglutination and agglutinin absorptions. One strain exhibited all the biochemical attributes of an enterococcus and three others the marked resistance to heat characteristic of the enteric streptococci. It would seem proper to classify them as variants of the enterococcus. The strains from gastric ulcers and gastric ulcer carcinoma tissue did not show as great a degree of cultural and serologic homogeneity as has been reported by Saunders for other series of cultures isolated from these sources. A connecting link with the Bargaen group was indicated by the close serologic relationship of two of them to a type Saunders strain. The other three Bargaen strains were agglutinated only to a slight degree if at all, by the four Saunders strain serums. With one exception none of the ten Saunders strains split raffinose. Biochemical and serologic tests indicated only exceptionally any relationship between the streptococci associated with ulcerative processes in the human gastro-intestinal tract and *Streptococcus mastitidis* of bovine origin. On the other hand three streptococcus strains from mastitis milk not related

culturally or serologically to *Streptococcus mastitidis* exhibited such relationships to two enterococcus strains from ulcerative colitis and to certain of the Saunders peptic ulcer and carcinoma strains. These and other observations suggest a bovine origin for certain enterococcus-like organisms capable of invading human tissues.

Pathogenesis of Actinomycosis—The aerobic-anaerobic organisms isolated by Lord and Trevett from the normal mouth appear to be identical with the actinomycetes of the Wolff-Israel type in morphology and staining reaction. The character of their initial growth in bouillon, the readiness with which growth occurs under aerobic conditions and failure to produce lesions characteristic of actinomycosis in animals make it impossible to classify them as belonging to the group of the actinomycetes of the Wolff-Israel type. Organisms of the Wolff-Israel type have not been demonstrated outside the human or animal body and in view of their biologic character it is unlikely that multiplication takes place in the outside world under any ordinary conditions. Implantation of the parasite within the tissue through injury by a foreign body may be a factor. There are many instances recorded in the literature of the presence in the lesions of foreign bodies mostly of vegetable nature, but in the majority of cases there is no history of a foreign body and none is found in the lesions. As the most common site of the disease is the region about the head and neck with abdominal involvement next in frequency and the pulmonary form in a relatively small proportion of cases the buccal cavity is to be regarded as the port of entry, with secondary invasion of the neighborhood by direct extension and the abdomen and lungs through swallowed or inhaled organisms.

Prevention of Anaphylactic Shock—Fraenkel and Pulvertaft found that repeated doses of BCG emulsion in saline solution produce a state in the sensitized animal which protects it from the anaphylactic shock due to horse serum. With the desensitizing or shocking dose much in excess of the fatal dose the protection becomes less effective. Single small doses

before or after sensitization do not induce the state of protection against serum shock. The injection of attenuated or killed bacilli or the production of abscesses with other bacteria does not induce any degree of protection.

Effects of Vaccine Injections on Skin Sensitivity—It appears to Touart and his co-workers that an increase in skin sensitivity after vaccine injections occurs only when too large a dose of killed bacteria or some other factor, such as the use of a mixed vaccine, establishes a reservoir of antigenic material in or beneath the skin. Under these circumstances a lesion results which has the effect of a focus of infection. An increase in bacterial allergy may follow if a series of such injections is given. Treatment injections with vaccine reactions as guides are adjusted by the authors in bulk and concentration so as to produce a minimum of local reaction. Thus the production of focal lesions and an increase in hypersensitivity have usually been avoided. Retests in patients under treatment with mixed vaccines composed of one organism which produced a large late local reaction after the original skin tests and of others which produced smaller reactions have at times revealed increased skin sensitivity to some of these organisms. At other times it was seen after retests that reduction in skin sensitivity was proceeding at a more rapid pace in the case of some of the organisms contained in a mixed vaccine than in the case of others. Further injections of the same organisms but as single strain vaccines have appeared to rectify these inequalities. The intense local reaction produced by the organism in a mixed vaccine to which the patient is most sensitive seems to localize the less potent organisms within the reaction to such an extent that little desensitizing effect can be produced by them. Such a local reaction may even act in a manner similar to that of a focus of infection from which sensitizing doses of the weaker bacteria repeatedly escape. Not only did a diminution or disappearance of the delayed type of skin sensitivity accompany relief of symptoms but also these two synchronous phenomena proceeded in direct proportion to each other. The foregoing suggests that the symptoms which were relieved may have been allergic manifestations set up by the particular organisms recovered from the patient and used in treatment. So far as specific desensitization to the particular organisms used in treatment is concerned no greater changes were produced by treatment in unimproved patients than those which would have occurred without treatment. Persistence of an undrained focus of infection seems to be the usual cause of failure of autogenous vaccine therapy to be followed by improvement of symptoms and by regressive changes in skin sensitivity.

Effects of Hyperpyrexia on Blood Chemistry—Simon observed the effects of artificial fever on the blood count, urine and blood chemistry. This study is based on seventy one treatments given ten patients. He noticed that during treatment the blood is first diluted but later becomes concentrated. The urine shows an increasing alkalinity and occasionally clearing of albuminuria. The blood sugar level shows a marked rise with no glycosuria when the level reaches to the accepted renal threshold or beyond. Creatinine and nonprotein nitrogen show more of an increase than can be considered due to concentration. Blood chlorides decrease approximately 2 per cent. The white blood count is increased by fever treatments. This is first noticed in the granulocytes and is due partly to production of immature forms and partly to mobilization of older types. Any experimental work of this nature should be under standard conditions and should cover a sufficiently large number of cases to allow for individual variation.

- Therapeutic Quatran Malaria in Treatment of Neurosyphilis Among Negroes G. C. Branche Tuskegee Ala.—p. 177

Simmonds Disease—Dunn cites a case of Simmonds disease (multiple ductless glandular sclerosis, Faglia) in a girl aged 13 years with a presumptive early and successful result of

treatment The treatment consisted in the daily hypodermic administration of large doses (2 cc) of the anterior pituitary liquid (Armour) and equally larger weekly doses (10,000 rat units) of estrogenic substance (progynon-B, Schering) The period of time that treatment will have to be maintained is not known However, it has been and will be consistently reduced as normality is maintained Concerning the subject of Simmonds' disease, it is believed that Falta's classification as and the definition of "multiple ductless glandular sclerosis" more typically expresses the pathologic and clinical picture of the syndrome now known as Simmonds' disease (hypophyseal cachexia) Further, it stresses the pluriglandular therapy required to offset the pathologic atrophy ensuing in the various endocrine glands and the structures they control The success of the treatment in this particular case would seem to verify, at least in part, this conclusion

- *Effects of Excessive Ingestion of Sodium and Potassium Salts on Carbohydrate Metabolism and Blood Pressure in Diabetic Children I McQuarrie W H Thompson and J A Anderson Minneapolis—p 77

Availability of Iron in Whole Wheat—Vahlteich and her associates fed young rats depleted to hemoglobin levels averaging 33 Gm per hundred cubic centimeters of blood at 8 weeks of age as supplements to fresh whole milk (1) whole wheat (3 Gm), yielding 0.1 mg of iron and 0.02 mg of copper, (2) whole wheat (27 Gm) with all the starch dextrinized, furnishing the same amounts of iron and copper as 1 (3) 0.1 mg of iron as ferric chloride and 0.02 mg of copper as copper sulfate Hemoglobin regeneration was best on the predigested wheat, next best on the natural wheat finely ground and poorest on the mineral supplements, the gains in six weeks amounting respectively to 96, 76 and 7 Gm of hemoglobin per hundred cubic centimeters of blood The authors believe that the ease of digestion of the dextrinized wheat has been the factor causing the better hemoglobin regeneration on this than on the wheat finely ground but not predigested

Effects of Sodium and Potassium Salts on Carbohydrate Metabolism and Blood Pressure—McQuarrie and his collaborators found that, when ingested in amounts varying between 1 and 2 Gm per kilogram of body weight daily, sodium chloride exerts a favorable influence on the carbohydrate metabolism of diabetic children taking simplified diets low in potassium This effect is usually observed on the second or third day At the same time both the systolic and diastolic blood pressure levels are elevated significantly Sodium appears to be chiefly responsible for these effects since other salts of this element as well as the chloride exert similar though less marked, effects Potassium chloride has diametrically opposite effects on both glycosuria and blood pressure In terms of chemical equivalents, potassium completely antagonizes the effects of sodium when given simultaneously in amounts as little as one third that of sodium The studies were carried out on one normal and four diabetic subjects from 13 to 15 years of age The physiologic mechanisms involved in these reactions are at present obscure but are being further investigated

Treatment of Cancer of Stomach—Walters says that the proper treatment for carcinoma of the stomach is surgical removal whenever possible Every patient who has cancer of the stomach regardless of how extensive should be allowed the benefit of surgical exploration of the lesion provided distant metastasis is not demonstrable In from 10 to 15 per cent of those cases in which the lesion, on roentgen examination, appears to be inoperable because of its extent, surgical removal of the lesion can be accomplished Large malignant lesions of the stomach will often be found to be of a low degree of malignancy, to be sharply demarcated and to present no involvement of lymph nodes Removal of such lesions by partial gastrectomy gives a high incidence of permanent cure and this is particularly true in elderly patients At the Mayo Clinic the finding of an extensive carcinoma, localized in the stomach, or even of one associated with involvement of lymph nodes, is viewed from the standpoint that unless the lesion is removed, the patient is doomed to early death In several cases total gastrectomy has been performed successfully at the clinic, and patients have lived and been comfortable two and three years subsequently That such an operative procedure can be carried out in suitable cases with great benefit to the patient has led to the impression that all gastric lesions should be removed unless they have invaded adjacent structures to the extent that the carcinomatous process cannot be removed in its entirety It is not an uncommon experience to find that a growth which is examined while the patient is straining under light anesthesia appears to be unremovable but under deep anesthesia may be seen to be readily removable It is not the age of the patient but his general condition that is a factor in the surgical mortality The author has found it of value to approach all extensive lesions of the stomach through a left rectus incision, as suggested by Balfour In general, a posterior Polya or an anterior Polya-Balfour type of anastomosis is the most satisfactory type of reconstruction following extensive gastric resection for malignant disease However in certain instances the original method of Billroth, in which the stomach and duodenum are anastomosed, has

worked out to advantage, although the greatest field of its applicability is in the presence of benign gastric ulcers bleeding duodenal ulcers and recurring ulcers. When extensive gastric resections have been performed on elderly patients, particularly in the case of subtotal or total gastrectomy, jejunostomy as a means of providing a temporary method of feeding has a decided advantage. During this time oral administration of fluids is restricted to assist in healing of the anastomosis. This is of particular value for patients who have lost a considerable amount of weight and who have been debilitated as a result of carcinomatous obstruction. The presence of abnormal gastric lesions from 1 to 1.5 cm in diameter can be detected by a competent roentgenologist. Many small lesions of the stomach, which appear to be benign on roentgen examination and even at the time of operation, have proved microscopically to be malignant.

Primary Carcinoma of Lung—Overholt points out that excision of the entire lung on one side is technically possible that the consequence of such a procedure is not incapacitating and also that a diagnosis of primary malignant condition of the lung can be made before the patient reaches the necropsy table. An analysis of the cases in his series and the experiences of others show that the large majority of all primary carcinomas of the lung originate in a major division of the right or left main bronchus. Therefore, the majority of these lesions can be actually seen early in their development and a biopsy obtained by means of the bronchoscope. Cough and hemoptysis occurred in a large proportion of all cases early in the course of the disease. This warning sign should be heeded and if no adequate explanation is forthcoming after sputum and roentgen examinations, the patient should be subjected to bronchoscopy. In the early stages of stem bronchus lesions the lesion itself does not cast a shadow on the roentgenogram. The roentgen diagnosis depends on secondary evidences of growth, namely, atelectasis. In all cases of a proved malignant manifestation exploratory thoracotomy is indicated if metastasis cannot be demonstrated. In peripheral lesions exploration is justified without a positive biopsy diagnosis. The thoracic exploration may be the only

possible way to settle the diagnosis at a time when the growth is in the operable stage. Any form of irradiation is ineffective. Five successful pneumonectomies are reported—three for malignant and two for suppurative disease.

Hyperglycemia and Dementia Paralytica—Blackford and Venable cite two cases of hyperglycemia and dementia paralytica. They explain convulsions in relation to diabetes on the basis of an overdose of insulin. Neither patient had ever had insulin at the time of her first convulsion. Convulsions are not infrequent in dementia paralytica, and the headaches, disorientation and at times marked euphoria are, especially in view of the spinal fluid reports, pathognomonic of dementia paralytica. The authors know, therefore, in spite of the absence of necropsies, that in both cases there was extensive destruction of the brain substance. It is not unreasonable to assume that the vital basal structures were damaged. The evidence against the presence of diabetes mellitus independent of the syphilis in the first case is not conclusive. In the second case dementia paralytica seems an adequate explanation of the whole picture. The patient exhibited glycosuria only when in a convulsive state, and, in spite of excessive indulgence in sweets, she gained weight steadily until the time of her death. Her sugar tolerance curve, though high, is in keeping with that reported from time to time in cases of cerebral lesions.

Evaluation of Serodiagnostic Test for Syphilis—Seneac and his associates declare that the plan in their study differed from that of the conference of the League of Nations in that the serums were sent to each of the thirteen participants who

were able to test them in their own laboratory, in most instances probably along with their routine serologic work. In other respects the procedure followed in the main that of the League of Nations conferences. Four participants performed complement fixation tests and nine performed flocculation tests. A total of 1,017 blood specimens and 220 spinal fluid specimens was furnished to each participant. The specimens were collected in various parts of the country and, depending on the distance that they were to travel, were sent by ordinary special delivery or by special delivery air mail. The average in sensitivity of the nine flocculation tests was 80.3 per cent, and that of the complement fixation methods 75.1 per cent. The previously published conclusions of the committee are reviewed in part in order to emphasize again their conception of the present situation in the serodiagnosis of syphilis.

Chronic Mastitis and Coincident Gynecologic Lesions

—According to Taylor, the difference of opinion expressed by various observers and the easily found exceptions to the Rosenberg conception indicate that the cycle of a general premenstrual epithelial proliferation and postmenstrual regression has probably been exaggerated. A premenstrual hyperemia of the breast is, however, obvious from the gross changes in the size and the weight of the breast and the deepening of the color of the areola. Microscopic evidence of this vascular change is found in the greater definition of the lobule and in the alteration of the character of the intralobular connective tissue. The painful breast in its simplest form exhibits an increase in these premenstrual vascular changes. To refer the abnormal premenstrual swelling of the breast to excessive epithelial

proliferation or the pain to the distention of the ducts with desquamated cells is contrary to many histologic observations. The tissue in the milder forms of the painful breast may therefore appear almost normal under the microscope or may show excessive "edema" of the intralobular connective tissue. In the cases presenting pain and marked nodularity there may be evidence also of irregular fibrous tissue and epithelial proliferation. The histology of the painful hypertrophies of this series was in general similar to that of the painful, nodular breast. The histology of the breast with discharge from the nipple is variable and includes duct dilatation, stasis and catarrhal inflammation, frequently with secretion and hyperplasia of the epithelium and fibrosis and round cell infiltration of the connective tissue.

Healing of Gastric Defects—Howes and his co-workers administered excessive amounts of pepsin and hydrochloric acid to cats with mucosal defects in the stomach and observed the rate and character of healing. The results are compared with the healing of similar defects in a group of animals receiving equal amounts of hydrochloric acid without pepsin and with controls receiving neither acid nor pepsin. The concentration of hydrochloric acid given to the majority of the cats ranged between hydrogen ion concentration 1 and 14. The failure of these experiments to produce chronic ulcers does not invalidate the clinical concept of the causal relationship between gastric juice and the chronicity of ulcer, for the defense mechanisms against the action of potent gastric juice were relatively undisturbed. The gastric juice of the patient with chronic peptic ulcer has no more capacity to cause an acute mucosal ulceration to become chronic than does artificial gastric juice. In general the stomach, even when injured, has the ability to cope with destructive digestive juices remaining in the lumen for long periods of time, provided the defense mechanisms are not too disturbed.

Amniotic Fluid Concentrate and Peritoneal Immunity

—From the experimental and clinical evidence on which Johnson and his associates base their paper, they state that they have definitely proved that amniotic fluid concentrate most effectively meets the requirements to establish peritoneal immunity against infection and adhesions. The only other substance now being employed to any extent as an activator of peritoneal immunity is the bacterial vaccine of Rankin and Bagen with modifications by Steinberg and Goldblatt. Extensive clinical trial and laboratory experiments have proved this agent effective. However, its use is confined to preoperative administration, from forty-eight to seventy-two hours before the abdomen is opened, and the protection afforded by its introduction is attained at the cost of a considerable physiologic and clinical upset and a long immunizing interval. In the authors' experimental work, at least, the product itself has not proved stable. Other substances such as physiologic solution of sodium chloride, pepsin and sodium ricinoleate, were studied as controls and for the purpose of learning their beneficial or destructive qualities in the infected and uninfected animals. The brief immunization interval required in the use of amniotic fluid concentrate makes it adaptable for operative as well as preoperative introduction.

 Significance of Lateral Aberrant Thyroids A. L. d'Abreu—p. 1406

Scurvy—Wood reports a case illustrating that scurvy still occurs in adults. In this instance a dyspeptic diet was the cause of the vitamin deficiency. The case bears out the contentions of Harris and Ray that the cevitamic acid urinary excretion test is a valuable aid in the diagnosis of scurvy. The patient received more than 1,000 mg. of cevitamic acid and excreted only 17 mg., and that was after the test dose of 600 mg. A normal control, after a test dose of 600 mg., excreted 231 mg. There can be little doubt that both children and adults store vitamin C in the tissues, for Harris and Ray have shown that the excretion of cevitamic acid continues at an even rate for many days after complete elimination of the vitamin from the diet, and there is no evidence that human beings can synthesize it. That 1,000 mg. of cevitamic acid was almost completely retained in the body of this patient suggests that her stores were very low. The anemia of scurvy is of interest. In this patient the anemia was moderate and appeared to be orthochromic and normocytic. It was not possible to estimate the reticulocyte response owing to the patient's objections. The bleeding time was prolonged and the blood platelets were normal.

 *Management of Head Injuries R. A. Money—p. 810

Management of Head Injuries—Money considers the following pathologic conditions as being covered by the term head injury: (1) wounds and contusions of the scalp; (2) fractures of the skull and their complications; (3) meningeal and vascular injuries, leading to the various types of intracranial hemorrhage—epidural, subdural, subarachnoid and intracerebral; (4) contusions and lacerations of the brain, with edema and/or hemorrhage leading to the clinical states of traumatic stupor and traumatic delirium (that is, concussion, irritation and compression of the brain); and (5) after-effects of any of the foregoing, including mental deterioration, traumatic neurosis and fits. A consideration of any large series of head injuries on the basis of traumatic stupor will enable them to be placed in three categories according to their condition on admission to the hospital. The first group consists of patients who are deeply unconscious or comatose. These comprise

chiefly cases of injury to the base of the skull with rapid and extensive subarachnoid hemorrhages and hemorrhages from the dural sinuses. The patient's condition becomes progressively worse, whatever is done, and death occurs within the first twenty-four hours and usually within the first eight hours. In the second group patients are of two main types: 1. Patients who have regained or are already regaining consciousness but are dazed and restless, with immediate retrograde amnesia. Provided a progressive return of the faculties proceeds, the prognosis is good, whatever the injury. 2. Patients who were primarily unconscious but have recovered and relapsed into a secondary unconsciousness or stupor. Unless careful observations have been made on admission or shortly afterward, it may be difficult to estimate the length of the lucid interval, the depth of this secondary stupor (the crucial point) and the existence of localizing signs. The classic cases of extradural and massive subdural hemorrhage fall into this group, and for them active operative intervention (subtemporal craniectomy, often bilateral) is essential. If the stupor is relatively light and no paralysis is observed, only edema may be present, and recovery will occur spontaneously or by the aid of dehydration methods without major operation. The third group consists of patients who are stuporous or lightly unconscious on admission and who remain uncooperative and unresponsive for hours, days or weeks. Despite this lack of cooperation, many useful observations and examinations can be made. The condition of the patients, thus revealed, is a gradual and progressive one toward recovery, anxiety will be relieved, and there is no need for major surgical intervention. These are usually cases of severe contusions and lacerations. The early adoption of the upright posture in a special bed is advocated, and the use of bromides and the barbiturates for restlessness in preference to morphine is urged. A routine is set out for the prevention and control of hyperthermia. The indications for lumbar puncture, both diagnostic and therapeutic, and the administration of hypertonic solutions are stated. The routine use of a simple spinal glass manometer to determine accurately the intracranial tension before deciding on active therapeutic measures is advised. The indications for and technique of operations for scalp wounds and fractures are considered in detail. The repair of defects in the cranial vault by bone grafts from the ilium is advocated. Failure of compensation and the onset of compression call for operation. Subtemporal decompression is usually sufficient to enable evacuation of the clot. Early evacuation of localized intracerebral hemorrhage to prevent the onset of fits is advocated.

 *Systemic Salmonella Infections in Man Clinical and Bacteriologic Study C. J. Wu and S. H. Zia—p. 1217

Systemic Salmonella Infections—Wu and Zia state that in the last fourteen years 691 cases of typhoid paratyphoid group fevers have been admitted to the Peiping Union Medical College Hospital, their relative incidence being typhoid 84.1 per cent, paratyphoid A 9.4 per cent, paratyphoid B 3.2 per cent and paratyphoid C 3.3 per cent. The clinical symptoms of the systemic Salmonella infections are indeed variable and almost identical, no matter which organism is the underlying cause. Many even simulate moderately severe cases of Bacillus typhosus infection. Eleven of the eighteen cases of Bacillus paratyphosus, Corynebacterium suisstifer infections occurred in the last two years. The comparative scarcity of the natural Bacillus paratyphosus B infection in Peiping leads the authors to wonder whether it is wise to continue to include this organism in the preparation of vaccine for prophylaxis against enteric infections. The United States Army vaccine now does not contain Bacillus paratyphosus B, because it has been found to be no longer necessary. If studies in other parts of the country confirm this relative low incidence, it may be time to leave out Bacillus paratyphosus B in the preparation of vaccine, which would incidentally reduce much of the severe reaction now resulting from its use.

Skin Grafting M Grinda—p 2053
Morbid Determinism of Dolichocolon J Tauzin—p 2055

Malaria and Henry Reaction—There are according to Marchoux and Chorine, only two ways of diagnosing malaria. The parasite must be discovered in the blood or its pigment must be found. For the determination of the latter the Henry reaction is especially interesting though it does not have the specificity originally credited to it. It rests solely according to most investigators, on a change in the serum. The change consists especially in an increase in the coefficient of euglobulins precipitable by distilled water. This serum disequilibrium is constant in malaria but is not confined to it. A positive result gives an erroneous diagnosis of malaria in from 5 to 7 per cent, but a negative reaction is false in less than 1 per cent. The reaction is, however, inhibited at the time when the microscope shows the parasites in the blood. Certain technical factors are important. Thus blood for the test should not be taken at the time the parasites appear in the blood and it should be taken from the fasting person. It is important to test the blood soon after removal, as the time factor is important. Finally the distilled water method gives the most certain results. Of 335 patients examined the reaction was negative in 253, positive in sixty-two and doubtful in twenty. In patients who had acquired malaria in the colonies the reaction was positive in from 35 to 40 per cent during the first six months of their return and fell almost to zero after two years. The authors feel that this reaction may confirm other evidence that malaria apparently cured is so in actual fact.

Time of Circulation and Venous Pressure G Ferrari and F Ferroni—p 87
Therapeutic Action of Antithyroid Serum in Hyperthyroidism and Exophthalmic Goiter T Gelli—p 91
Sexual Functions and Tuberculosis A Campani—p 92

Artificial Pneumomediastinum—Condorelli uses air injected into the mediastinum, as a contrast medium for roentgen visualization of the mediastinal structures. The punctures are made as follows. The patient is put in the dorsal position without any pillow, having his neck in extension. If the air is going to be injected in the anterior mediastinal cavity the central point of the suprasternal fossa is compressed by the surgeon with the index finger of the left hand and a needle 10 cm long and bent at an angle of 120 degrees 4 cm from its point is introduced to a depth of from 2.5 to 3.5 cm and then inclined so that the point of the needle follows the posterior aspect of the manubrium sterni, which is the anterior boundary of the cavity. Aspiration through the needle, temporarily connected to a sterile syringe, is performed to avoid insufflation into a blood vessel. The pain caused by the puncture is slight and no accidents follow. If the air is to be injected into the posterior mediastinal cavity, the needle is introduced at the center of the middle line of the neck, at a point two finger-breadths above the fossa suprasternalis, as if for a tracheal puncture. When the point of the needle reaches the anterior wall of the trachea, the needle is inclined downward, tangentially to the trachea to a point 2 cm below the suprasternal fossa. At this point the air insufflation can be performed. As a preliminary work for the establishment of the aforementioned technique the author made injections of two different colored liquids into the mediastinum of cadavers and found that there is an anatomic septum separating the mediastinal anterior and posterior cavities, which is formed by the deep layers of the middle cervical fascia and the posterior aspect of the pericardium, in front and by the mediastinal pleurae at the sides. The author verified the boundaries of the mediastinal cavities and the routes through which the colored liquids disseminate themselves after the injection. His verifications clarify the significance of the roentgen shadows of the mediastinal structures in

artificial pneumomediastinum and the mechanism of expansion of the air injected. The author calls attention to the importance of artificial pneumomediastinum in the roentgen examination of the mediastinum for the diagnosis of pleuromediastinal diseases.

*Spherical Calcium Concretions and 'Corpora Amylacea' in Epididymis A Marsella—p 12
Raynaud's Disease Recurrence After Sympathectomy Cases P Valdout—p 32

Spherical Calcium Concretions and "Corpora Amylacea" in Epididymis—Marsella found spherical bodies, equal to those that have been described in other organs under the name of amyloid bodies, in the efferent ducts of the head of the epididymis. In his case the larger part of the bodies were calcified. The author says that, because amyloid bodies have no specific characteristics of identification and their structure varies in different organs, in the same organ and even in the same section, it is advisable to distinguish as "spherical calcium concretions" the formations in which calcium predominates and as "amyloid bodies" those that have a concentric lamellar structure and do not have histochemical reactions to calcium. Spherical calcium concretions in the epididymis may originate in the detachment and homogenization of epididymal cells, especially epithelial cells, in amyloid bodies and in precalcified and other small accumulations of inorganic substances, independent of any cellular origin, which form the primary nuclei for the aggregation of the body. Epididymal concretions and amyloid bodies are found free in the lumen of the epididymal ducts, while those previously described in the testicle have been found to be in contact with the walls of the testicular tubuli, circumscribed by epithelial or other cells, or as migratory bodies in the interstitial connective tissues. The necessary conditions for the production of the formations are not only the detachment and degeneration of the epithelial cells and the modifications of the epididymal fluid, such as coagulation and stasis of the fluid in the tubuli but also, and especially, the lability of the epithelial cells and the rupture of the equilibrium of the colloids and of the calcium metabolism. The coincidence of these conditions explains the formation of the concretions in the epididymis on the one hand and its origin in alterations independent of the detachment of epithelial cells on the other. The appearance of both spherical calcium concretions and corpora amylacea is related neither to certain diseases nor to the age of the patient in whom they appear.

Cranio-Encephalic Topography—Bertola describes a new method of cranio-encephalic topography to mark on the head the position of the cerebral fissures. The technique is as follows. A sagittal line is drawn from the subnasal point to theinion. The central point of this line is marked, the line being divided into an anterior and a posterior portion. The posterior portion is divided into three equal parts, which turn out to be the rolandic, sylvian and mal points. A line is then drawn from each of these three points to the retro orbital tubercle, which is located at the center of the posterior edge of the external orbital process. The three lines result in the rolandic, sylvian and temporosinusual lines. The fissure of Rolando corresponds to the upper two thirds of the rolandic line. The sylvian fissure corresponds to the inferior two thirds of the sylvian line, beginning at the point of intersection of this line with a perpendicular line drawn from the center of the zygomatic arch. At the point of intersection of these two lines the anterior branch of the middle meningeal artery is found. The transverse (horizontal) portion of the transverse sinus corresponds to the posterior third of the temporosinusual line. The middle

branch of the middle meningeal artery is found at the point of union between the inferior third and middle third of the rolandic line. The course of the posterior branch of the middle meningeal artery corresponds to a line that bisects the angle formed by the sylvian and temporo-sinusal lines. The correspondence between the cerebral fissures and the cranial lines, on the one hand, and between the course of the three branches of the middle meningeal artery and the cranial points of reference, on the other, according to the method of the author, is exact. The author, in carrying out his verifications used one half of the head for performance of his own method and the other half for either Kronlein's or Chipault's methods. His topographic marks agree with those of Kronlein's method, not with those of Chipault's. His method, however, is different from both Kronlein's and Chipault's. The author concludes by saying that his method can be applied to heads of any cephalic index. The cephalic indexes ranged between 69.23 and 88.96. His method is the first in which the course of the three branches of the middle meningeal artery is topographically marked. It is proportional, but of easy technic and application.

Beitrage zur klinischen Chirurgie, Berlin

- Reconstruction of Nose Shrunken by Tuberculous Process E. Eichhoff—p. 107

Plastic Operations for Hydronephrosis—According to Schaffhauser, the experience with the cases of hydronephrosis in which treatment was given at Clairmont's clinic (Zurich) suggests the advisability of a wider application of conservative plastic surgical intervention than has been practiced heretofore. Little difficulty is experienced in deciding on the type of operation in the cases of completely destroyed kidney represented by a mere sac. It is in cases of hydronephrosis of average size that diversity of opinions exists. There are no definite indications here, every case requiring careful consideration of a number of factors, which frequently become apparent only after free exposure of the kidney. Infected hydronephroses limit but do not exclude indications for plastic conservative surgical intervention. The role of mechanical factors in the pathogenesis of hydronephrosis is as a rule underestimated and the possibilities of restoring renal function after the removal of the mechanical cause not fully appreciated. The author believes that with more frequent recourse to conservative plastic operations it will be possible to save more functioning kidneys than has been the case in the past.

Alterations in Duodenal Ulceration—On the basis of 200 roentgenologically investigated cases, 169 of which were controlled by operative intervention, Ruckenstein concludes that twin ulcers occur in the upper portion of the duodenum with considerable regularity. Because of the tendency to heal, the association of an ulcer with a scar is not unusual. The localization of duodenal ulcers is confined to definite areas in the intestinal wall with a corresponding deformity of the duodenal bulb. Consideration of the latter suggests the possible location of the ulceration. The author believes that the large single ulcer is frequently the result of coalescence of two ulcers.

- Time Relations Between Cardiac Action and Electrocardiogram W. Knoll, L. Girones and W. Goerke—p. 140

Pathologic Pigmentations and Their Treatment—Hoff shows that many pathologic pigmentations of the skin are connected with a deficiency of vitamin C and can be counteracted

by the administration of this substance. Vitamin C deficiency may be caused by exogenic factors, namely, by deficient vitamin C content of the diet. In this connection the author mentions scurvy, in which severe pigmentations are often noted on portions of the body that are exposed to light. These pigmentations subside together with the other symptoms following the administration of sufficient quantities of vitamin C. The author points out that the physiologic pigmentation of the skin (produced by sunlight or quartz lamp) is likewise reduced by vitamin C. Vitamin deficiency may result also from a deficient resorption of vitamin C. The author thinks that pathologic pigmentations in the course of achylia gastrica (carcinoma of the stomach and pernicious anemia), in pancreatic disturbances and in chronic gastro-intestinal disturbances may perhaps be explained in this manner. Vitamin C deficiency may also be of endogenic origin, as, for instance, in case of destruction of the adrenals (Addison's disease). However, even the pathologic pigmentations that can be traced to none of these factors occasionally yield to the administration of vitamin C. The author cites a case of generalized scleroderma with symptoms of Addison's disease in which abnormal pigmentations were improved by vitamin C. The symptoms of scleroderma improved considerably in response to the combined administration of vitamin C, adrenal cortex extract and an extract of the anterior hypophysis. The relations of the abnormal pigmentation with other secretory glands and with the sympathetic nervous system are discussed.

Diagnostic Value of Trichophytin Reaction—Kniere says that the intracutaneous trichophytin test is estimated differently by various authors. Opinions differ on the optimal degree of dilution of trichophytin, the interpretation of the skin reaction, the time required for the final evaluation and the diagnostic value. Because of this lack of agreement on the test, the author decided to study it on persons with various skin disorders and on persons without cutaneous disturbances. He tested 115 persons varying in age between 7 and 70 years. He used trichophytin dilutions of 1:200, 1:100, 1:50 and 1:10. In the final evaluation he considered the reactions that had been produced with the 1:50 dilution after a period of thirty-six hours. He gives tabular reports of the results of his tests and reaches the conclusion that, provided the test is employed with due criticism, it has some diagnostic value. However, it cannot be the only criterion in the differentiation between mycotic and nonmycotic disorders, for the test is positive in from 10 to 35 per cent of persons who are free from mycotic disorders, and it is negative in from 25 to 45 per cent of the patients who have a mycosis.

- Prophylactic Use of Injectable Liver Extract M. Landsberg—p. 77
- Problem of Hypertension in Circulatory Organs J. Pal—p. 78

Diagnostic Significance of Schröder's Cancer Hair—Frick and Meduna point out that, although the cancer reactions have been given considerable attention in recent years, some of the secondary signs and symptoms have been largely disregarded. In this connection they call attention to Strumpell's observation that patients with cancer, particularly those with gastric carcinoma even if they are of a rather advanced age, rarely have gray or white hair. Other observers have noted frequently a rather youthful appearance in patients with incipient carcinoma. Schröder studied the hair growth of patients with cancer and found that carcinoma patients have a smaller or larger number of deep black coarse and dull hairs on the parts of the head that are exposed to light particularly the temples. The diagnostic significance of this sign was denied by the majority of clinicians. The differences in the evaluation of Schröder's cancer hair induced the authors to investigate this sign in 300 patients of the department for internal diseases (a considerable proportion of whom had cancer) and in some healthy persons. They searched for Schröder's cancer hair at the frontal and temporal hair margins and also at the nape of the neck and found it in approximately 25 per cent of their

patients. In comparing the relationship between the occurrence of the cancer hair and diagnosis of carcinoma they found that the described anomaly of hair growth was missing in none of the patients with cancer. It was observed chiefly on the frontal and temporal hair margins, but occasionally (mostly in men) at the nape of the neck. In a number of the cancer cases, the members of the family (siblings, children and grandchildren) were also examined and it was found that the anomaly of hair growth was present in a large number, occasionally even in rather young persons. The authors conclude that the absence of Schridde's cancer hair seems to be a sign for the absence of cancer or of a carcinomatous predisposition; however the presence of this hair is no proof for the existence of a malignant tumor but the probability of the development of a cancer seems to be greater in the persons who have this hair than in those who do not have it. They think that the demonstration of Schridde's cancer hair is of about the same value for the determination of a carcinomatous predisposition as is the knowledge of cases of cancer in the ancestry. In view of the fact that correct family anamnesis is difficult to obtain, an objective sign, such as cancer hair, is of considerable importance.

Training and Further Education of Young Persons in Sanatoriums for Tuberculous Patients H. Brugger—p. 271

Segregation of Patients with Open Incurable Tuberculosis—Hanke advises the segregation of patients with open incurable tuberculosis in special institutes, in the interest of public welfare. He points out that it is the purpose and aim of the segregation of these patients to remove these disseminators of bacilli from healthy persons and thereby prevent the further spreading of tuberculosis. He relates his experiences in an asylum, in which fifty patients with open tuberculosis were taken care of. He considers suitable for residence in such an institute the patients who had a cirrhotic productive form of tuberculosis; are free from fever and are not bedridden. Patients with the exudative forms and with constant fever, however, should remain under hospital care. Among the patients who were admitted to the author's institute for segregation, he found some who were not incurable but quite amenable to surgical treatment. Some of these patients refused to submit to such treatment, but the author points out that it should be impressed on them that they have obligations toward their families as well as toward the public, that is, toward those who have to bear the burden of their support. This responsibility toward their family and the public, whom they expose to the danger of infection, should be impressed also on patients with open tuberculosis who have been segregated for some time but who then demand to be discharged in order to return to their families. The author thinks that, in order to overcome the resistance of some of these patients, it might become necessary for the state to intervene by means of a law for the compulsory segregation of patients with open incurable tuberculosis.

Occurrence of Bovine Bacilli in Human Tuberculosis—Groh describes his studies on thirty-seven patients with pulmonary tuberculosis, forty-eight with renal tuberculosis, five with testicular tuberculosis, thirty-one with tuberculosis of bones and joints and some with other forms of tuberculosis, the total number being 149. He points out that in previous studies on the development of human tubercle bacilli he had found that in the majority the strains contained also those that he had seen in cultures obtained from tuberculous organs of cattle. This observation induced him to make further studies. Among his 149 cases he found only one in which bovine bacilli were not detectable but in all of the remaining 148 cases he found the human as well as the bovine type of tubercle bacilli. He demonstrated this by microscopic studies as well as by the culture method. The relative quantity of the human and bovine bacilli differed in the various cases. In some there were many

that is, they were present in excess of the human type, in others the human and bovine types were present in about equal numbers, while in still others the bovine type was present in only small numbers. In some cases the presence of bovine bacilli was corroborated by animal experiments. The frequent concurrence of the bovine and human types of tubercle bacilli suggested to the author the possibility of a mutation of human into bovine forms or vice versa. He gave attention to this problem in his investigations but was unable to find corroborating evidence for a mutation.

*Rare Forms of Micturition Disturbances in Women (Sclerosis of Sphincter Urethral Stenosis) H. Friedrich—p. 212

Ascites in Nephropathia of Pregnancy E. Junghans—p. 217

Operations for Urinary Fistulas and Incontinence—Martius points out that recent studies on the closing mechanism of the bladder have shown that this mechanism is somewhat different from what has been hitherto believed. Careful studies on the floor of the bladder, proceeding from the inside out, disclosed muscle fibers arranged in loops, the sides of the loop pass along the anterior wall of the bladder and the curve passes posteriorly around the vesical orifice. After these fibers have been removed, a loop of muscle fibers running in the opposite direction becomes visible. The latter muscular loop was the only one that was formerly recognized, it was designated as sphincter trigonalis or sphincter urethrotigonalis. The muscular loop mentioned first had been overlooked by the earlier students. The author gives a schematic diagram of the two muscular loops (lissosphincter loops), which together form the internal vesical sphincter, and shows that the involuntary closure of the female bladder is accomplished by the movement of the two muscular loops in opposite directions (pinchcock mechanism). He shows the importance of these lissosphincter loops in operations for the repair of injuries on the neck of the bladder and of congenital incontinence. He demonstrates that repair of the lissosphincter loop and the simultaneous grasping of the perivesical supporting tissue (the procedure designated by Stoeckel as the "direct muscle plastic") must be the foundation of all operations for urinary incontinence and should never be neglected. The author indicates in a diagram all tissues that may serve as repair material in the correction of vesical fistulas and of urinary incontinence, namely, (1) the vesical wall with lissosphincter, (2) the perivesical supporting tissue with the smooth musculature, (3) the urogenital diaphragm with rhabdosphincter, (4) the levator ani muscle, (5) the bulbocavernosus flap, (6) the corpus or cervix uteri and (7) the rectus sheath with the pyramidal muscles. The author says that he himself generally utilizes the bulbocavernosus flap and he describes how this is done.

Rare Forms of Micturition Disturbances in Women

The first case reported by Friedrich concerns a woman, aged 56. The difficulties with her bladder began seven years before. At first she had symptoms indicating cystitis. There were terminal pains at micturition, the urine was turbid and the last drops were often bloody. For the last several years it became constantly more difficult to void the bladder, and finally spontaneous evacuation was impossible so that catheterization had to be resorted to. In the course of time she learned that she could void her bladder if she introduced a finger into the vagina and pushed the anterior vaginal wall backward during micturition. When the patient first came under the author's observation, neither neurologic nor pelvic symptoms could be found that would explain the condition. However, since the cystoscopically determined so-called barrier formation reminded him of sphincter sclerosis in men, he considered this possibility, although this condition was not known to occur in women. An operation was done on the basis of this probability diagnosis. It was found that the urethral sphincter was unusually narrow. It was decided to excise a wedge-shaped piece from

the posterior sphincter lip, however, when it was found that only a thin layer of tissue separated the vaginal lumen from the neck of the bladder, it was decided to make the excision from the anterior sphincter lip. After this the sphincter ring was wider. With the exception of a severe vesical hemorrhage, the recovery was uneventful. Histologic examination of the excised portion disclosed sclerosis. The author thinks that the occurrence of sphincter sclerosis in women proves indirectly for this disorder in men that such processes are not necessarily preceded by inflammatory processes in the prostate. The second case concerns a woman, aged 42, who had had intermittent disturbances of micturition for about twenty years. In the last two years the woman noted that she had to press harder in order to void the bladder. In the course of the examination it was found that the urethra was impassable for an ordinary catheter, but a thin one (12 Charrière) could be introduced into the bladder after an obstruction had been passed, which was located approximately in the middle of the urethra. After the stenosed portion of the urethra had been dilated, the disturbance in the micturition disappeared. The author points out that, although urethral stenosis is relatively frequent in men, it is rare in women.

*Diabetes and Pregnancy E. Ya. Reznitskaya and P. I. Fomina—p. 1832

*Increased Reactivity to Insulin in Diabetic Patients Under Influence of High Doses of Insulin V. G. Baranov—p. 1838

Pathogenesis of Gout—According to Nishnevich, the etiologic pathogenesis of gout is polymorphous in character. It may be produced by any of the causes bringing about an alteration in the chemistry of the tissues and favoring precipitation and fixation of uric acid salts. Among such causes the author lists the various endocrinopathies and distinguishes a thyrotoxic, an ovarian and a pituitary form of gout. There exists a positive symbiogenesis between uric acid and sodium chloride, expressed by the fact that fixation of urates in tissues aids the mobilization of sodium chloride. Other elements, such as cholesterol, play a part in the phenomenon. Because of a close relationship between the water and the chlorine exchange it is necessary in the study of symbiogenesis in gout to take into account the water balance. Hypo-uricemia and hypo-uricuria rather than hyperuricemia and hyperuricuria are characteristic of a gouty condition. The amount of uric acid in the blood increases with the proper treatment and improvement in the basic disease and leads to hyperuricuria.

Diabetes and Pregnancy—Reznitskaya and Fomina state that the association of diabetes with pregnancy has been seen with greater frequency since the introduction of insulin. A normal course and a favorable prognosis for mother and child are made possible by the employment of rational therapy. In some of the pregnant diabetic patients an increased sugar tolerance was noted in the second half of gestation. This is possibly due to the functioning of the pancreas of the fetus. Hemorrhages toward the end of gestation and after delivery are frequent in diabetic women and may be explained by the increased permeability of the vascular walls. Stillbirths, overweight fetuses and hydramnion are relatively frequent. The more suitable diet is one rich in carbohydrates and poor in fats. Rational insulin therapy is well borne. Cases of glycosuria and of renal diabetes do not require insulin and are to be treated by moderate limitation in carbohydrate intake. Their course of pregnancy, labor and postpartum period run a normal course. Diabetes mellitus even in its grave form is not an absolute indication for artificial interruption of pregnancy, provided the patient is properly treated and controlled (dispensary observation). As a prophylaxis the authors stress repeated examinations of twenty-four hour specimens of urine for sugar and the study of blood curves in cases of glycosuria.

Increased Reactivity to Insulin Under Influence of High Doses—Baranov states that there is an increased reactivity to insulin if the patient has been treated with insulin doses sufficiently high to keep his blood sugar content low

(below 130 Gm) during the day. This increased sensitiveness to insulin is manifested by hypoglycemic curves for some time after the administration of smaller doses. This fact permits lowering of insulin dosage with a simultaneous increase in the quantity of carbohydrates even in the graver cases of diabetes. The author has taken advantage of this fact to simplify the insulin therapy when its continued use is indicated and to terminate it in a number of milder cases. The so called acquired tolerance to insulin probably does not exist and is to be charged to improper methods of therapy.

Supplement 1 112 (Jan.) 1936

*Clinical Experiences with Hypernephromas from 1913 to 1933 on Basis of Thirty Seven Hypernephromas of Kidney and One Hypernephroma of Liver P. Bull—p. 1

Experiences with Hypernephromas of Kidney and Liver—Bull says that, while hypernephromas are highly malignant, the prognosis is not always hopeless even with grave complications. The only effective treatment is removal of the affected kidney as early as possible. Radium or roentgen treatment attempted in some of his cases gave no results. Nephrectomy was done in twenty-six cases (in twenty extraperitoneal, in six transperitoneal) with two deaths from operation, one from pulmonary embolus about six hours after operation and the other from uremia five days after operation. One patient presenting hypernephroma complicated with pyonephrosis died fifteen hours after pyelography (22 cc. of a 25 per cent solution of sodium bromide). Of twenty-four patients, eleven, or 45.87 per cent, lived more than three years after nephrectomy (excluding the two operative deaths, eleven out of twenty-two or 50 per cent). Of the seven or 31.87 per cent, without recurrence, five are living from three and one-half to thirteen years after operation and two died seven and four and two thirds years, respectively, after operation. The thirteen nephrectomized patients who died from recurrence lived an average of three years after the first symptom, and the ten who were not operated on an average of about two years. Hematuria alone was the first symptom in 30 per cent of the cases, hematuria with pain in 30 per cent. The author urges the necessity of pyelography in obscure hematurias and in hematurias of clearly renal origin. In a woman having intermittent fever of unknown cause for seven months, necropsy revealed a hypernephroma of the kidney. In another instance bone metastasis was the first symptom, necropsy two years later showed a hypernephroma the size of an egg, with metastases. While the prognosis seems to depend partly on the size of the tumor, the large hemorrhagic cysts are less malignant than the usual hypernephromas, and size alone does not contraindicate operation. One patient, with local recurrence, is alive twelve years after removal of a cystic tumor weighing 107 Kg., with characteristic hypernephroma only at the hilus. A tumor thrombus in the renal vein or vena cava increases the gravity of the prognosis. Atypical hypernephromas are apparently more malignant than the typical. Solitary metastasis may appear and long continue solitary, such metastases, especially in the bone, should be extirpated if radical removal is possible. Full description of the thirty seven cases is given, together with report of a case of atypical hypernephroma of the liver extirpated from the right lobe of the liver in 1934.

ARE THERE CYCLIC CHANGES IN THE HUMAN VAGINAL MUCOSA?

BERNHARD ZONDEK MD

Professor of the Hebrew University

AND

M FRIEDMAN MD

JERUSALEM, PALESTINE

Hitschmann and Adler showed that the human uterine mucosa undergoes cyclic morphologic changes which depend on the ovarian function. Stockard and Papanicolaou, Long Evans and Allen proved that in rodents not only the uterine mucosa but also the vaginal mucosa and vaginal secretion show cyclic morphologic changes determined by the ovarian function. Hence it is probable to assume that the human vagina is also under the influence of the ovarian hormones. Dierks¹ in 1927 showed that during the menstrual cycle definite proliferative and destructive changes occur in the human vaginal epithelium. In the first days after the beginning of the last menstrual period a division of the vaginal epithelium into three layers is noticeable. This is more strikingly marked during the premenstrual period. Through the early appearance of an intra-epithelial zone of cornification the human vaginal epithelium may be divided into a functionalis, the layer of regeneration and change, and a basalis. Proliferation and sequestration take place in the functionalis. During menstruation the functionalis and partly the intra-epithelial zone of cornification are thrust off, so that a denuded basalis is left on the surface.

The investigations of Dierks have been repeatedly retested. The opinions of the authors vary. Steve², Stenshorn³, Kuckens⁴ and Gisbertz⁵ could not confirm the results of Dierks. Geist⁶ expresses his opinion in the affirmative but emphasizes that not every case shows the characteristic changes. While Dierks describes the division into three layers of the vaginal epithelium as the characteristic changes, Geist mentions the changes in the thickness of the mucosa and the vacuolization in the basalis. Smith and Brunner⁷ also mention the vacuolization, which they find especially during the post-menstrual and premenstrual phase. Special attention is called to the work of Davis and Hartman,⁸ who in their

thorough investigations of a group of monkeys found the same typical cyclic changes in the vaginal epithelium as Dierks described for the human vaginal mucosa.

It would be of great importance for clinical and scientific research if a definite unmistakable "test object" were available to prove the presence of hormone activity. In human beings, one must essentially resort to the examination of the uterine mucosa. Although the removal of a piece of uterine mucosa is easily accomplished with our method on an ambulant patient (described later), it would be much simpler if one could use a strip of the vaginal mucosa for the test object. Since, according to the work of the aforementioned investigators, it seemed that the vaginal mucosa undergoes the same cyclic changes as the uterine mucosa and that it could as well be correlated with the ovarian activity, we tried to use the vaginal mucosa as an indicator for ovarian function. During our investigations we noticed that the changes of the vaginal mucosa are in no way comparable to the changes in the uterine mucosa. We could not be convinced—to say it beforehand—that any characteristic or specific changes occur in the vaginal mucosa during the various phases of the menstrual cycle. When we tried independently to examine the vaginal mucosa in order to determine its menstrual phase, we would always come to different conclusions. It was impossible to recognize from the histologic picture of the mucosa either the day or the phase of the menstrual cycle. Since with our method we could easily and without pain remove strips of the vaginal epithelium, we could also examine different parts of the vaginal mucosa of the same patient, for example, to the right and left near the portio at the same level, or at different levels near the portio and near the introitus vaginae. The results were that the vaginal mucosa of the different parts showed different histologic pictures, so that for instance in the same strip in one place the division into three layers is discernible while in another place it is absent (figs 1 and 2).

METHOD

The material on which the investigations have been based heretofore were obtained through biopsies, which occurred mostly during operations. Therefore it was possible to get from each patient a specimen of only one phase of the cycle. We used a simple method which the senior author is using for ambulatory examinations of the uterine mucosa. By means of a small very sharp and, in front curved curet, which was constructed for this purpose, a smear of the vaginal mucosa is made under pressure. Thus a strip of about 2 cm in length and about 2 mm in width can be easily removed. This is done without even local anesthesia and is absolutely painless. This procedure may be repeated as often as is necessary, so that it is possible to study without any difficulty the entire menstrual cycle on the same woman.

From the Gynecologic and Obstetric Department of the Rothschild Hadassah Hospital Jerusalem. The experiments have been carried out with the support of the Rockefeller Foundation.

We have been using a modified staining method of Papanicolaou in order that the cornification of the cells of the vaginal mucosa may be better discernible. The specimen was first stained with the hematoxylin-eosin method and, following it, counterstained with water-blue.

The following serve as our criteria:

- 1. The number of cell layers in the basalis.
- 2. The number of cell layers in the functionalis.
- 3. The presence of vacuolated cells in the functionalis.
- 4. Division of the mucosa into three layers: basalis, functionalis and the intra-epithelial zone of Dierks.
- 5. Degree of intra-epithelial cornification.

The results of observations on the various days of the cycle are seen in the accompanying tables.

TABLE 1—Vaginal Mucosa of Various Phases of Normally Menstruating Women

Case	Menstruation	Number of Cell Layers of Basalis	Number of Cell Layers of Functionalis	Vacuolated Cells	Three Layers	Cornification
1 (a)	1st day	8-10	12-16	++	—	±
2	5th day	6-9	10-16	+	—	+
3	6th day	4-8	10-12	++	—	±
4	8th day	4-7	16-18	++	—	—
5	10th day	5-7	14-18	++	—	—
6	10th day	7-13	6-8	++	+	±
7	10th day	3-6	10-12	++	—	+
8	10th day	7-11	10-12	—	±	+
1 (b)	11th day	4-7	14-20	+	++	+
9	13th day	7-9	16-20	+	+	+
10	14th day	2-3	20-24	+++	—	±
11	15th day	4-6	18-22	+++	—	±
12	17th day	4-8	18-20	++	—	±
1 (c)	18th day	3-5	12-16	+++	+	++
1 (d)	21st day	10-12	14-18	+++	—	—
13	22nd day	5-7	14-18	++	—	—

Without going into detail, it should be mentioned that we found the same picture in different phases of the cycle. Thus for example we found on the twenty-second day of the cycle (case 13) in the basalis from five to seven and in the functionalis from fourteen to eighteen cell layers, many vacuolated cells in the func-

zone of Dierks, which is characteristic for the premenstrual phase. A piece of the mucosa of the same patient, which was removed from another part of the vagina, shows no intra-epithelial zone of cornification, fewer cell layers, a picture which corresponds to the postmenstrual phase. Thus is seen on the sixth day of the cycle (case 3) in the same vaginal mucosa two different pictures, the one corresponding to the premenstrual and the other corresponding to the postmenstrual phase.

AMENORRHEA

The large material of functional ovarian disturbances at our disposal in our clinic enabled us to remove a large number of vaginal strips from patients with amenorrhea. The results are summarized in table 2. The observations in cases of primary amenorrhea are of special importance. In these cases the genitals show the characteristic poor development (atrophic labia, hypoplastic uterus and atrophic uterine mucosa). On the vaginal mucosa, however, this functional disturbance of the ovaries was not noticeable. In patient 14

20	8	7-7	12-14	+	+	++	
21	1¼	7-9	16-18	±	+	++	
22	1	5-6	14-16	++	±	+	
23	5	6-8	14-16	+	+	++	
24	2	5-8	12-16	—	—	+	
25	3½	5-6	14-18	++	+	+	
26	1¼	5-9	18-20	+++	—	—	
27	2	5-7	18-20	+	—	—	
28	3	7-7	8-10	+	±	+	

a woman aged 29 who had never menstruated, we found a basalis of from five to six cell layers, a functionalis of twelve to twenty-two cell layers, numerous vacuolated cells in the functionalis (+++), and no intra-epithelial zone of cornification. Almost the same changes were seen on the seventeenth day of the cycle of a normally menstruating woman (patient 12). The cornification differed greatly in the cases of primary amenorrhea. In cases 14 and 15 it was absent, and it was present in cases 17 and 18. In cases of primary amenorrhea we were able to produce menstrual bleeding, i. e., bleeding of a proliferative and premenstrual mucosa. If we injected into a patient with primary

Fig. 1 (case 3)—Sixth day of the cycle. Mucosa near portio to the right. Note the thickness of the basalis and the intra-epithelial zone of cornification which is absent in figure 2.

functionalis, no division into three layers and no cornification. Almost the same changes were seen on the eighth day of the cycle (case 4). Figure 3 shows on the twenty-second day of the cycle no sign in the vaginal mucosa which should be characteristic for the changes of the premenstrual phase. Figures 1 and 2, the mucosa of the sixth day of the cycle (case 3), on the other hand shows in one place an intra-epithelial

amenorrhea from 300,000 to 400,000 mouse (international units) of estrogenic substance⁹ during twenty days, bleeding out of a proliferative uterine mucosa usually occurred a few days later. If following the injection of estrogenic substance the patient is further treated with 40 rabbit units (Clausberg units) of progesterin for from five to six days, bleeding occurs out of a premenstrual mucosa from two to three days after cessation of the treatment, which is generally known. The uterus shows a measurable increase in size up to normal. Hence an atrophic uterus in a patient with primary amenorrhea can be brought to good function, the uterus can be stimulated generatively and vegetatively, but characteristic changes cannot be found in the vaginal mucosa of such patients (fig 4). A glance at the uterine mucosa in such cases suffices to recognize the specific hormone effects. But on the vaginal mucosa, on the other hand, it is impossible to determine whether the specimen was removed before or after the injections.

In cases of secondary amenorrhea, we could likewise not notice on the vaginal mucosa any signs of deficiency or absence of the ovarian function, while on the uterine mucosa it was distinctly recognizable. In patient 20 (a woman, aged 30, with amenorrhea of eight years' duration) a picture is seen which is described in the

Fig 3—Mucosa of the twenty second day of a normally menstruating woman

literature for the premenstrual changes: a basal layer of from five to eight and a functionalis of from twelve to fourteen cell layers, division into three layers, and cornification (fig 5).

THE INFANTILE VAGINAL MUCOSA

We had the opportunity of examining the vaginal mucosa of girls aged from 4 to 8 years who suffered from acute or subacute gonorrhea. The children were treated with large doses of estrogenic substance in order to influence the gonococcal infection. (The results are reported elsewhere.) What interests us here is the appearance of the infantile vaginal mucosa and the morphologic changes brought about by the estrogenic substance. The mucosa consists of about ten to sixteen cell layers. The cells are round, are rich in protoplasm and contain dark staining nuclei. Vacant cells are absent and so are cornification and the three layered appearance. After three weeks' treatment with estrogenic substance a distinct change is noticeable. The superficial cell layers become flattened and partially vacuolized just as in a functionalis of an adult. The division into three layers is not seen. These are the only definite characteristic changes that we have noticed during our investigation. What does this result mean? It is possible to consider it as a hormone effect which causes the morphologic changes in the vaginal mucosa. But one must be cautious in this interpretation, since

similar changes have not been found in patients with amenorrhea who have been treated with estrogenic substance. One must think of a different possibility. The genital tract becomes hyperemic through the estrogenic substance, and under the effect of this hyperemia changes may occur in the infantile genital tract which are not found in the adult. It should also be mentioned that Stieve, in examining Dierks' observations

Fig 4—Primary amenorrhea. Bleeding after injection of 400,000 mouse units of estrogenic substance

found analogous changes as in the vaginal mucosa in other mucous membranes (mouth and pharynx). It is naturally impossible to remove pieces of the mucous membrane of the mouth or pharynx from a living person, and especially from a child, so that it is difficult to prove this theory.

Our results surprised us. Since the uterus and vagina are both derived—as was believed till now—from the müllerian duct, it would be expected that the two should be affected in the same manner and degree by the ovarian hormones. The explanation for these negative results may be found in the work of Koff.¹⁰ The uterus is derived in all animals from the müllerian duct. The development of the vagina is more recent and varies in different species. In man it is derived partially from the müllerian duct and partially from the urogenital sinus. In the human embryo the stimulation for the formation of the vagina begins from two sinovaginal bulbs which later fuse and form the

Fig 5—Secondary amenorrhea of eight years' duration. Thick mucosa divided into three layers with intra epithelial cornification

caudal or hymenal part of the vaginal plate. The vagina would fail to develop if these sinovaginal bulbs should be damaged. For its greater part the vagina is derived from the müllerian duct. Thus the human vagina is derived from two distinct parts." Hence it is explainable that the vagina in different species reacts

⁹ We used Dimenformon (hydroxyestrin benzoate) kindly supplied to us by Organon O.S. Holland

¹⁰ Koff, A. K. Carnegie Institution Washington pub 443 Contributions to Embryology, no 140 24 59 91 1933

differently, that in one species it may and in another it may not be subject to the cyclic influence of the ovaries

Since R Meyer¹¹ and E Vilas have shown that the sinus epithelium is replacing the disappearing müllerian epithelium in the development of the human vagina and that the müllerian ducts serve only to pave the way for the sinus epithelium one cannot even expect the human vagina to respond to hormones in the same way as does the uterus

CONCLUSIONS

1 In the human vaginal mucosa we could not find cyclic changes analogous to those of the uterine mucosa

2 The vaginal mucosa shows different microscopic pictures in different places

3 In deficient ovarian function (primary amenorrhea) is found a picture of a mucosa similar to one with good ovarian function with even the same changes as in the premenstrual phase

4 In the absence of ovarian function, by means of ovarian hormones (estrogenic substance, progestin) we could produce enlargement of the uterus a proliferative and a premenstrual uterine mucosa and menstruation, but we could not find analogous changes in the vaginal mucosa

5 In human beings the infantile vagina may be influenced by estrogenic substance, but it is not certain whether it is because of a specific hormone effect on the vaginal mucosa or on the mucous membranes in general

6 Since the vagina is developed embryologically different in different species the different reaction of the vaginal mucosa is explainable

CHRONIC CARDIAC COMPRESSION DUE TO CONSTRICTING PERICARDITIS

RELIEF BY PERICARDIOTOMY, WITH A NOTE ON THE VALUE OF THE ROENTGENKYMAGRAPH

R A GRISWOLD, MD

LOUISVILLE, KY

In the realm of practical surgery the only direct operative attacks that may be made on the central circulatory system are for the relief of cardiac compression, acute or chronic. This comprises the removal of intrapericardial fluid, the prevention of its reaccumulation (including the suture of wounds of the heart), and the resection of constricting scar. The extraction of pulmonary emboli, the direct attack on valvular lesions and attempts to increase the blood supply of the heart are still within the domain of experimental surgery.

A syndrome which has increasingly engaged the attention of clinicians, especially during the past fifteen years, is that caused by a lesion variously designated as adhesive pericarditis, Pick's disease, mediastinopericarditis, concretion pericardium, pericarditic pseudocirrhosis and a host of other terms descriptive of its pathologic anatomy. Volhard,¹ Schmieden,² White,³ Churchill⁴

and others⁵ have contributed important studies during the last ten years, but the most outstanding contributions have been those of Beck.⁶ He has crystallized the physiologic point of view in place of the older anatomic and pathologic concepts. His experimental and clinical studies have shown that compression of the heart from any cause produces the "inflow stasis" of Volhard.¹ The amount of blood entering the heart is reduced as the result of pressure on the orifices of the great veins and by restriction of diastolic expansion of the auricular and ventricular chambers. The resulting clinical manifestations differ only in the rapidity with which compression occurs and not in the cause of compression. Rapidly increasing pressure gives rise to a syndrome characterized by the clinical triad of (1) falling arterial blood pressure, (2) rising venous blood pressure and (3) a small quiet heart. Slowly developing compression exhibits the triad of (1) high venous blood pressure, (2) ascites and (3) a small quiet heart.^{6,1} In both these triads the size of the heart itself must be distinguished from that of the pericardial sac. It should be emphasized that the compressed heart cannot dilate on account of the mechanical effect of compression. Hypertrophy is likewise prevented by the obstructive action of pressure on the coronary circulation. Schmieden² especially has stressed the unpaired nutrition of the myocardium that results from compression of the heart.

When one appreciates these physiologic sequelae of cardiac compression, the diagnosis of these formerly obscure conditions is less difficult and their relief becomes a matter of carefully applied surgical attack on the cause. The recognition of cardiac compression is still so infrequent, however, that additional aids to diagnosis are of value especially such an aid as can give a positive record of the amplitude of cardiac excursion before and after treatment. Cases treated by surgery are also sufficiently rare that records may be of value in developing and evaluating the worth of operative procedures.

REPORT OF CASE

History—H B, a white youth, aged 17, an apprentice jockey, admitted to the Louisville City Hospital, Jan 17, 1935, complained of painless swelling of the abdomen which had increased progressively for three months. He had had occasional night sweats a few years before. There was no history of rheumatic fever, pneumonia or pleurisy. He had noticed excessive fatigue for about six months. Dyspnea on exertion had appeared coincident with the abdominal swelling. His weight had increased from 118 to 130 pounds (53.5 to 59 kg) but he stated that he seemed to have lost weight from the shoulders and extremities. There had been no visible jaundice and no swelling of the feet or ankles. Other symptoms included a slight cough, moderate discomfort in the upper right quadrant of the abdomen, and puffiness of the face in the morning. There had been one attack of precordial pain five days before admission. Nausea and vomiting had occurred a few times since the onset. For several weeks orthopnea had been sufficient to disturb his sleep.

Examination—Slight dusky cyanosis of the face was apparent on examination. Both external jugular veins were distended and pulsating. The sclerae were yellowish. Aside from flatness and distant breath sounds in the left base, the lung fields were normal. The heart was small and the apex beat was

Two Cardiac Compression Triads. ibid 104 714 716 (March 2) 1935

neither visible nor palpable. Heart sounds were distant but regular, and there were no adventitious sounds. The pulse rate at rest varied from 80 to 100 per minute and the blood pressure was 100 mm of mercury systolic, 70 diastolic. Broadbent's and other signs characteristic of retraction of the chest wall by extrapericardial adhesions were absent. There was slight edema of the scrotum but not of the extremities. The abdomen was distended with fluid, and 6,000 cc of this fluid was removed by paracentesis. It was transudate in nature and was sterile on culture and on guinea-pig inoculation. After paracentesis

Fig 1—Preoperative appearance of the chest. The heart is not enlarged. There is widening of the upper mediastinal shadow owing to the distended superior vena cava.

the liver was found to extend three fingerbreadths below the costal margin, and the spleen was easily palpable. Both were slightly tender. The ascites rapidly recurred weekly taps yielding 3,200 cc, 5,000 cc, 5,000 cc and 5,000 cc. Routine laboratory tests showed nothing remarkable except an icterus index of 45. Six foot roentgenograms of the chest showed the heart-chest ratio to be 12.4 cm-29.3 cm. There were calcification in the root areas and increased markings consistent with an old tuberculous process (fig 1). On fluoroscopy no motion of the ventricles could be made out. The excursion of the auricles appeared to be slightly exaggerated and a definite pulsating superior vena cava was visible. The electrocardiogram showed a small, slurred QRS complex and sufficient change in the shape of the complexes with change of position of the patient to rule out fixation of the heart in the chest. Determination of the cardiac output by the dye injection method was carried out by Dr. John Walker Moore and Dr. I. M. Kinsman. The minute volume output was 376 liters and the stroke volume output 36.9 cc. Venous pressure taken by the direct method in the right arm was 240 mm of physiologic solution of sodium chloride.

It will be noted that the conditions found in this case satisfied the requirements of the triad of chronic cardiac compression, that is, high venous pressure, ascites and small quiet heart. In addition there was decompensation out of proportion to apparent cardiac disturbance and ascites out of proportion to edema, both of which are important corroborative manifestations. The low pulse pressure, fluoroscopic observations and small slurred QRS complex were suggestive. The mobility of the heart in the chest ruled out fixation by extrapericardial adhesions, but it should be noted that chronic cardiac compression produced by scar can exist without fixation of the heart.

Diagnosis—At about this time Johnson completed the roentgenkymograph that he has described.⁸ This gave most gratifying and irrefutable evidence of the reduced amplitude of cardiac pulsation and of the throttling effect of this disease on the heart. It also supplied a graphic record that could be com-

pared with postoperative plates to demonstrate the efficacy of pericardiectomy. The roentgenkymogram taken just before operation showed absolute lateral immobility of both ventricular regions indicating a marked degree of compression (fig 2). The left auricular curve was abnormal and somewhat exaggerated. The aortic waves were greatly diminished, a result of the low pulse pressure. Since there was no lateral ventricular motion and absolute ventricular immobility would not be compatible with life, it seemed reasonable to suppose that the augmented auricular curve was produced by upward diastolic expansion of the ventricular chambers into the auricular region. This would be merely an exaggeration of the normal diastolic shift of the auriculoventricular septum.⁹

Operation—This was performed February 22 under combined procaine intercostal block and closed nitrous oxide-oxygen anesthesia. The technic in general was that which has been previously described.¹⁰ The exposed pericardium was dense white leathery and almost motionless although transmitted pulsation could be felt. When the scar was incised it was found to be from 2 to 3 mm thick and was everywhere adherent to the heart. Dissection was carried out over the left side of the heart first, following the suggestion of Schmieden,¹¹ to avoid undue dilatation of the right heart. As the dissection progressed, the heart could clearly be seen to enlarge and to bulge out of its constricting shell. Dissection was carried out until the finger could be swept completely around the heart over the auricles and ventricles. The heart could be easily lifted forward and upward to give a complete view of the intrapericardial portion of the inferior vena cava. Dissection over the auricles was by sharp knife. Over the ventricles, a combination of blunt and sharp dissection was utilized. The pericardium was excised laterally back to the region of both phrenic nerves and on the diaphragmatic aspect to within 2 cm of the vena cava. Several small openings were made into both pleural cavities but were easily compensated for by positive pressure anesthesia. These openings were closed with silk with the exception of one into the left pleura, which was enlarged to 4 cm and left open to provide drainage from the field of operation into the pleural cavity. The soft parts of the chest were closed in layers with fine silk without drainage. Hemostasis was obtained throughout by the endotherm. Pathologic exam-

Fig 2—Preoperative roentgenkymogram showing no waves over either ventricular area. This clearly indicates complete absence of lateral ventricular movement due to the choking effect of the tight inelastic pericardial scar. The exaggerated abnormal auricular waves are probably caused by the upward thrust of the ventricles into the auricular space during ventricular diastole since this is the only avenue possible for ventricular expansion. Aortic waves are diminished in consequence of low pulse pressure.

ination of the excised scar showed much scarred pericardium with residual active chronic inflammation. There was no evidence of tuberculosis.

Several points in the technic of this procedure may well be emphasized. It should be the rule in all cardiac

operations to have intratracheal or positive pressure anesthesia available to compensate for probable injury to the pleura. Dissection of the scar from the heart must be carried out with great care. Forceful blunt dissection is contraindicated, since in many instances scar and even calcium deposits may extend into the myocardium. Meticulous sharp dissection is especially

advisable over the auricles, the thin walls of which are seldom so strong as the fibrous adhesions. Blunt dissection may be most gently and safely carried out over the ventricles by allowing the rhythmic contractions of the myocardium to break the adhesions as the finger lies motionless in the angle formed by the heart and the freed portion of the myocardium. Manipulations within the pericardium cause considerable cardiac irregularity, and frequent periods of rest are necessary to restore normal

rhythm and maintain cardiac function within safe limits. Haste has no place in this operation.

The drainage of the large amount of fluid which forms about the heart after this and other cardiac operations is a serious problem.¹¹ The absorptive qualities of the mediastinal tissues are uncertain, and

seen fluid pumped in and out of such a wound with each respiratory excursion will appreciate the danger. The most satisfactory way out of this dilemma is to leave a generous opening (from 3 to 5 cm) for drainage into one of the pleurae. During the postoperative period the effusion is removed from the pleura by syringe and needle as indicated. I have been so impressed with the ease and safety of this method of drainage that it has been used by myself and Drs. J. M. Mayer¹² and E. M. Drissen (resident surgeons at Louisville City Hospital) in several heart wounds with gratifying absence of postoperative cardiac compression and infection. Usually an existing rent in the mediastinal pleura may be enlarged to the proper size.

Postoperative Course—On account of slight cyanosis, the patient was placed in an oxygen tent for the first few days as a precautionary measure. The pulse was slightly irregular

Fig 3—Postoperative roentgenogram showing practically normal cardiac mobility. There is wide amplitude of pulsation over both ventricular areas. This demonstrates adequate decompression by pericardiectomy. The auricular curves appear normal and deep aortic waves demonstrate increased pulse pressure.

enough fluid may collect within a few hours to produce serious compression of the heart. Leaving a drainage tract leading to the surface of the skin carries with it a real hazard of infection. Any one who has

for four days but the rate never exceeded 120 per minute. During the first four days a total of 1,375 cc of serosanguinous fluid was aspirated from the left pleural cavity. The preoperative cyanosis and distention of the external jugular veins disappeared completely within ten days. The wound healed without drainage or infection. Slight fever (as high as 101.4 F) about the tenth day was thought to be due to a tender swelling which appeared in the right supraclavicular region and persisted for about one week. In the light of later observations this probably was thrombosis of the right subclavian vein. The urinary output exceeded the fluid intake on the thirteenth day. No abdominal paracenteses were done after operation and by the fifteenth day, when the patient was allowed out of bed, the ascites had definitely diminished. Abdominal fluid could not be detected on the eighteenth day and has never recurred. The six foot roentgenogram of the heart showed that the cardiac shadow had increased from 12.4 cm to 13.5 cm in width. Postoperative roentgenograms (fig 3) demonstrated clearly the efficacy of the operation that freed the heart from its constricting shell. Ample ventricular excursion was apparent on both sides and the deep aortic curves indicated increased pulse

pressure Three months after operation, cardiac output determination by the dye injection method showed a minute volume output of 790 liters and a stroke volume output of 888 cc more than double the preoperative output At this time an unduly high (255 mm) venous pressure reading led to the discovery that there was thrombosis of the veins draining the right upper extremity Venous pressure in the left arm was 75 mm of physiologic solution of sodium chloride The electrocardiogram at this time again showed sufficient change in the shape of the complexes to rule out fixation of the heart in the chest The QRS complex in lead I was small and slightly inverted Leads 2 and 3 were negative The pulse rate was 90 per minute and the blood pressure 112 mm of mercury systolic, 74 diastolic Six months after operation the pulse rate was 100 per minute the blood pressure 108 mm of mercury systolic 50 diastolic, and the venous pressure 60 mm of physiologic solution of sodium chloride Nine months after operation the patient was normal in every way except for slight tachycardia There had been no recurrence of ascites dyspnea or other cardiac symptoms and he was working regularly as a tobacco grader

At present one year after operation the patient has returned to his occupation as a jockey and has been training and exercising thoroughbreds for the past two months without cardiac symptoms This is extremely strenuous exercise

SUMMARY

1 In a patient with chronic cardiac compression caused by scar (the Pick syndrome) complete relief was obtained by resection of the constricting scar

2 The roentgenokymogram is of value both as a positive diagnostic measure and as evidence of the efficacy of pericardiectomy

3 There are advantages of decompression of the heart during the postoperative period by drainage into the pleura

PONTILE ABSCESS

REPORT OF TWO CASES

BEN W LICHTENSTEIN MD

AND

HOWARD ZEITLIN, MD

CHICAGO

The occurrence of abscesses in the pons is, like that in the medulla and spinal cord rare when compared with the incidence of abscesses elsewhere in the central nervous system¹ Thus, Gowers² found among 231 cases of brain abscess only three in the pons, and, according to Cassirer, LeFort and Lehmann³ found only six cases among 458 Among the forty-five cases of brain abscess in a series of 7349 necropsies at the Cook County Hospital⁴ from Jan 1, 1929, to July 1, 1935, only two were in the pons The distribution of the forty-five cases is given in table 1 The etiology of the types present is distinguished in table 2

The vascular supply and location of the pons probably explain its relative immunity to abscess formation Since emboli usually enter the brain by way of the carotid arteries, metastatic abscesses can only seldom reach the pons, as the latter gets its blood supply from a different source—the basilar and vertebral arteries Its location in the posterior cranial fossa removed from

the more common sources of cerebral infection (compound skull fractures, sinusitis, otitis, mastoiditis) explains the infrequent spread of infection into the pons

The clinical picture of pontile abscess is markedly polymorphous In the majority of cases it is that of hemiplegia alternans inferior Also known as the Millard-Gubler syndrome, it is characterized by an ipsi-

lateral paralysis of the face and a contralateral hemiplegia This syndrome denotes a lesion in the basilar portion of the pons The much rarer type is that of Foville, which was present in our first case

REPORT OF CASES

CASE 1—History—F E, a white man aged 65, admitted to the neurologic ward of the Cook County Hospital May 8, 1935, complained of headache of two weeks' duration which was so severe that he was forced to go to bed The day following the onset he noticed that he could not close his right eye and that there was numbness over the left side of the body Difficulty in speaking and swallowing gradually developed At the time of admission to the hospital he could no longer walk He had had gonorrhea and the usual diseases of childhood He was married his wife was living and well and he had no children

Examination—The patient was fairly well developed and did not appear acutely ill The temperature was 99.2 F, the pulse rate was 112 and the respiration rate was 26 The blood pressure was 150 systolic and 90 diastolic The heart tones were distinct and there were fine crepitant rales throughout the bases of both lungs posteriorly The abdominal organs were essentially normal The patient could neither close his right eye nor wrinkle the right side of his forehead The right nasolabial fold was obliterated The right pupil was dilated and the right eyeball could not be moved outward The conjunctiva of the right eye was severely injected and there was an opacity of the cornea The left eyeball could be moved in all directions and the pupil reacted well to light and in accommodation The right side of the pharynx was relaxed and the tongue deviated to the right when protruded There was difficulty in hearing and speaking with diminution of the sensations of pain and touch over the left arm and leg and the left side of the abdomen Deep sensibility and the sense of position in the left extremities were intact There was a marked paresis of the left upper and lower extremities The deep tendon reflexes were present and equal bilaterally Babinski and Rossolimo signs were absent

Laboratory Examination—Spinal puncture revealed clear fluid under normal pressure The Pandy reaction was 2+ and there were 8 cells per cubic millimeter The blood and spinal fluid Wassermann reactions were negative The urine was normal

Course—The patient's condition rapidly grew worse On attempting to swallow he would choke and fluids would regurgitate through his nose The cornea of the right eye became

more severely inflamed and superficial erosions developed. These were treated by a 1 per cent solution of atropine, which was instilled into the conjunctival sac, and the eye was kept protected with a shield. Crepitant rales developed in both lower pulmonary lobes and by May 14 bronchopneumonia set in. During all this time the condition was so critical that a detailed examination of the sensibility could not be made.

Fig 1 (case 1)—A pontile abscess of the base with invasion of the tegmentum

The patient died, May 14 six days after entrance into the hospital and approximately three weeks after the onset of his illness. The diagnosis was some destructive lesion probably a hemorrhage, in the right side of the pons varoli.

Necropsy (Dr R. H. Jaffe)—The anatomic diagnosis was abscess in the right side of the pons, confluent bronchopneumonia in all pulmonary lobes, anemia and parenchymatous degeneration of the liver and the kidneys, parenchymatous degeneration and atrophy of the myocardium, hypertrophy of the prostate gland, polyp of the transverse colon, atrophy and infectious softening of the spleen, iridocyclitis of the right eye.

Macroscopic Observations. The essential changes were found in the brain. It weighed 1550 Gm. The leptomeninges over the cerebral hemispheres were slightly thickened and injected. The vessels at the base of the brain were thin walled and patent. The pons, especially on the right side, was enlarged, very soft and swollen. It measured 5 cm in transverse diameter and 4 cm in anteroposterior diameter. In the right brachium pontis there was a 14 by 10 mm area of light purplish brown discoloration. The brain was sectioned after it had been fixed in a 10 per cent solution of formaldehyde. On the right side of the pons, extending for 7 mm from the left of the midline, there was an oval cavity 25 by 20 mm in diameter which was filled with thick, light yellowish green pus and was lined by a light purplish brown membrane about 0.5 mm thick (fig 1). The lateral ventricles were distinctly dilated and the ependyma was smooth. The cortex and basal ganglia were light purplish brown. Other gross pathologic examinations disclosed that the middle ears and nasal sinuses were not affected and that the right eyelid was closed by dried pus. The cornea was cloudy and the pupil irregular in shape.

Microscopic Observations. The abscess in the region of the pons was separated from the brain parenchyma by a poorly developed young connective tissue capsule. The capsule consisted of three fairly distinct layers (fig 2). The innermost, adjacent to the pus, was composed of dense masses of gitter cells, the contents of which stained with sudan III. In sections stained by van Gieson's method there were discerned among and above these cells swollen fibrocytes mixed with fine purplish pink stained connective tissue fibers. This layer also contained polymorphonuclear leukocytes and some plasma cells. In the middle layer the most predominant features were dilated blood vessels and capillaries surrounded by a loose network of swollen fibrocytes, young connective tissue fibers and a few histiocytes.

plasma cells and gitter cells. The endothelial cells of the capillaries were swollen. The outer layer, bordering the cerebral parenchyma, was formed by somewhat denser connective tissue fibers and swollen fibrocytes. The latter layer likewise contained numerous plasma cells, macrophages and gitter cells. The lumen of the abscess was filled with debris of degenerated polymorphonuclear leukocytes and small lymphocytes. In Gram-Weigert stained sections, clumps of gram positive diplococci and short chained streptococci were seen in the necrotic material. The brain parenchyma in the vicinity of the abscess capsule appeared fairly normal, except for the congested blood vessels, which showed a marked proliferation of their adventitial layers and widening of their Virchow-Robin spaces (fig 2). These spaces were packed with large numbers of plasma cells. The ganglion cells, except for slight evidence of chromatolysis, were unchanged. There were no proliferative or degenerative changes in the glial elements. Perivascular infiltrations were confined to the brain tissue—in the immediate vicinity of the abscess—as the lower medulla oblongata and the brain stem in the region of the cerebral peduncles failed to show such changes.

The subarachnoid space, particularly at the base of the brain, was widened and infiltrated with numerous lymphocytes, plasma cells, macrophages and a few gitter cells (fig 3). The pial blood vessels were proliferated, their endothelial as well as adventitial cells were prominent. The epineurial and perineurial spaces about the cranial nerves, at the base of the brain, revealed a moderate cellular infiltration. The nerve roots themselves were essentially normal. The choroid plexus contained numerous small calcium concretions but was essentially normal.

A case of tegmental pontile abscess presented a syndrome of the Foville type: paralysis of the sixth and seventh nerves on the right side with contralateral hemiplegia and dissociated hemianesthesia. Of considerable interest was the presence of keratitis on the right side, in addition to the disturbances of sensibility. The Foville syndrome is rare and, as this and other

Fig 2 (case 1)—The upper half of the section contains the infiltrated blood vessels (D) in the brain tissue which is separated from the abscess (A) below by a capsule. B, zone of gitter cells. cases show denotes a tegmental lesion of the pons. Rare as such cases of pontile lesion are, those in which the clinical picture is that of a cerebral involvement, as in case 2, are still rarer.

CASE 2—History.—M. K., a white boy, aged 12 years, admitted to the Children's surgical ward of the Cook County Hospital July 1, 1932, was in deep coma and his father stated

that the boy had had a discharging right ear for two and one-half months, severe headache and projectile vomiting for six weeks, paralysis of the left arm and leg for five weeks, and incontinence for three weeks. The complaints dated back to April 14, when the boy noticed a purulent discharge from the right ear. The ear drum was incised and drainage was good for a few days, after which it suddenly stopped. A septic temperature developed (from 101 to 102 F). In May the right mastoid was operated on but the headaches continued and were accompanied by projectile vomiting. The ear was opened a second time and, June 6, the right temporal region was operated on as a brain abscess was suspected. The operation did not improve the patient's condition, he was unable to feed himself and in the last week he had difficulty in swallowing.

The past history revealed that the patient had a tonsillectomy and adenoidectomy in 1928 and a radical mastoid operation (on the left side) in 1929.

Examination—The temperature was 101.8 F, the pulse rate was 94 and the respiration rate 32. A bandage covered the right side of the head. When removed, a linear wound was seen in the right temporal region. The wound was gaping and exuded a yellowish purulent material. Behind the right ear over the mastoid, was a linear depression 1.5 cm in depth and 1½ inches (3.8 cm) in length. The conjunctiva of the right eye was injected, and purulent material was present on the inner canthus. The pupils were equal and reacted to light. A yellowish purulent material exuded from the right ear. There were excoriations and herpes on the lips and the mouth was filled with thick, greenish white, purulent material. The left side of the chest lagged during respirations; it was dull to percussion, especially in its lower portions posteriorly. The breath sounds were harsh, with numerous moist rales. Examination of the heart and lungs was negative. There was a spastic paralysis of the left arm and leg with exaggeration of the biceps, triceps, patellar and achilles reflexes. There was a positive Babinski sign on the left side.

Laboratory Examination—A spinal puncture revealed a clear cerebrospinal fluid under normal pressure. The Pandy test was positive and there were 10 lymphocytes per cubic millimeter.

Course—The child died six and one-half hours after admission.

Necropsy (Dr R. H. Jaffe)—The anatomic diagnosis was abscess in the right half of the pons extending into the right brachium pontis with marked peripheral inflammatory reaction, edema of the brain and acute internal hydrocephalus. Radical operation of the right middle ear, mucopurulent otitis media of the right side, ancient thrombosis of the right lateral sinus of the dura mater, a trephine wound in the right temporal region with exposure of the sylvian fissure, bronchopneumonia in both lower and upper pulmonary lobes, suppurative tracheitis and bronchitis, subacute infectious softening of the spleen, parenchymatous degeneration of the myocardium with dilatation of the left ventricle and endocardial sclerosis and cloudy swelling of the kidneys.

Macroscopic Observations The essential changes were found in the head. In the right temporal region was an oval defect 3.5 cm long and 2 cm wide. The edges were dry and the floor exposed purplish gray, firm tissue. Behind the right ear was a 3 by 1 cm surgical wound extending to the bone. In the region of the defect in the right temporal region the dura mater was exposed and presented a 7 mm opening. The external surface of the dura about the opening was thickened and fibrotic. The internal surface was smooth. The right temporal lobe was loosely adherent to the dura in this region, and in the right temporal bone there was a 20 by 12 mm defect which was closed by a thin membrane. The external surface of the dura mater in this region was covered by an adherent firm light yellow membrane 4 mm in thickness.

The right lateral sinus was transformed into a firm dark purple red cord. The right middle ear was filled with a yellowish gray mucopurulent material. The left middle ear was unchanged.

The brain was greatly swollen, the leptomeninges were injected and the convolutions flattened. In the right sylvian fissure there was a 10 mm shallow defect. The right half of the pons was swollen measuring 5 by 4.5 by 2.5 cm in diameter. The swelling extended into the right brachium pontis. After having been fixed in formaldehyde the brain

was sectioned, and in the region of the base of the pons there was a roughly spherical mass 4 cm in diameter, containing a semiliquid mucopurulent material. It occupied the greater part of the right side of the pons and extended into the right brachium pontis. It was surrounded by a 1 mm purple-gray zone.

The ventricles were dilated and filled with an excessive amount of fluid. The brain substance including the basal ganglia was moist and light purple gray.

Microscopic Observations The abscess in the pons was surrounded by a fairly well developed connective tissue capsule. The innermost layer of the capsule was formed by fibroblasts and histiocytes and was infiltrated with numerous polymorphonuclear leukocytes and gutter cells. The outermost layer bordering on the brain parenchyma was also formed by dense masses of swollen fibroblasts and young connective tissue fibers among which were many plasma cells and histiocytes. Between the foregoing (external and internal) layers were numerous newly formed capillaries with markedly swollen endothelial cells. Surrounding these capillaries and extending about in

Fig. 3 (case 1)—Aseptic meningitis. M marked infiltrations of the meninges. P Purkinje cells. Toluidine blue satm. $\times 100$.

the form of a loose network were numerous proliferating and swollen fibroblasts, histiocytes and fairly dense accumulations of plasma cells which varied in size. Their cytoplasm was often in the form of an elongated body and occasionally contained two nuclei. Within the abscess were numerous small, homogeneous spherical bodies that stained pale blue with hematoxylin. In addition there were single well preserved pus cells and histiocytes. The brain tissue about the capsule was loosened and edematous. The Virchow-Robin spaces of the blood vessels were markedly dilated and filled with plasma cells.

The ganglion cells showed slight chromatolysis. The nerve fibers and glial elements showed no abnormal changes.

The right lateral sinus was covered within by a layer of coagulated blood into which young capillaries extended from the wall. The wall itself was unchanged.

Bacterioscopic examination of smears from the pontile abscess revealed numerous degenerated polymorphonuclear leukocytes and much cellular debris in which a few gram positive cocci were arranged in pairs and in short chains.

This case of pontile abscess thus showed clinically only a contralateral hemiplegia. It so much resembled

a cerebral lesion that the cortex was explored surgically. The location of the abscess in the pons was such that it precluded additional involvement of a cranial nerve, which is so essential in a correct diagnosis of a pontile lesion.

SUMMARY AND COMMENT

In both cases the abscess possessed a young connective tissue capsule and was associated with a nonsuppurative encephalitis in its immediate vicinity, mild degenerative ganglion cell changes and a marked meningitis.

Pathology—In our cases, the histopathologic changes of the poorly developed capsule surrounding the abscess, together with the changes in the adjacent brain tissue and the reactive phenomena in the subarachnoid space, were very similar to those previously reported by Kolpin,⁵ by Diamond and Bassoe⁶ and particularly by Hassin.⁷ The elements participating in the formation of the capsule were exclusively mesodermal. Although the capsule was immature, its differentiation into three layers was fairly evident. The inner layer was formed by dense swollen fibroblasts, occasional young connective tissue fibers and numerous gutter cells, macrophages, polymorphonuclear leukocytes and plasma cells. The middle layer contained numerous capillaries surrounded by fibroblasts, histiocytes, plasma cells and gutter cells. In the outer layer the fibroblasts were denser, with numerous young connective tissue fibers. Polymorphonuclear leukocytes were absent in the outer layer. The brain tissue about the abscess wall contained numerous blood vessels at a short distance above and below the abscess, their adventitial coats swollen and thickened and their perivascular spaces (Virchow-Robin) markedly infiltrated with plasma cells. The latter changes corresponded with those described as nonsuppurative encephalitis.

The increased cellularity found in the dilated subarachnoid space at the base of the brain is of particular interest and of great clinical significance.

The meningeal reaction following an aseptic irritation as exhibited by the presence of lymphocytes, macrophages, plasma cells and fibroblasts in the subarachnoid space was first termed by Ayer⁸ "aseptic meningitis." These changes are also similar to those produced experimentally by Weed⁹ and Essick,¹⁰ who injected laked blood and lamp black into the subarachnoid space. Hassin¹¹ likewise showed similar reactive changes in a case of acute manic state. In our case the presence in the subarachnoid space of gutter cells and the catabolic products in connection with the brain abscess were undoubtedly instrumental in producing these reactive phenomena. The experimental work of Weed, Forster¹² and others as well as the facts from human pathology¹³ conclusively proved that the flow of tissue fluid is from the Virchow-Robin spaces to the subarachnoid spaces

of the brain and cord. Carrying the gutter cells and waste substances into the subarachnoid space causes a reactive phenomenon in the meninges, which is known as aseptic meningitis.

Clinical and Anatomic Considerations—Some cases that have been reported in the literature as abscess in the pons were really those of tuberculoma (Abercrombie,¹⁴ Wendt¹⁵ and Tuley¹⁶). Other cases were metastatic pyogenic abscesses (H. Bercher,¹⁷ Cassirer,¹⁸ Bregman,¹⁸ Pollak¹⁹) or had an altogether doubtful and indefinite etiology (Forget,¹⁷ Meynert,¹⁷ May,²⁰ Pitt,²¹ Lorenz²²). Concerning the etiology of the abscess in our first case there are several possibilities, since a detailed history was not available. If the infection of the eye can be considered primary, the abscess can be readily explained as a metastatic lesion. Direct extension from the eye to the pons may have occurred in analogy to the mode of spread of an encephalitic virus to the brain after inoculation²³ into the cornea. On the other hand, the conjunctivitis may have developed when the pontile abscess became large enough to involve first the seventh nerve, making it impossible to close the right eye completely, and later the nucleus of the trigeminal nerve on the right side, producing corneal anesthesia. The latter sequence of events was present in the pontile abscess reported by Cassirer.

The presence of pleocytosis in the cerebrospinal fluid in cases of brain abscess is self explanatory when one considers our discussion about aseptic meningitis. Woltman²⁴ has utilized the number of cells in the cerebrospinal fluid as an index of the degree of encapsulation (the fewer cells, the more mature the capsule). He also utilized the nature of the cells in determining whether the abscess was in the process of extension or was approaching the meninges or the ventricles. In these two conditions an appreciable number of neutrophilic leukocytes appeared.

A comparison of the cellular reaction in the subarachnoid space in a case of an eight year old abscess, as reported by Hassin,⁷ with the cellular reaction in our case (a young abscess) readily illustrates that the number of cells decreases the more localized and encapsulated the abscess is.

CONCLUSIONS

1 Pontile abscesses produce variable clinical pictures, depending on their localization.

2 The direction of the discharge of tissue fluids and toxic products from the region of the abscess into the subarachnoid space was indicated by the reactive phenomena about the perivascular spaces surrounding the abscess—nonsuppurative encephalitis—and the resulting secondary meningeal reactive changes—aseptic meningitis.

TRANSMISSION OF SYPHILIS BY
BLOOD TRANSFUSION

A CASE OF ACUTE GUMMATOUS OSTEOMYELITIS

HARRY MANDELBAUM, MD

BROOKLYN
AND

ABRAHAM N SAPERSTEIN, MD

BELLEROSF, N Y

One of the hazards of blood transfusion is the transmission of syphilis by this procedure. The first known case of syphilis thus acquired was Dade's, reported by Fordyce¹ in 1915. Morgan² collected a total of sixteen cases, including one of his own. Jones and his associates³ recently reported another case of "transfusion syphilis."

Hazen⁴ asserts that it is not improbable that 10 per cent of the adult male population of the United States is definitely syphilitic. In view of the wide popularity that blood transfusion enjoys in the practice of medicine today, it is fortunate that syphilis is not transmitted more frequently. This has been explained by Morgan² in his recent article. 1. There is considerable evidence to substantiate the view that blood from a donor with inactive (chronic) syphilis fails to transmit the disease to the recipient. 2. Brown and Pearce⁶ in experimental syphilis in rabbits have shown that spirochetes are present in the blood during the acute or active phase of the infection. With the disappearance of the active lesions, the spirochetes are no longer present in the blood and the blood loses its capacity to infect. Ebersson and Engman⁷ have proved that in latent syphilis the reservoir for *Spirochaeta pallida* is chiefly lymphoid tissue and not the blood. Of the sixteen cases analyzed by Morgan,² the status of the syphilitic infection in the donors could be determined in eleven. Of these, ten presented acute primary or secondary syphilis, and the eleventh chronic syphilis complicating pregnancy. The virus has been shown to be present in the blood during pregnancy.

The cases that have been reported of syphilis acquired through the medium of blood transfusion have all shown the picture of a generalized secondary stage of the disease within one to three and one-half months after the transfusion.

The following case of "transfusion syphilis" is of especial interest. The initial manifestation of syphilis was an acute gummatous osteomyelitis. It is the first recorded instance of syphilis so acquired in which no evident secondary stage was present.

REPORT OF CASE

History—L. S., a white woman, aged 29, admitted to the Jewish Hospital, May 30, 1934, complained of headache of three weeks duration. She had measles, whooping cough and mumps as a child; the tonsils and adenoids were removed in 1926. Her parents were alive and well and, as far as she knew, her two brothers were in good health. Catamenia was for five days at intervals of twenty-eight days.

She was married in 1931 and became pregnant a year later. Toward the latter months of pregnancy albuminuria, hypertension and headaches developed. Placenta praevia complicated the labor and a stillborn child was delivered by forceps. During her second pregnancy she felt well, albuminuria or hypertension did not develop. At term, after thirty-two hours of labor, a preoperative transfusion was given and twins were delivered by cesarean section, Feb. 2, 1934. Her brother acted as the donor. Her convalescence was uneventful.

April 1, 1934, eight weeks after delivery, she complained of pain in the chest and both shoulders. The pain became so intense that morphine was required for relief. Within forty-eight hours a tender swelling, the size of an olive, appeared over the middle of the sternum. The pain and swelling continued unchanged for several days and then gradually abated, a residual soreness persisting. Four weeks later (May 1) she

Fig. 1—Roentgen appearance of skull showing areas of rarefaction.

complained of intense pain over the entire skull. Within a few days a hard tender swelling, the size of an olive, appeared on each side of the forehead. Both eyes appeared to be protruding. The tumors and headache persisted for a week and then gradually subsided, leaving a residual soreness. A week before admission (May 23) intense pain preceded by twenty-four hours the appearance of three small nodules, one over the left parietal region and two over the middle of the forehead.

The patient positively did not show by symptoms and/or signs of the presence of any antecedent skin or mucous membrane lesions.

Physical Examination—The patient was of average well proportioned development. Palpation of the skull revealed points of tenderness conforming to her localization of previous swellings. Three small subcutaneous swellings, each the size of a dime (18 mm) were noted: one on the forehead just above the nose, a second directly above this at the hairline, and a third over the left parietal region. The nodules were well circumscribed, exquisitely tender and soft and appeared to be attached to the underlying bone. The skin over the nodules was not attached. The pupils were equal and reacted to light and in accommodation; consensual reflexes were present. The nasal margin of the right disk was blurred, the left disk was blurred and appeared slightly raised. No hemorrhages or exudates were seen.

The sternum showed a point of tenderness over the lower end of the gladiolus. Palpation of other bones revealed nothing of note.

The heart and lungs were normal. The abdominal organs could not be palpated. Neurologic survey revealed no additional pathologic changes.

The impression was that this case was probably one of gummatous periosteal tumefactions involving the skull and sternum.

Fig 2—Roentgen appearance of skull showing areas of rarefaction

Course in the Hospital—Three days after admission (June 2) the patient complained of intense pain over the right frontal region. The pain was worse the next day, and a swelling the size of a small olive appeared over the right side of the forehead. It was well circumscribed and was attached to the underlying bone, and the skin over it was freely movable. The headache and swelling persisted for five days and then gradually subsided. The temperature and pulse were normal throughout her stay in the hospital.

Laboratory Examinations—The blood Wassermann and Kahn tests, May 31 and June 2, were four plus.

June 2, 20 cc of clear spinal fluid was removed under 100 mm of water pressure. The Queckenstedt test was negative. No cells were noted. Reducing substance was 55 mg per hundred cubic centimeters. The Wassermann reaction was negative. There was no reduction of colloidal gold. Bacteriologic study gave negative results.

The urine, examined several times, showed no albumin, sugar or pathologic cellular elements. In the concentration test the volume excreted ranged from 130 to 280 cc, the specific gravity ranged from 1.010 to 1.020. Chemical examination of the blood, June 1, revealed sugar, 117 mg per hundred cubic centimeters, urea 11 mg, creatinine 1.5 mg, uric acid, 62 mg, carbon dioxide combining power, 52.6 volumes per cent, calcium 10.4 mg per hundred cubic centimeters, phosphorus 4 mg.

A blood count showed red blood cells 4,800,000, white blood cells 6,800, with polymorphonuclear leukocytes 54 per cent, lymphocytes 46 per cent and hemoglobin 65 per cent (Sahli).

The basal metabolic rate was 0.

An electrocardiogram was within normal limits.

Roentgen Examinations—The cardiac shadow was within normal limits and the aortic shadow was normal. The lungs showed no pathologic changes.

Over the left parietal region of the skull and over the middle of the frontal bone irregular areas of rarefaction were present. The diagnosis was gummatous infiltration (figs 1 and 2).

Roentgenograms of the sternum showed an area of rarefaction of the lower end of the gladiolus. The diagnosis was gummatous infiltration (fig 3). The pelvis showed no pathologic changes and both the right and left tibias were normal.

Subsequent Course—Treatment with bismuth compounds, iodides and arsphenamine was instituted in the hospital and was continued by one of us (A. N. S.) after her discharge from the hospital, June 18. A spinal tap was again done October 16, no pathologic changes were noted. The blood Wassermann and

Kahn tests were reported negative, Oct 16, 1934, and plus minus, Sept 10, 1935. Roentgen examination on September 11 showed that the areas of rarefaction previously reported had been completely filled in.

Blood Wassermann and Kahn tests were done on the twins and the patient's husband and were reported negative, Aug 1, 1934, and Sept 10, 1935. The donor, the patient's brother, was examined as soon as the diagnosis was established. There was no evidence of primary or secondary syphilis. Blood Wassermann and Kahn tests were reported four plus on June 20, 1934 and Sept 10, 1935.

COMMENT

The patient was intelligent and cooperative. She was positive in her assertion that neither symptoms nor signs suggestive of secondary syphilis preceded the onset of her illness, nor could she recall anything pertinent in her past history. It is an accepted fact that latent syphilis can be reactivated by pregnancy. Schamberg and Wright⁸ state that every woman who has had active syphilis before or during pregnancy, and who has received no treatment or inadequate treatment, is liable to give birth to a syphilitic child, infection taking place through the placenta. Almkvist⁹ reports that in twenty-seven of twenty-eight infants born to syphilitic mothers, the disease became manifest in from fifteen days to eight months after birth. Thus the absence of signs of syphilis in the twins and the negative Wassermann reactions on their blood may be interpreted as evidence that the disease was not present in the mother during her pregnancy.

The patient's brother, who had acted as donor, admitted that he was exposed to syphilis in 1930, when he had been living with a woman who had syphilis. A Wassermann test was done at that time and was reported negative. He stated that there had not been any primary or secondary manifestations of syphilis.

He was examined immediately after the diagnosis was established (June 1934) and several times later, and no lesions indicative of syphilis were discernible. Blood Wassermann and Kahn tests were reported positive, June 20, 1934, and Sept 10, 1935.

Syphilis of the bone may occur early as well as late in the disease. According to Schamberg and Wright⁸ the spirochete early in the course of syphilis tends to invade the bone marrow. The specific gummatous foci appear most frequently in the periosteum.¹⁰ The gummatous overgrowth follows the vessels as they enter the skull into the bones from the periosteum. When the bone is involved as well as the periosteum, Kaufmann describes the lesion as "acute gummatous osteomyelitis."¹⁰ The

roof of the skull the sternum, the phalanges and the tibiae are most frequently involved

This patient thus represents a case in which acute gummatous osteomyelitis was the initial lesion of syphilis transmitted by a blood transfusion

SUMMARY

1 In a case of acute gummatous osteomyelitis, syphilis was acquired through the medium of a blood transfusion. There was no evidence of the secondary manifestations of syphilis

2 The blood donor was not in the active phase of syphilis at the time of the transfusion, nor has he subsequently shown active lesions. Blood Wassermann and Kahn tests have repeatedly been reported positive

COCCIC INFECTIONS OF THE RENAL CORTEX

EDWIN BEER, M.D.

NEW YORK

It is surprisingly strange how slowly the medical profession is coming to appreciate the importance of cortical kidney infection due to the various types of cocci, as well as the various clinical pictures of this condition and its very definite relation to perinephritis, to perinephric abscess and probably to chronic sclerosing perinephritis. In this paper I shall analyze some of my observations, which I have attempted to describe in part previously and which corroborate much that is scattered here and there in the literature

Though the clinical picture presented by these cortical coccic infections in previously normal kidneys may vary from the most acute disease to a more or less chronic one, usually the diagnosis can be made and proper therapy instituted before irreparable harm to the kidney or to the patient is done. There is a distinct and definite difference between these cases and the bacillary infections: colon, proteus, pyocyanus, Friedlander, and so on.¹ Pyuria is a characteristic of these cases, while in the coccic cortical abscesses the urine is usually clear. In the literature, unfortunately, the two types are frequently combined and described together, making for great confusion. Rarely coccic infections and bacillary infections occur together and make the diagnosis much more difficult. However, such cortical infection, whether coccic or bacillary, is usually superimposed on a previously diseased kidney, infected hydronephrosis, pyonephrosis or calculous pyelonephritis and more rarely on tuberculosis and on polycystic or neoplastic disease. This type of cortical abscess, as opposed to the metastatic coccic abscesses in previously healthy kidneys, only occasionally leads to suppuration in the so called perinephrium

It seems to me that too much emphasis has been placed on the peracute, fulminating unilateral, septic hematogenous infections, which in my experience have been encountered infrequently compared with the acute embolic abscesses, which also are often associated with positive blood cultures. The former group are often a part of a general, overwhelming sepsis and though the symptoms may be unilateral, both kidneys, the lungs and other organs frequently show embolic abscesses. If symptoms and signs are limited to one side, early

removal of the diseased kidney may effect a cure, whereas in the other group primary nephrectomy is rarely indicated. At the opposite end of the scale, there may be a mild and very transitory group with fever, pain and tenderness lasting a short time in which cocci have been found on smears from the centrifugated urine (Crabtree,³ Cabot,⁴ Nesbit⁵). These cases are still *sub judice* and may belong to the group of non-suppurating, diffuse staphylococcic nephritis. "Almost all patients recover, usually undiagnosed."⁶ Between these two extremes there is a large group of cases of cortical abscess and cortical carbuncle, which rarely get well without incision, drainage and decapsulation or nephrectomy, and which underlie almost all cases of perinephritic suppuration

Cortical abscess of coccic origin, not caused by direct injury, is always secondary or perhaps tertiary to a focus of infection or abrasion, perhaps weeks or months earlier and often forgotten by the patient. The infection may be in the skin (furuncle, abscess, carbuncle, paronychia, infected wounds, abscess of prostate or testes, erysipelas) or a gum boil or infected tooth and rarely to a systemic infection without or with evident skin suppuration. It may also be due to subacute or chronic osteomyelitis or to an infection of the upper respiratory tract, including tonsillitis

There has always been a certain amount of mystery as to how the coccic emboli or the microscopic mass of cocci arrive at the kidney and lodge in the small end arteries. Whether they traverse a patent foramen ovale (a not uncommon anatomic defect) and thus reach the left side of the heart or whether they are small enough to traverse the pulmonary capillaries has always been conjectural. The only thing that is certain from clinical observation is that the coccic emboli finally reach the kidney destination

Within recent years a publication from the Hamburg Pathologic Institute, read before the local society but as yet unconfirmed as far as I know, claims that, in all these cases of transitory or protracted sepsis with bacteremia, almost regularly a thrombophlebitis was demonstrable in the pulmonary circuit and that from these secondary foci tertiary foci develop in other parts. If this conception is verified, patients with cortical kidney abscesses that are adequately drained and still maintain a bacteremia may in turn, as the pulmonary thrombophlebitis takes care of itself, lead to further or quaternary metastases due to a thrombophlebitis in one of the cortical veins or to a thrombophlebitis in the main renal vein. It would seem, therefore, that the routes of the infecting agent may be rather difficult and involved. If the embolus lodges in the glomerular vessels or in one of the terminal branches of the arteries under the capsule, one or more localized abscesses are liable to develop. Apparently this process may be peracute or subacute, depending on the virulence of the organism and the patient's ability to combat the invader. In other cases, if the embolus lodges in a vessel well below the cortex at a bifurcation, a definite infarction develops, involving a typical conical area of cortex, which is liable to break down if the suppuration is not controlled and lead to innumerable small abscesses in the infarcted area, thus producing the picture of

7 In the first series thirty four out of sixty-one cases in the second series thirty two out of forty three cases according to the patients' histories

carbuncle of the kidney. There can be no doubt from innumerable observations that many of the former group of cases may resolve even without perforation into the caliceal system as one frequently sees evidence at operation of such a process particularly in the consolidated perinephritic fat. On the other hand, it is

Fig 1—Cortical abscess of anterior surface, curvature of the spine. Excretory urogram shows separation between second and third calices, irregular contour of kidney cortex, obliteration of the psoas. W. M. aged 13 years. Two weeks right lower quadrant pain. No pus in urine preoperatively. Operation revealed cortical abscess of anterior surface, subcapsular abscess. *Staphylococcus aureus* on culture. Negative blood culture and urine culture.

much less common and probably rarely seen in the carbuncular involvement of the kidney.

In my experience the great majority of both these types of kidney infection has been progressive and has finally led to involvement of the perinephric fat. If such cortical foci remain under the fibrous capsule of the kidney, as has been repeatedly seen in my cases, the perinephric fat is liable to be edematous at times adherent to the fibrous capsule over the abscess, and may even go on to frank suppuration, infected through the lymphatics or blood vessels which, though few in number, seem to connect the kidney cortex and capsule with the perinephric fat. If, on the other hand, such a cortical abscess is seen in the latter stage, it may have perforated the capsule of the kidney, as it usually does, and present a frank, massive contamination with suppuration in the perinephrium. A great deal of confusion has been caused in the interpretation of this pathologic process and in the origin of perinephric abscess by virtue of the fact that at operation in advanced cases of perinephric suppuration one may not recognize any evidence of kidney involvement. The cortical abscess, having ruptured and drained into the perinephric space rapidly heals so that what was a cavity in the cortex fills in with granulation tissue and on palpation the original crater or abscess cavity is flush

with the adjacent kidney cortex and not recognizable to the palpating finger.

I have been able to see, in the many operations for this condition, every stage of the pathologic process, e. g., cases in which the perinephric tissue was edematous only because of an underlying cortical abscess or abscesses, in which these cortical abscesses were uncovered only by decapsulating the kidney in situ; other cases in which a large perinephric abscess had developed and communicated with a definite crater or abscess in the kidney cortex, and others again in which there was no visible or palpable evidence of cortical abscess underlying the perinephric abscess. This last group of cases usually are of long standing and were more common when surgical therapy was delayed. Since earlier recognition of these cases, the last group has been rarely seen. In fact, in my last twenty cases decapsulation demonstrated the cortical kidney abscess in seventeen cases. In other cases the typical crater of the cortical abscess, which had perforated the capsule, was readily palpated. In other cases a superficial area of granulating tissue flush with the surface of the convexity of the kidney was all that was left to indicate the origin of the perinephric abscess. Untreated these perinephric abscesses, as is well known, may rupture into the paranephric space and thus drain down along the lumbar gutter toward the pelvis, appearing at the various rings in the inguinal region. They may perforate upward into the subdiaphragmatic space and thus into the pleura, or anteriorly into the bowel or perito-

Fig 2—Anterior cortical abscess. Pyelogram showing pushing apart of upper and second calices. S. F. aged 32. Four months furunculosis of lumbosacral region. One month chills and fever. No blood culture or urine culture. Physical examination showed tenderness over McBurney's point. At operation slightest edema lower pole. After decapsulation anterior surface abscess found, rest of kidney normal. Cultures of pus showed *Staphylococcus aureus*.

neum or posteriorly through the musculature under the skin in the lumbar region. Fortunately these extensive abscesses in the perinephric fat are rarely seen nowadays, though they were common thirty years ago. It must be admitted that involvement of the perinephric

fat may also arise from intrinsic disease of the kidney and pelvis, as seen in pyonephrosis, stones in the kidney, tuberculosis and the like but in these conditions the underlying disease usually dominates the picture and this type of complication is relatively rare.

Perforations of the bowel and appendix, as well as suppuration in the female pelvis and vertebral suppuration, may lead to such abscesses in the paranephric fat and perhaps also in the perinephric fat. This surely is a comparatively rare occurrence and it is difficult to understand the statement by Ombredanne⁸ that perinephric abscess in children is usually the result of appendicitis. Gerota's fascia is probably rarely penetrated by these abscesses, which lie behind this fascial plane in more or less direct communication with the retroperitoneal space.

The perinephric fat is undoubtedly in intimate lymphatic and vascular contact with the kidney and it is claimed that there is a separate arterial supply derived from the renal artery which goes to the perinephrium ("twigs," Quain). In view of this anatomic relation, a number of recent writers (Vermooten,⁹ Bugbee¹⁰) have reemphasized the possibility and probable frequency of perinephric suppuration produced by embolic infection of the perinephric fat. It is well known that the perinephric fat is remarkably avascular, despite this possible blood supply, and operating room observations have shown that this method of infection of the perinephric fat leading to suppuration must be a great rarity, as emphasized in years past by such experienced surgeons as Israel¹¹ and Jordan¹² and by many others, as well as by my own extensive experience.¹ While it cannot be denied, in view of the anatomic studies, that there is a possibility of such an infection of the perinephrium, the evidence of this method of infection is to date no more than flimsy.

In view of the pathologic condition as just described and the frequent suppuration in the perinephric fat associated with cortical kidney abscess in previously healthy kidneys, the bacteriology of the pus in both the cortical abscess and the perinephric tissue almost regularly shows the same organism, namely, *Staphylococcus aureus*. Occasionally, in a few of the cases the streptococcus has been isolated, and in a few rare cases *Staphylococcus albus*. In one case in which the latter organism was isolated, it was isolated also in the blood stream and caused the patient's death. In cortical abscess and perinephric abscess in previously diseased kidneys, on the other hand, *Staphylococcus aureus* has been an unusual finding, whereas colon bacilli, proteus, pyocyanus, the Friedlander bacillus and lactis-aerogenes have been identified. Usually the same organism has been identified in the voided urine, and at times, when cystoscopy and ureteral catheterization have been carried out, these bacilli have been found only on the side of definite disease. The culture from the urine in typical coccic cortical infections in previously healthy kidneys may fail to demonstrate *Staphylococcus aureus*. In twenty-eight cases so studied in my second series, eleven gave positive results. In some of these cases, colon bacilli seem to overgrow the cocci. There has been no systematic attempt made to examine the smears

of the centrifugated urine from the diseased kidney reliance having been placed mainly on cultural examinations. In a considerable number of these cases, blood cultures have been made and *Staphylococcus aureus* or *Streptococcus anhaemolyticus* and haemolyticus have been grown. In the bacillary cases there have also been repeatedly positive blood cultures. In both groups of blood cultures invasion of the blood stream is usually temporary, and despite positive blood cultures, if proper treatment is carried out the sepsis disappears and the blood stream becomes sterile.

REVIEW OF SIXTY-ONE CASES

The following observations are based on a review of sixty-one cases treated prior to 1926 and reported by Dr. Paul Aschner,¹⁴ and forty-three more recent cases in which operation was performed.¹⁵ In this last group, some new points of view have been developed, while in general most of the fundamental observations in our

Fig 3—Anterior cortical kidney abscess. Excretory urogram, middle calices not filled. S. C. aged 48. Nine days symptoms left upper quadrant left loin pain. Etiologic factor hemorrhoidectomy two months previously required catheterization after operation resulted in nocturia, frequency, no pus in urine. Two positive blood cultures *Staphylococcus aureus*, *Staphylococcus albus*, *Streptococcus haemolyticus*. Operation showed cortical abscesses anterior surface perinephritis edematous fat. Uneventful recovery.

service, as published by Aschner, have been confirmed. Males, as is to be expected, are more frequently involved (thirty-one to twelve), and the majority of cases fall between the ages of 20 and 50. In forty-three cases, thirty-eight showed *Staphylococcus aureus* in cultures of pus, three showing a mixed infection. In thirty-two cases there were perinephritis and perinephric abscess, as well as cortical abscesses. In nine cases the kidney was not exposed or visualized according to the records. In thirteen cases the cortical abscess was antero-lateral. If this location of the abscess, almost 30 per cent of the last forty-three carefully observed patients holds for other series, one can well understand

¹⁵ In addition there were five patients who presented rather typical symptoms and got well without surgery as well as two patients who died too toxic for surgery.

the failure to appreciate the intimate relationship between the cortical kidney suppuration and perinephric abscess. Without decapsulation, these abscesses would have been regularly missed. Incision and drainage alone of the perinephric abscess possibly would have sacrificed the involved kidney, surely protracted the convalescence and perhaps even have lost the patient. In a study of the blood cultures, there were seven staphylococcemias out of a total of twenty-six studied in this manner. Only a fraction of the cases were studied from this standpoint and usually only the very sick or persistent and puzzling cases.

The clinical picture of metastatic, cortical, coccic infection has become much clearer since physicians and surgeons have been on the lookout for these cases. As Linder¹⁶ has recently written, the general surgeon sees more of these cases than the urologist, as they are referred to the general surgeon by the medical men

Fig. 4—Excretory urogram showing good function of both kidneys. Diffuse shadow in left lumbar region obliterating margin of psoas muscle and curvature of spine toward the opposite side where psoas margin is clearly seen. S. M. aged 16 years. Antecedent skin infection, cortical abscess of left kidney, edema of perinephric fat.

under the impression that they are acute abdominal conditions. In fact, it has been my experience as a general surgeon that the urologist often fails to recognize this condition, probably owing to lack of extensive experience. During recent years particularly, the clinical picture of these cases, coming as they do to the surgeon earlier, is totally different from what it was some thirty years ago, when these patients presented themselves with bulging tender, lumbar abscesses, often associated with psoas contractions, simulating either Pott's disease of the spine or hip disease. At the beginning of the century the orthopedic surgeon frequently described the end result of these cases, as they were referred to him for the foregoing symptoms, before the correct diagnosis was made. Some few cases still

present a picture that is quite baffling, and only a tentative diagnosis, followed by an exploratory operation, helps to clarify the underlying pathologic condition.¹

As the clinical picture may vary from a very acute, fulminating process with chill or chills, high temperature and pain in the back to that of a subacute or chronic septic condition, it is fair to say that the clinical picture presented by this type of infection may be protean in character. Fortunately in the great majority of cases the picture is rather typical and therefore easily recognized. In the minority of cases the obscure picture and the bizarre behavior of the patient had led to many late diagnoses, in some cases a year or more following the beginning of the infection. It can readily be understood why the picture varies. In all probability this depends not only on the degree of virulence of *Staphylococcus aureus* and the resistance of the patient but also on the local pathologic condition and the progress of the disease. While the pus focus is under the kidney fibrous capsule and therefore under considerable tension, the symptoms may be marked and striking, and as the cortical abscess ruptures into the perinephrium and in turn localizes in this fatty tissue, symptoms may subside temporarily, only to become more definite as tension develops in the perinephric space. Again when the perinephric abscess breaks through the fascia of Gerota tension disappears and many of the symptoms temporarily abate. Then again as pus ruptures downward and descends between the two leaves of Gerota's fascia toward the pelvis, the symptoms may subside until the tissue reaction reencloses the purulent accumulation. Some few cases may rupture into the caliceal system or the pelvis and drain off satisfactorily, with disappearance of symptoms.

In view of these peculiar developments, one often gets the impression that the patient is definitely getting well spontaneously, which may take place, but innumerable cases of this sort have been seen by other observers as well as by myself, in which finally, despite apparent repeated periods of convalescence and improvement operation became necessary and disclosed in addition to the perinephric abscess further change, either a cortical abscess or carbuncle of the corresponding kidney.

The characteristic symptoms of this disease are a rise in temperature with or without chill, with pain in one or both lumbar regions. On physical examination the kidney usually cannot be felt, and if palpable strange to say, it may be movable. There is regularly a definite jar or "punch" tenderness over the involved kidney. If the elevation of temperature continues, there is a progressive, often impressive, loss of weight and a progressive anemia. The patient becomes pasty looking and suggests sepsis. Leukocytosis is almost always present while the patient has fever. The examination of the urine at this stage may show little or nothing. There may be some red blood cells²⁰ in the voided urine, some leukocytes or a trace of albumin as a result of the febrile reaction, possibly from the affected kidney, possibly from the second kidney. In view of the fact that the cortex is involved in these cases it is not surprising that the urine is clear and practically negative macroscopically and microscopically. Moreover, the functional tests of the kidney and the blood

17. Though the clinical picture may seem clear and typical exploration may expose a paraneuritic abscess due to vertebral osteomyelitis, metastatic psoas abscess, pericholecystic abscess, pericolic suppurative due to carcinoma and the like very rarely a subcapsular hemorrhage caused by periarthritis nodosa (Dantes¹⁸, Wever¹⁹) and occasionally no pathologic condition at all.

20. Gross hematuria is unusual.

examination for retention products are liable to be negative. Cystoscopy in these cases should be carried out only after a preliminary roentgen examination. The chief value of cystoscopy is to demonstrate that both ureters are patent and that the patient is not suffering from a completely blocked kidney. In practically all these cases at their inception it is essential to rule out an acute, infected, completely obstructed hydronephrosis.

The roentgen examination, as pointed out by a number of writers (B. Alexander,²¹ B. Revecz,²¹ H. Laurell,²¹ J. R. Carty,²¹ L. Friedman,²¹ P. Lipsett²¹), in the flat plate may frequently help clarify the diagnosis by demonstrating a curvature of the spine away from the area of pain and tenderness and a partial or complete obliteration of the sharp edge of the corresponding psoas muscle. In eighteen cases out of twenty-nine these corroborative signs were noted.

In 1928 I²² called attention to the fact that obliteration of the psoas margin and curvature of the spine away from the painful or tender kidney in the absence of an obstruction of the ureter leading to hydronephrosis and in the presence of macroscopically clear urine was a corroborative sign of perinephric suppuration. Since then I have noticed this sign repeatedly in cortical kidney abscess without frank perinephric suppuration, caused in part by edema in the perinephric fat. This analysis of the situation presented in the ordinary flat x-ray plate places the value of such an examination on a much firmer basis than do the observations of other writers.

It is amusing to see cases reported with flat roentgenograms in which the legend reads "There is no curvature of the spine away from the involved kidney," when even in the reproduction it takes no particular keenness to recognize such a curvature. As similar pictures may be induced by an obstructed, infected hydronephrosis, a cystoscopy is essential to exclude this condition. In some obscure cases the flat roentgenograms of the kidney area may show a gradual enlargement of the kidney shadow, which in the absence of an obstruction in the ureter can only mean that while under observation the kidney has been gradually more and more involved, producing an increased shadow. Occasionally in the roentgenogram one may see an irregularity or hump corresponding to a suppurative process either under the capsule or in the perinephrium, which also may help in the more chronic cases in elucidating the clinical picture. Actual displacements of the kidney have been described, but they must be very rare. Some authors believe that they can diagnose cortical abscesses by variations in the density of the kidney shadow, which is more than I have been able to do.

Excretory urography and retrograde pyelograms have repeatedly helped out in the diagnosis of some of the subacute and chronic cases by demonstrating either a pushing apart of the calices above and below the abscess or by demonstrating, particularly in the carbuncular cases, compression phenomena involving the pelvis and two or more calices simulating neoplasm of the kidney (ten cases out of sixteen). These changes in the roentgenograms are seen not infrequently in cortical abscess, even before frank pus develops in the perinephric space. Another x-ray observation, especially in upper pole involvement, is a gradual pushing up of the diaphragm or fixation of the diaphragm due to local edema or exudate. All in all, the value of the roentgen examination in these cases has been very much underestimated,

as evidence of trouble is demonstrable in this way in more than half the cases.

In a moderate number of cases there may be radiating pain along the genitocrural nerve and some mild urinary frequency. Rarely there are colicky pains. Many cases at the inception present no symptoms or definite signs referable to renal disorders and resemble general infections, such as influenza, typhoid or even sepsis, some suggest pneumonia, and others in which there is pain on respiration are mistaken for pleurisy. If the cortical abscess is in the upper pole, the latter clinical pictures are readily simulated.

In some of the subacute or chronic cases in which the temperature has gradually dropped, and in which local pain and tenderness have disappeared, I observed some years ago that it might be possible to activate the quiescent abscess with the use of ordinary Staphylococcus aureus vaccine. This procedure was based on clinical observation of cases of bilateral cortical abscess in which the patient at the time of the first operation had symptoms localized to one side and shortly thereafter developed symptoms referable to the second kidney. At the exposure of the second kidney, the same pathologic condition that had been disclosed at the first operation was found. Apparently the condition had existed the same length of time, and the absorption following the first operation had activated the foci in the second kidney. A number of cases in which vaccination with stock vaccine of Staphylococcus aureus has been carried out seemed to respond with fever, pain and development of local tenderness. In view of the fact that this did not happen regularly, it is only fair to say that the apparent activation may have been accidental, though it seemed to be a direct result of the injection. I believe that in obscure cases this should be attempted. Intercurrent infections of the upper respiratory tract, as well as skin infections, may also reactivate quiescent coccic foci in the kidney, which supports the foregoing observations.

The clinical pictures of the typical, acute cases, whether associated with bacteremia or not, should be recognized and should be treated surgically by incision, drainage and decapsulation²³ *in situ*. If this is carried out, the wound should not be sewed tightly, as it is always liable to be infected from the staphylococcus pus. Adequate rubber dam in front and behind the decapsulated kidney should be left in place for drainage and usually, if the abscesses are thoroughly drained and do not involve the whole kidney, decapsulation is curative. Only two cases eventually required nephrectomy. Whereas with a clear cut clinical picture—persisting fever, jar tenderness—operation is indicated, should the symptoms abate and suggest spontaneous resolution, a watchful waiting policy is indicated.

Variations in the clinical picture from the simple, more or less regular course, deserve special mention, and I shall take the liberty of describing a number of obscure cases rather fully to illustrate the perplexity that can be produced by this type of metastatic, cortical, coccic kidney abscess. Before describing these unusual cases, it must be emphasized that there is a considerable group of cortical abscesses which involve the anterior surface of the kidney (thirteen cases out of forty-three), which may eventually rupture into the anterior perinephric space and thence rarely into the peritoneal cavity, and which appear as acute abdominal disease, often suggesting either a gallbladder infection, appendi-

²³ In very long standing neglected cases of perinephric abscess in which the kidney is thoroughly bound down and encased decapsulation *in situ* may be unwise unnecessary or even impossible.

²¹ Cited by Beer and Hyman²² pp. 63-84.

citis, acute pancreatitis, occasionally liver abscesses or even a visceral perforation. Sometimes lower pole cortical abscesses will produce the same type of irritation of the peritoneum, and, if on the patient's right side, the aforementioned clinical pictures may be simulated. On the left side, fortunately, this confusion is rare, though at times antereal suppuration has led to the mistaken diagnosis of a colonic tumor, which may have to be excluded by a barium sulfate enema. These cases of antereal suppuration, of which numerous examples have been described by me and members of my staff in years past, naturally are referred to the general surgeon rather than to the urologist. Both groups if not aware of the clinical entity, are liable to be confused and approach the disease transperitoneally. Such cases are presented with unusual frequency at medical societies, and a recent case presented by Cutler²⁴ shows very clearly how serious a condition can develop from a misinterpretation of the clinical picture. Such abscesses on the anterior surface of the kidney drained transperitoneally, invite all sorts of trouble in addition to peritonitis and may require reoperation through the lumbar route for adequate drainage of the cortical and perinephric focus. On the other hand if the condition is recognized, as it should be, a typical lumbar incision with decapsulation and drainage of the cortical abscess rapidly leads to cure.

The importance of leaving these wounds fairly wide open is to be emphasized, as every once in a while one must digitally explore the wound and sweep one's finger around the involved kidney to control any possible retention or to break into any new subcortical abscesses that may have come to the surface. Although usually after the primary decapsulation and incision of these abscesses the postoperative course is uneventful, at times retention with elevation of temperature takes place and the procedure can be readily carried out in bed with complete evacuation of the abscess and rapid improvement in the patient's general condition. In some of these cases, when a large vessel has been obstructed and an infarction has developed producing a carbuncle, it frequently is possible somewhere around the third week of the disease to enucleate the infected wedge with a blunt instrument or even with the gloved finger. About this time separation from the normal kidney parenchyma seems to take place. The enucleation of the infarcted area the first time it is seen or carried out is a surprise, as well as a satisfaction to the surgeon. Usually very little bleeding takes place and a small iodoform packing for the purpose of drainage is introduced into the cavity thus produced.

In treating all these cases, the surgeon has to use his judgment as to whether decapsulation will suffice to cure the patient. In my experience decapsulation²⁵ almost invariably has led to a complete cure except when extensive, multiple carbuncles or innumerable abscesses were present, and even here if the patient's condition will permit, a decapsulation with incision of the abscesses or with enucleation should be done as the first step. If the kidney is riddled with abscesses decapsulation may be ineffectual but a secondary nephrectomy, if it should be necessary, can readily be done, as the kidney lies free in the bottom of the wound and can easily be delivered and its pedicle tied off. (Two cases out of forty-three required nephrectomy.)

In closing this paper I will describe a few of the unusual cases referred to so as to call attention to some

of the very difficult clinical pictures presented by these metastatic, cortical, kidney abscesses, due to cocci

REPORT OF FOUR CASES

CASE 1—*Right kidney carbuncle, anterior surface, perinephric abscess, left kidney perinephritis following slim infection. Incision and decapsulation of right kidney with enucleation of carbuncle. Eighteen months later, exploratory operation of left kidney, and separation of perinephric adhesions.*

S. K., a woman, aged 25, admitted to the hospital Nov. 2, 1925, had been perfectly well up to six months before when she began to suffer from nausea and vomiting with cramplike pains across the epigastrium. These pains recurred every two weeks. Two weeks before admission she had suffered pain in the right hypochondrium radiating to the right shoulder, associated with nausea and vomiting. The pain was dull and persistent. The night before admission, the patient had chills, the temperature rose to 103 F. She thought she had had elevated temperature since the preceding July. For the past two weeks there had been frequent diarrheal stools without blood, there were no urinary symptoms. Two months before admission the patient had a carbuncle of the neck. On physical examination there was a round, palpable mass in the right upper quadrant, which suggested the diagnosis of subacute gallbladder inflammation. There was also some right costovertebral tenderness as well as percussion tenderness over the liver. Roentgenograms of the chest were negative. Examination of the stools for tuberculosis and amebas was negative. Solitary liver abscess was considered as a possibility and emetine was employed with the hope of controlling or ruling out this condition. Cystoscopy was completely negative, but the pyelogram of the right side showed the pelvis slightly enlarged, the upper calices drawn out and incompletely filled. The lower calices were only partially visualized. The whole picture suggested the possibility of pressure against the caliceal system. The patient's fever continued and, as no focus of infection was revealed by study of the gallbladder, intestinal tract and urinary tract, the persistent fever and moderate local tenderness posteriorly over the kidney and in front of the right kidney, with the history of carbuncle or furuncle of the neck, led to the tentative diagnosis of cortical abscess or carbuncle of the right kidney with perinephric abscess, despite the fact that the ureteral specimens were negative in both smear and culture.

December 4 the right kidney region was explored and on the anterior surface of the middle third a perinephric abscess containing *Staphylococcus aureus* was encountered, and under the capsule of the kidney a large, necrotic carbuncle was discovered. The carbuncle was about the size of a silver dollar (38 mm.). It was shelled out of the kidney with the finger, and the cavity was packed lightly with iodoform gauze. Following this the patient improved for a while and then began to have some elevation of temperature with pain and tenderness over the left kidney. The kidney was not enlarged, the temperature was low, and it was suspected that the patient had a cortical abscess in the second kidney. Repeated doses of *staphylococcus vaccine* were employed without any increase in tenderness or rise in temperature. The right wound gradually closed and as the temperature became normal the patient was discharged.

Four months later she was readmitted to the hospital for a small persistent sinus of the right lumbar region which was cured. Granulation tissue was nonspecific and the wound closed rapidly. Cystoscopy and urine cultures from both kidneys at this time were negative and as the temperature subsided and pain disappeared the patient was again discharged.

She was readmitted for the third time in May 1927, complaining again of continuous dull pain in the left upper quadrant radiating to the left lumbar region. She was about 35 pounds (16 kg.) below her normal weight and had a persistent temperature up to 101. There were frequent episodes of diarrhea with passage of large amounts of fresh blood. The lower pole of the left kidney seemed irregular and slightly tender. Between the two admissions the patient had an attack of measles and arthritic pains in the spine, arm and shoulder. Cystoscopy at this time was completely negative, a pyelogram of the left kidney showed no abnormality. In view of the conditions found it was suspected that the patient might have a chronic cortical abscess or carbuncle of the left kidney, and

²⁴ Cutler C. W. Jr. Ann Surg. 102: 478 (Sept.) 1935.

²⁵ In cases of uncontrolled diabetes nephrectomy as the primary procedure may be necessary.

exploratory operation was done May 27, 1927, which revealed numerous firm, fibrous, perinephric adhesions. The kidney was normal in size, the pelvis of the kidney was empty, containing no stones. After separation of the kidney from these adhesions, a small, yellowish area was found near the hilus, which suggested a possible old cortical focus from which the infection of the perinephric space had developed. No frank pus was seen anywhere. The postoperative course was uneventful. The patient was discharged from the hospital June 16, 1927, having gained 20 pounds (9 Kg). The pains on the left side had completely disappeared, though she still had slight discomfort at the site of the wound. There were occasional rises in temperature. There was no more diarrhea with blood, the urine continued negative, and the patient resumed her normal activities. Cultures of the urine and guinea-pig inoculations were negative on the last admission, as was the cystogram. There was no reflux up either ureter. During the last six years the patient has been perfectly well except for an attack of undulant fever and a few accidental fractures, and she reported in 1935 that she was in perfect health.

CASE 2—Multiple antercortical abscesses simulating gallbladder disease. Staphylococcus aureus. Patient under observation and having a febrile course for eighty-two days prior to operative therapy. Decapsulation of the right kidney with incision and drainage of multiple cortical abscesses due to Staphylococcus aureus. Rapid convalescence, with a gain of 70 pounds (32 Kg.)

C. R., a woman, aged 38, for the five months prior to admission had complained of malaise and pain in the back. A few weeks before admission there was a sharp pain over the whole back, which lasted for a week. There had been pain in the right hypochondrium and right loin for the past two weeks associated with nocturia and a temperature up to 102. The bowels were constipated. On physical examination there was some right costovertebral tenderness as well as some tenderness anteriorly over the gallbladder, in fact, the tenderness over the gallbladder suggested the possibility of gallbladder disease, though the tenderness was not very severe. The patient's urine showed a few red blood cells, and culture showed *Streptococcus viridans*. There was moderate leukocytosis, 12,500, with polymorphonuclear cells 80 per cent. Cystoscopy was negative. On the sixth day after admission the temperature rose to 103, there was definite right upper quadrant tenderness. A gallbladder series showed no pathologic condition in the gallbladder. On the seventeenth day after admission, urine culture showed atypical colon bacilli. The next day the patient developed pain and stiffness in the right upper extremity. A control roentgenogram of the genito-urinary tract was again negative. The patient continued to have a high temperature and developed pain in the right shoulder and arm. On the twenty-first day the patient had a chill, the temperature rose to 103 and the first positive blood culture showed *Staphylococcus aureus*. On the twenty-eighth day she developed again slight tenderness of the right loin, and urine culture at this time showed *Staphylococcus aureus*. Two days previous to this there was a second positive *Staphylococcus aureus* blood culture. A roentgenogram of the abdomen showed obliteration of the right psoas margin. To date the only diagnosis that seemed feasible was mild sepsis due to *Staphylococcus aureus* with the possibility of a right renal cortical abscess. To emphasize the local renal symptoms the patient was given *Staphylococcus aureus* vaccine, at first 150 and then 250 million. The only result of this activating experiment was generalized drawing pains. As the tenderness in the right kidney region was not accentuated and as the symptoms were not clear cut enough to justify exposure of the right kidney, the patient was retransferred to the medical service on the thirty-fourth day with a diagnosis of consolidation of the lung, perhaps pulmonary furunculosis. Shortly after this the blood culture became negative, the elevation of temperature continued. On the twenty-ninth day the right side of the chest was aspirated, nothing was obtained. By the forty-seventh day the temperature was still high, 104, and there was slight clubbing of the fingers. There was no definite costovertebral tenderness. On the fifty-first day the record shows that there was no adequate evidence for surgical intervention. The patient's chest was again aspirated with negative results. On the fifty-second day cystoscopy was again carried out and was negative. The right and left kidney appeared

normal. On the fifty-fifth day hemoglobin was 52 per cent, and the patient was given a transfusion. On the sixty-second day there was a swelling near the anus, subcutaneous inflammation. On the seventy-first day the patient was afebrile. On the seventy-fifth day there was a recurrence of mild, right costovertebral tenderness. On the seventy-ninth day the temperature rose again, the patient had general pains and a slight pain in the right flank, without any urinary symptoms. On the eightieth day definite resistance to the right of the umbilicus under the right upper rectus and irregular nontender mass was recognizable. On this day another blood culture was made and proved positive for *Staphylococcus aureus*. Tenderness in the right costovertebral angle was increasing by the eighty-second day and it seemed fairly definite that the patient had an antercortical cortical abscess, which had originally simulated gallbladder disease and subsequently had become quiescent. Indications for operation were based on the original right lumbar pain, recurrent right lumbar tenderness, normal urine, positive *Staphylococcus aureus* blood culture and fever. On the eighty-second day, therefore, an incision and drainage with decapsulation of the right kidney was carried out and at the same time multiple cortical abscesses on the anterior surface of the upper half of the kidney were incised and in part excised. The pathologic report of the tissue removed showed chronic and acute purulent inflammation of the kidney capsule and kidney tissue. Culture of the pus showed *Staphylococcus aureus*. Following the operation there was some pyuria due to breaking into the caliceal system at the operation, but the patient made a rapid convalescence and gained 70 pounds (32 Kg.) in a short time.

CASE 3—Bilateral, multiple cortical kidney abscesses following skin infection. Left kidney decapsulated, multiple cortical abscesses exposed as well as a perinephric abscess. Pus showed Staphylococcus aureus. Apparent uneventful recovery, rise in temperature. Thirteen days following first operation, right kidney exposed and decapsulated for multiple abscesses. Both wounds closed five weeks after first operation. Patient discharged well.

J. L., a man aged 22, admitted to the hospital May 16, 1922, and discharged June 23, 1922, was well until ten weeks before admission when he had a mild infection of the toe. Two weeks later he developed an infection of the right index finger and two weeks later suffered with a cold in the head and while in bed had an abscess of the scalp. At this time there was some fever for two or three days. Seventeen days prior to admission he developed some pain in the left lumbar region, with fever of irregular character and was confined to bed. Since then he had pain in the left lumbar region and tenderness, irregular temperature, no chills, and no urinary symptoms.

He was a very pale, septic looking patient. His general physical examination was negative, but in the left lumbar region there was marked tenderness, though no mass could be felt. The blood count showed 29,600 white cells with 86 per cent polymorphonuclears. Urinalysis showed a trace of albumin, some casts and a few white blood cells. Preoperative roentgen examination of the genito-urinary tract was not satisfactory, but showed no stone. The preoperative diagnosis was cortical abscess of the left kidney with possibly perinephric abscess.

May 16 under gas a left lumbar kidney incision was made and a perinephric abscess encountered. The thickened capsule of the kidney was turned back and multiple cortical abscesses were incised without delivering the kidney. The capsule was much thickened and edematous. In one place the cortical abscesses were so grouped as to suggest a suppurating infarct or carbuncle. Rubber dam was placed in front and behind the kidney and a tube between the two sheets of rubber. The wound was left wide open. The culture of the abscesses showed *Staphylococcus aureus*. From May 17 to May 23 the wound was irrigated daily and the kidney regularly palpated in the wound and several soft suppurating areas in the cortex were broken up with the finger. During this period the temperature gradually diminished and the patient seemed to be convalescing when suddenly on the 23d his temperature rose to 105. The wound was then explored with the finger and considerable pus was evacuated, the kidney being easily palpated in the bottom of the wound. There was some urinary leakage from the

kidney into the dressing May 24, the next day, the temperature dropped to normal, and it seemed as if the previous day's digital exploration had controlled the situation. Throughout this period the urine was clear showing a trace of albumin, a few casts and occasionally a few pus cells.

May 25 to 26 the temperature again rose. Blood culture was negative and tenderness was recognized in the right lumbar region. May 27 the temperature rose to 103.8 and in the right lumbar region, on deep pressure, tenderness was somewhat more marked. Exploration with the finger of the left lumbar wound gave no explanation for the rise in temperature, and on May 29 it was decided that the right kidney area, which was tender, was probably the seat of cortical abscesses with some perinephritis. On that day a right lumbar incision was made and the lower pole of the right kidney was found necrotic and surrounded with thick green pus, the perinephric tissues were thickened and edematous. The right kidney was decapsulated in situ just as the left had been, and multiple abscesses, some as large as cherries were opened bluntly. Drainage was carried out with two sheets of rubber dam on each side of the kidney and tube between and the wound was left open without any sutures. After this operation, the wounds on both sides being dressed and irrigated daily and the rubber dam with drawn gradually the patient's temperature became normal within two weeks. During this period several small areas in the right kidney were bluntly opened at dressings with the palpating finger. From the right wound there was also moderate urinary leakage. Beginning with the third week the patient had sufficiently recovered strength to be out of bed, and on June 23, about five weeks after his first kidney operation he was discharged from the hospital. Since the operation the patient has gained about 40 pounds (18 Kg).

CASE 4—Subacute carbuncle of the upper pole of the left kidney. Patient sick five months before first admission having lost 30 pounds (13.6 Kg). Complete workup led to no diagnosis. Four months following first discharge patient apparently well then severe pain in the left kidney region with elevation of temperature. Exploratory operation disclosed a thick perinephric capsule, perinephric abscess under the diaphragm and carbuncle involving the upper third of the kidney which demanded nephrectomy. Pus showed Staphylococcus aureus.

E. G.²⁰ a man, aged 24, seen Oct 25 1915 had been sick five months. His trouble began with pain in the left side of the abdomen radiating to the back. It came on suddenly and recurred. He had chills, fever and sweats prior to admission and had lost 30 pounds (13.6 Kg). On admission the examination was negative except for slight tenderness in the left lumbar region. The urine was clear but contained a faint trace of albumin, a moderate number of red cells and a few pus cells. Cystoscopy was negative. There was good indigo carmine excretion on both sides. The urea concentration in what proved to be the pathologic side was higher than on the normal side (12 per cent vs 0.8 per cent). The urine of both sides showed an occasional cast but no pus cells or tubercle bacilli and was culturally sterile. The ureteral washings revealed no scratch mark. The roentgenogram of the genito-urinary tract showed normal kidney outlines. The blood count was normal. There was no pain and no elevation of temperature while the patient was at the hospital. October 30 as he felt perfectly well, he was discharged with the diagnosis in doubt (nephroptosis?). The following four months the patient felt absolutely well, and then he had a severe attack of pain in the left hypochondriac and left lumbar regions. He was sent to Bellevue Hospital. He had a temperature of 101. In the left lumbar region the lower pole of the kidney was palpable and felt moderately enlarged and it was slightly tender. Cystoscopy again was negative and there was no hydro-nephrosis in the left kidney. The roentgen examination was again negative. In view of the repeated attacks of pain during the last nine months the recent temperature elevation and the palpable enlarged lower pole of the left kidney it was deemed advisable to explore. No definite diagnosis had been made though it was thought that we were dealing with a kidney tumor or a painful perinephric inflammation. April 13, 1916 an exploratory operation was carried out and much to my surprise the kidney had to be removed for chronic carbuncle with massive perinephritis and perinephric abscess under the diaphragm. The conditions found at operation were most

interesting. The left kidney was firmly fixed above the lowest rib, within a thick shell of exudate which was almost an inch thick at the level of the twelfth rib and surrounded it in such a manner as to suggest a sarcoma of the rib. This had undoubtedly impressed me as the lower pole of the kidney. The twelfth rib was resected, and by cutting through the infiltrated tissues of the perinephric region, near the upper pole of the kidney, I opened a fair sized abscess. By the coarsest dissection the thickened perinephric exudate and kidney were partially freed so that I could orient myself. It was then apparent that the perinephric tissues had been consolidated by an inflammatory process into a thick shell of scar tissue and that within this rind lay the diseased kidney. In places this capsule was almost an inch thick. After excising most of the enveloping capsule that appeared in the wound, I removed the kidney. Pus was seen to exude from the cortical kidney abscesses into the perinephric tissues and probably communicated with the large abscess over the upper pole. The pus showed the presence of *Staphylococcus aureus*. The kidney contained a large purulent infarct with thousands of small abscesses—a typical carbuncle. The convalescence was uneventful except for a wound infection and the patient has remained well.

45 East Eighty-Fifth Street

OBSERVATIONS OF THE GALLBLADDER AND BILE DURING PREGNANCY AT TERM

MILTON G. POTTER, M.D.

BUFFALO

The frequency of abdominal distress in the upper right quadrant of the abdomen of women during antepartum and postpartum periods led me for the past five years into the routine practice of inspecting, palpating and aspirating the gallbladder in all my cesarean cases. The procedure was simple, because I use the high incision above the navel.

First of all, the uniformly distended bladder made me interested and inquiring and then the hope of gaining more information suggested the bacteriologic and later the chemical analysis of the aspirated bile. I found that the results were difficult to interpret in many cases, and at the same time the procedure was accompanied with no dangers or complications.

However, it is not within the scope of this paper to enter into the physiology of the liver, but some of the observations, readings and conclusions may be of interest and promote further investigation, because a search of the present-day literature discloses that the study of the bile of pregnant women at term has never before been attempted.

In a review of the literature by Ivy¹ on the subject of the evacuation of the gallbladder, he notes that it is an established fact that the sphincter of the choledoduodenal mechanism is essential for the filling of the gallbladder as well as the tone of the gallbladder musculature.

In attempting to evaluate the various factors concerned in emptying the gallbladder, he states that the contraction of the gallbladder musculature is excited by the hormone cholecystokinin and by the reflex nervous mechanisms that bring about an increased intravesical pressure, which with a relaxation of the sphincter of Oddi and the duodenal musculature permits the flow of bile. He also states that duodenal peristalsis is not essential but may assist evacuation.

¹ Ivy A. C. *Physiol. Rev.* 14:1 (Jan) 1934 cited by Ivy A. C. and Bergh G. S. *The Applied Physiology of the Extrahepatic Biliary Tract* J. A. M. A. 103:1500 (Nov. 17) 1934.

by possibly exerting a milking action on the intramural portion of the common duct and that intra-abdominal pressure per se plays no role in the gallbladder evacuation

Interesting studies on the reflex inhibition and excitation of the gallbladder from electrical stimulation of the gastro-intestinal tracts of cats at various levels were made by Birch and Boyden,² and they noted that no reflex contraction was ever initiated from any portion of the intestine but that stimulation of the pars pylorica showed a sudden contraction of the gallbladder. They also noted that relaxation occurred when various portions of the duodenum jejunum and cecum were stimulated, and that the cecum was most sensitive in not only bringing about inhibition of the gallbladder evacuation but also with regard to pain. Boyden³ also noted that stimulation of the plexus which accompanies the left gastric artery induced relaxation of the contracted gallbladder.

Ivy also states in his review that Mann and Higgins observed in pregnant dogs, guinea-pigs and gophers that the gallbladder either does not empty or empties only partially, but there seems to be an exception in that the gallbladders of some pregnant dogs do empty quite normally. Their contention is that this might be due to disturbed gastro-intestinal motility or peristalsis.⁴

Westphal⁵ observed that the tone of the sphincter of Oddi is increased in pregnancy.

Kalk and Schondube⁶ report that the gallbladder of pregnant women contracts earlier and more quickly than that of nonpregnant women after a subcutaneous injection of solution of posterior pituitary.

Failure to visualize the gallbladder in more than 50 per cent of the primiparas who had no history or clinical evidence of biliary tract disease was noted by Levyn, Beck and Aaron⁷ while Crossen and Moore⁸

failed to visualize the bladder in twenty-two of twenty-five pregnant women at the fortieth week. They believed that their results were due to technical roentgenologic difficulties.

In 390 cesarean sections in normal pregnant women at term, I found approximately 75 per cent with large atonic globular, distended gallbladders. Why?

Is it a functional motor disturbance with a spastic sphincter of Oddi, accompanied by a marked atonic distention of the gallbladder as Westphal indicates, or is it because these patients had not eaten before these specimens were taken? Ivy believes the explanation of "atonic distention" most reasonable but is at a loss to explain the cause. He⁹ offers the suggestion of reflexes from the colon with associated constipation.

Considering the work of Birch and Boyden, and realizing that the majority of pregnant women complain of constipation, Ivy's suggestion that constipation might be at least one exciting cause which promotes relaxation of the gallbladder with the resultant distention seems also to me to be a reasonable contributing factor. It would also aid in giving a partial explanation of the distress these women experience in the upper right quadrant.

My observations bear out the observations of Mann and Higgins,⁴ and I am in accord with their suggestion that one of the reasons gallbladders do not empty is disturbed gastro-intestinal motility.

In my series, 2 cc of solution of posterior pituitary was injected after the uterus had been closed and before the gallbladder was aspirated. No effect was ever noted on the contractility of the gallbladder. This distended organ remained distended, while the effect of the pituitary extract on the uterus was most marked. These observations are contrary to the work of Kalk and Schondube⁶ whose report I have previously mentioned.

I believe that there is marked stasis of bile in 75 per cent of the cases referred to, because of the appearance of the aspirated bile, which is thick tarry and viscous. This would explain the frequent failure of visualization of the gallbladder during pregnancy, as noted by Levyn, Beck, Aaron, and Crossen and Moore⁷

BACTERIOLOGIC OBSERVATIONS

Three hundred and ninety samples of bile were studied bacteriologically in two Buffalo Hospital laboratories. I am indebted to Dr Margaret Warwick of the Millard Fillmore Hospital and Dr W J Rose of the Buffalo General Hospital for the bacteriologic work. The bile was obtained by introducing, at an angle, a hypodermic needle (gauge 24) into the gallbladder, and this was easily done because of the greatly increased pressure within the gallbladder. Clinically it was found that postoperative nausea and vomiting were

was one culture of pneumococci (this gallbladder contained many stones). There was one culture of gram-positive diplococci. In one case gallstones were palpated but the culture was negative.

There were fifty-five evident contaminations. Staphylococcus aureus, twelve, Staphylococcus albus, seven, saprophytic cocci, two, saprophytic gram-positive spore bearing bacilli, twenty-four.

These observations are at variance with the work of Dr Scuti¹⁰ of Italy and Dr Lloyd Arnold of the University of Illinois. Dr Scuti concluded from his

markedly reduced by the release of this intra gallbladder pressure.

Approximately 30 cc of bile was removed in each case and placed in a sterile bottle. At the beginning of this investigation frequent contaminations were noted, but this error in technic was later corrected. The samples were immediately sent to the laboratory. They were cultured in plain broth, in dextrose broth and on agar slants. About one half were cultured anaerobically. Six specimens showed pathogenic growths. In other words, 2 per cent of the patients had pathogenic organisms in the bile. One culture showed a mixed growth of streptococci and staphylococci. There were three pure cultures of Bacillus coli. There

experiments that, in the majority of animals at least, a condition of latent microbism is present in the bile content of normal gallbladders, while Dr Lloyd Arnold, who worked on dogs several years ago, found bacteria in about 50 per cent of the cases and in all the strain of bacteria was not pathogenic. He also tried to raise the pathogenicity by passage through dogs without success.

The data in table 1 of the blood cholesterol of forty-one patients at term, as determined by the Bloor method, bear out the known fact that there is a general increase of cholesterol in the blood during pregnancy.

10 Scuti cited in Rome letter J A M A 103 2043 (Dec 29) 1934

Forty-six per cent of the patients had blood cholesterol between 1 and 200 mg per hundred cubic centimeters, forty-eight per cent of the patients between 200 and 300 mg, and 6 per cent between 300 and 400 mg.

While much has been done in the study of the cholesterol content of the blood by Herrmann Neuman,

Skimons, Stander, Tyler Underhill and many others I can find no work reported in which the cholesterol content of bladder bile and blood were estimated in the same patient. Therefore, in a series of twenty cases I obtained a sample of blood from the uterine incision and after the closure of the uterus a sample of bile was taken from the gallbladder by the method already referred to. While I realize that no reliable and definite conclusion can be reached from such a small series in trying to find a ratio between blood-bile cholesterol in pregnant women at term I am submitting the results for discussion.

It will be seen in table 2 that in eight cases (40 per cent) the blood-bile cholesterol ratio was 1:1. In another eight cases (40 per cent) the ratio was 1:2. In one case (5 per cent) the ratio was 1:3. In two cases (10 per cent) the ratio was 1:4. In one case (5 per cent) the ratio was 1:5. I am continuing this investigation as a joint effort with Dr. I. S. Ravdin and his associates from the department of surgical research of the University of Pennsylvania. Through the courtesy of Dr. R. Franklin Carter of the New York Post Graduate Hospital, fifty-eight specimens were analyzed and for the analysis and aid in interpretation of these cases I am indebted to Dr. Bernard Maraffino of the same hospital.

Of these fifty-eight cases, 60 per cent showed cholesterol concentrations between 100 and 400 mg per hundred cubic centimeters (table 5), 66 per cent of the cases showed bile salt concentrations between 300 and 400 mg (table 4).

There are many theories and data in the literature concerning the etiology of gallstones. One of the most recent theories is that of Andrews, Schoenheimer and Hrdina.¹¹ Their main contention is that gallstones

(human) with very few exceptions are composed for the main part of cholesterol and that cholesterol precipitation is caused by a lowering of the bile salt content of the bile. They believe that the cholesterol is held in solution by the bile salts in a series of loose and firm chemical complexes. Any change in the salt:cholesterol ratio, which they consider is at the level of 20 in normal man, will precipitate cholesterol. Neuman¹² believes that the normal bile salt:cholesterol ratio is 18. Walsh¹³ came to the conclusion while dissolving human gallstones in the gallbladders of dogs that the solubility of cholesterol in bile depends on an interrelationship between fatty substances, bile salts or acids and cholesterol. Altering the concentration of any one of these alters the ability of bile to hold cholesterol in an aqueous solution.

Ravdin, Riegel, Johnston and Morrison¹⁴ present evidence that, while a change in the bile salt:cholesterol ratio may be a factor in gallstone formation, it is not the sole factor.

In my first series of fifty-eight cases, the figures are surprisingly low. As will be noted, the bile:cholesterol ratio varies from one to seventeen (tables 3 and 6). In 62 per cent of the cases the ratio of bile salts to cholesterol was between 1 and 3, and in 7 per cent of the cases the ratio was reversed (1:2 and 1:3, tables 3 and 6). In discussing these observations, Dr. Ravdin was impressed with the very low bile salt concentrations as the most outstanding fact of this paper. He stated that the concentrations were well within the range of bile salt in liver bile and similar to those found in gallbladder bile from a damaged bladder. These specimens, however, were taken from the gallbladders of sup-

incorrect in their assumption that cholesterol precipitation is caused by the lowering of the bile salt content of the bile. There must be some other etiologic factor in stone formation, for none of these fifty-eight cases showed biliary symptoms or palpable stones.

Dr Charles G Johnston¹⁵ of the surgical research department of the University of Pennsylvania School of Medicine expressed surprise that calcium bilirubinate was present on microscopic examination in so few of these cases, since most specimens of duodenal drainage at least develop calcium bilirubinate appearing material

* Of the total of fifty-eight cases fifteen showed no crystals (calcium bilirubinate and cholesterol) in fifteen cases the cholesterol was under 300 mg per hundred cubic centimeters. All the cases in which the cholesterol concentration was over 300 mg per hundred cubic centimeters showed crystals calcium bilirubinate and cholesterol.

from standing (table 3). I cannot interpret these microscopic observations, because it is true that these specimens were examined after they had been standing a long time.

Twenty-four cases, or about 41 per cent, showed some degree of amylase activity (fourteen having a trace), of the six cases in the group which had a cholesterol concentration of over 500 mg per hundred cubic centimeters, only one (16 per cent) showed definite amylase activity (table 3). Of the fifty-two cases in which cholesterol concentration was under 500 mg per hundred cubic centimeters, nine showed definite amylase activity (17 per cent).

In another series of fifty-five cases studied, only twelve cases showed some degree of amylase activity (20 per cent). This low figure might be explained by the fact that these specimens were not examined for a long time after the laboratory received them. Six cases (four showing only a trace) were in the group in which cholesterol concentration was over 500 mg per hundred cubic centimeters. The remaining six cases (cholesterol concentration under 500 mg per hundred cubic centimeters) showed greater amylase activity (table 9).

Five cases showed positive cultures (two *Bacillus coli*), all these cases showed cholesterol concentrations under 300 mg per hundred cubic centimeters, three of them showed definite amylase activity. All the cases in this group with cholesterol concentrations over 300 mg per hundred cubic centimeters were negative in culture. In four of the positive cases there were crystals (table 3).

SUMMARY OF CHEMICAL ANALYSIS OF DATA

1 Sixty per cent of these cases gave cholesterol concentrations between 100 and 400 mg per hundred cubic centimeters.

2 Sixty-six per cent gave bile salt concentrations between 300 and 400 mg per hundred cubic centimeters.

3 Sixty-two per cent gave a bile salt cholesterol ratio between 1 1 and 3 1. In 7 per cent the ratio was reversed (1 2, 1 3).

4 The greater the concentration of cholesterol, the greater the number and more constant was the presence of calcium bilirubin and cholesterol crystals.

5 There was no definite relationship between the bile salt cholesterol ratio and the number and constancy of the crystals found.

6 Only 26 per cent of these cases showed no evidence of cholesterol or calcium bilirubin crystals. In all these cases cholesterol was below 300 mg per hundred cubic centimeters. All the cases in which the cholesterol concentrations were over 300 mg per hundred cubic centimeters showed cholesterol or calcium bilirubin crystals or both.

7 Thirty-six cases from a group of 113 cases studied (31 per cent) showed some degree of amylase activity. There seemed to be no definite relation between amylase activity and cholesterol concentration, although greater amylase activity was noted in cholesterol concentrations under 500 mg per hundred cubic centimeters.

8 The five cases in which positive cultures were obtained all showed a cholesterol concentration under 300 mg per hundred cubic centimeters. All the cases in which there were cholesterol concentrations over 300 mg per hundred cubic centimeters apparently gave negative results on culture.

9 Four of the five cases in which there were positive cultures showed cholesterol or calcium bilirubin crystals or both, only one case showing no crystals.

10 In a series of twenty cases the blood-bile cholesterol ratio was 1 1, in eight cases (40 per cent) 1 2, in eight cases (40 per cent), in one case 1 3 (5 per cent), in two cases 1 4 (10 per cent), in one case 1 5 (5 per cent).

GENERAL CONCLUSIONS

1 The majority (75 per cent) of normal gallbladders during pregnancy, at term, are distended.

2 Appropriate intake of fat during the antepartum period would seem advisable as a preventative of gallbladder distress, provided no previous cholecystitis exists.

3 Stasis of bile in gallbladders of pregnant women at term is common.

4 Bacterial invasion of the gallbladder bile during pregnancy at term is rare.

TABLE 9—Cholesterol Content

325	19
175	Trace
335	32
325	33
450	26
230	14

5 Metabolic dysfunction associated with functional motor disturbance and stasis rather than infection or mechanical pressure would seem to be the forerunner of biliary disease in women.

6 Hypercholesterolemia exists in pregnancy at term.

7 No definite harm was done to our patients by our investigation.

8 Clinically, postoperative nausea and vomiting were markedly reduced by release of the intra gallbladder pressure.

9 No definite ratio between the blood-bile cholesterol concentrations was demonstrated.

10 More study and more exact methods are required for better understanding of the bile and gallbladder during pregnancy.

INCREASED CARBON DIOXIDE TENSION

AS AN AID IN THE PRIMARY ISOLATION OF
CERTAIN (MEPHITIC) PATHOGENIC
BACTERIA

ROBERT N NYE, MD

AND

MARION E LAMB

BOSTON

The importance of an increased amount of carbon dioxide in the air in contact with primary cultures of certain pathogenic micro-organisms has been known for a good many years. Cohen and Fleming¹ employed this method, with associated *Bacillus subtilis* cultures, in isolating meningococci, but regarded their success as due to the reduction in oxygen tension. Chapin² obtained much better growths of primary cultures of gonococci by increasing the carbon dioxide content of the air to 10 per cent. Bang³ carried out a series of experiments on the effects of varying carbon dioxide and oxygen tensions on the growth of *Brucella abortus* but came to the conclusion that the latter rather than the former, was the governing factor. A good many years later Huddleson⁴ definitely established the importance of increased carbon dioxide tension for the growth of recently isolated strains of *Brucella abortus* but he believed that his optimum concentration, 10 per cent, created the most favorable hydrogen ion concentration for growth. Smith⁵ conclusively proved that a carbon dioxide concentration of from 0.25 to 10 per cent in the confined air is absolutely essential for the unrestricted growth of freshly isolated strains of *Brucella abortus*, that the moisture in the closed jar is only a contributing factor, and that changes in oxygen tension and hydrogen ion concentration within fairly wide limits have little, if any, effect on growth. With freshly isolated cultures of *Haverhillia multiformis*, Parker and Hudson⁶ stated that "on a solid medium the most favorable growth is obtained in a sealed jar in which a candle has been burned."

Recent work by Gladstone, Fildes and Richardson⁷ has shown that the presence of carbon dioxide in a medium is a prerequisite for the growth of all bacteria examined. There is no doubt, however, that some of the more fastidious pathogenic bacteria, when freshly isolated, resent even the atmospheric concentration of carbon dioxide. This is not to be wondered at, for during their existence in the animal body they are accustomed to a free carbon dioxide concentration of approximately 4 per cent. The importance of slight increases in carbon dioxide tension was foreseen by Smith,⁵ who made the statement over ten years ago that, if further study should prove that other pathogenic types share the carbon dioxide requirements of *Brucella abortus* the isolation and early cultivation of such types should be greatly promoted by its use.

Thompson⁸ has recently described a simple method for supplying carbon dioxide in jars for the primary culture of gonococci and meningococci. This depends on the addition of sulfuric acid to the proper amount of sodium bicarbonate in solution, both contained within the jar.

The candle jar devised by Parker and Hudson⁶ is even simpler and has been used for several years in this laboratory for the routine incubation of blood culture flasks and petri dish subcultures from cases in which *Brucella abortus*, *Brucella melitensis* or *Haverhillia multiformis* has been suspected as the etiologic factor. The jars are ordinary museum jars, approximately 15 cm in diameter and 30 cm high. A candle 8 or 10 cm long is placed in the bottom at one side, the flasks and petri dishes are placed in the jar, the candle is lighted and the cover is fitted on top. The candle flame dies out within ten or twenty seconds. Plasticine serves as a seal, except in jars in which the joint has been reground and where stopcock grease is sufficient. This simple procedure produces an atmosphere which contains from 1.5 to 3.5 per cent of carbon dioxide as shown in the table. These concentrations are well within the low and high optimums established by Smith⁵ for *Brucella abortus*, which is probably as fastidious as any of these bacteria. Incubation for forty-eight hours results in little change in carbon dioxide concentration. In jars filled with actively growing cultures of the more easily grown bacteria there

Percentage of Carbon Dioxide and of Oxygen

	Before Incubation	After 48 Hours Incubation
Small candle jar (12 by 20 cm)		
Percentage of carbon dioxide	1.74	1.83
Percentage of oxygen	17.87	18.00
Large candle jar (15 by 30 cm)		
Percentage of carbon dioxide	2.01	3.08
Percentage of oxygen	16.76	16.56

should be an increase in carbon dioxide concentration, owing to the respiration and metabolic activities of the organisms.

Identical results can be obtained by flushing out sealed jars with compressed gas mixtures containing the desired amount of carbon dioxide. The accuracy of such a procedure would be desirable in investigative work, but the optimum range of carbon dioxide concentration is so broad that the expense of the necessary equipment is not warranted in a routine bacteriologic laboratory.

For the past year jars of this sort have been used for the primary isolation of many of the bacteria encountered in the routine hospital work. Primary cultures on sheep's blood agar plates of spinal and joint fluids containing, respectively meningococci and gonococci show profuse growth after twenty-four hours' incubation and the colonies are often 3 to 4 mm in diameter. Foul smelling purulent fluids, which show short chains of small gram-positive cocci on smears from the original fluid or from a blood broth subculture, but which show no growth on an ordinary blood agar plate, yield abundant growth of alpha or beta hemolytic streptococci when the blood agar plates are placed in a candle jar.

To emphasize the importance of this method, the following is a list of routine bacteriologic specimens submitted to this laboratory during July 1935 for

which the candle jar was necessary for the process of identification

1 Pus from abscess of buttock Gram-positive cocci in pairs and short chains in blood broth No growth on blood agar plate Subculture from blood broth to candle jar blood agar plate yielded many very large flat alpha hemolytic colonies (pneumococcus type VIII)

2 Blood culture Gram positive diplococci No growth on subculture to blood agar plate Subculture to candle jar blood agar plate yielded many small alpha hemolytic colonies (Streptococcus viridans)

3 Pus from appendix abscess Gram-positive cocci in pairs and short chains in blood broth No growth on blood agar plate Subculture from blood broth to candle jar blood agar plate yielded many large gray alpha hemolytic colonies (streptococcus with alpha hemolysis)

4 Spinal fluid Gram-negative biscuit-shaped diplococci in blood broth No growth on blood agar plate Subculture from blood broth to candle jar blood agar plate yielded many very large gray translucent colonies (meningococcus)

5 Pus from tubo-ovarian abscess As before (gonococcus)

6 Fluid from knee joint As before (gonococcus)

7 Blood culture Very small gram-negative bacilli in blood broth No growth on blood agar plate Subculture from blood broth to candle blood agar plate eventually yielded numerous small pin-point colonies (unidentified gram negative bacillus *)

As this requirement seems to be a fairly constant cultural characteristic of certain bacteria, it is suggested that the condition be termed "mephitibiosis" and that the capacity of growing under such a condition be expressed by the adjective "mephitibic" The first member is derived from the noun 'mephitis' meaning foul or contaminated air "Mephitic air" is an old term for carbon dioxide

ACTIVE IMMUNIZATION TO SCARLET FEVER WITH LESS REACTION

BENJAMIN RAPPAPORT, MD
EVANSTON, ILL

At the Evanston Hospital we have adopted the procedure of testing the nurses, when they enter training, for immunity to scarlet fever by means of the Dick test, and actively immunizing those giving a positive test by subcutaneous injections of the scarlet fever streptococcus toxin

From March 1924 to October 1935 as shown in table 1, 439 nurses were tested and of this number 249, or 56.7 per cent, showed a positive Dick test and were given the injections of scarlet fever streptococcus toxin used to produce an active immunity

The amount of toxin used to produce this immunity was gradually increased, by the Dicks, to a total of 115,500 skin test doses divided as follows first dose 500 skin test doses, second dose 2,000, third dose 8,000, fourth dose 25,000, fifth dose 80,000 The second dose has four times the amount of toxin contained in the first the third dose has four times the amount of toxin contained in the second, the fourth three and one-eighth times the amount of toxin in the third and the fifth three and one-fifth times the amount of toxin in the fourth

When the injections of toxin were given as outlined the number and severity of the reactions increased markedly as compared with the smaller dosage previously used This is shown in table 2 As shown in

9 This is the fourth time a bacillus of this sort has been isolated from blood cultures in a little over a year All have been from gynecologic or obstetric cases in which fever followed operation or delivery One of these strains has been subcultured for over a year but still refuses to grow on an ordinary blood agar plate

From the Pediatric Division of the Department of Medicine of the Evanston Hospital and Northwestern University

table 3, the reactions were manifested by general malaise, chills, headache sore throat, backache, body aches, nausea, rash, fever, vomiting, painful local reactions, diarrhea, weakness and stiff and painful joints occurring separately or in various combinations It seemed to us that the large number of reactions was due possibly to the large increase in the amount of toxin in each succeeding dose over that contained in the

TABLE 1—Number of Nurses by Class Years the Number Tested, and the Results of the Dick Test Made When They Entered Training

1936	31	31	12	19
1937	39	39	20	19

preceding one In an attempt to avoid these unpleasant reactions, some of the usual doses of toxin were divided and the increase in the amount of toxin in each succeeding dose was made more gradually Beginning with the class of 1933, the splitting of some of the usual doses, especially the third dose of 8,000 skin test doses, reduced the reactions to 60.8 per cent of those receiving the toxin With the class of 1934, further division of the usual doses produced reactions in 54.5 per cent of those injected

Believing that further improvement in the method was possible, the following modification for actively immunizing against scarlet fever was adopted for the average case, beginning with the class of 1935 first dose 150 skin test doses, second dose 300 third dose 600, fourth dose 1,200 fifth dose 2,500 sixth dose 5,000, seventh dose 10,000, eighth dose 20,000, ninth

TABLE 2—Number and Percentage of Nurses Developing Reactions After the Injections of Toxin in Conjunction with the Method Used

Class Year	Number of Nurses Receiving Injections	Number Showing Reactions After Injections	Percentage of Nurses Showing Reactions	Method Used
1926	25	3	12.0	That advocated by the Dicks
1927	16	1	6.2	That advocated by the Dicks

1929	20	3	15.0	That advocated by the Dicks
1930	24	9	37.5	That advocated by the Dicks
1931	15	12	80.0	That advocated by the Dicks
1932	21	21	100.0	That advocated by the Dicks
1933	23	14	60.8	Began splitting some of the doses
1934	22	12	54.5	Divided a larger number of the doses
1935	19	5	26.3	Our modification with 10 doses
1936	19	2	10.5	Our modification with 10 doses
1937	19	3	15.7	Our modification with 10 doses

dose 40,000, tenth dose 80,000 This makes a total of 159,750 skin test doses, which is 38.3 per cent more toxin than is given by the injection of the usual five doses With this modification, 26.3 per cent of those receiving the toxin developed reactions in the class of 1935, 10.5 per cent in the class of 1936 and 15.7 per cent in the class of 1937 The number of reactions during the past three years was greatly reduced and the few reactions that did occur were of such a mild nature that very little time was lost off duty We believe that

this improvement was due to the more gradual approach to the final dose of 80,000 skin test doses

In our modification the individual is actively immunized by a series of ten injections of the scarlet fever streptococcus toxin. The initial dose is 150 skin test doses and at weekly intervals the amount of toxin in each successive dose is doubled, with the exception of the fifth injection. Whenever reactions occurred, the succeeding dose was increased only 50 per cent or even less to avoid such occurrences. Later, in some of these cases the doses could again be increased 100 per cent. In some cases less reaction occurred when the injections were given at intervals of two weeks. In this way the nurses were immunized with a minimum of disturbance

the modification described 100 per cent of those injected in the class of 1935 were rendered Dick negative after the first set of injections. In the class of 1936 with the same method the percentage was 78.9, and in the class of 1937 again with the same procedure the percentage was 84.2. As is well known, some individuals develop their immunity with more difficulty than others. For the thirteen classes under consideration with a total of 249 nurses receiving these injections of toxin, 184, or 73.8 per cent, showed a negative Dick test after the first set of injections were completed and sixty-five nurses, or 26.2 per cent were Dick positive. After receiving extra injections of the toxin, thirty-eight nurses of the latter group became negative to the

TABLE 3—*Various Symptoms of the Reactions and How They Increased in Number**

* The number and percentage that were made Dick negative after the first set of injections of the toxin was completed the number who after extra injections of the toxin became Dick negative and the total percentage made negative to the Dick test. Beginning with the class of 1933 this table also shows the number of nurses who were again Dick tested one year after being actively immunized and the number and percentage that retained their immunity as shown by this retest

or loss of time off duty. The final injection is 80,000 skin test doses.

Previous to the use of this modification 80 per cent of the nurses in the class of 1931, and 100 per cent of those in the class of 1932 receiving the usual injections of toxin in the five doses, developed reactions. This was manifested in some by only one symptom, such as headache or vomiting, in others by sore throat, vomiting, rash, joint pains or other conditions in various combinations.

To determine the effectiveness of this modification as compared to the usual method of five injections the Dick test was repeated a few weeks after the last dose of 80,000 skin test doses was given. As will be noted in table 4, 40 per cent in the class of 1929 were rendered Dick negative after the first set of injections. However, at this time the amount of toxin injected was less than is now given in the usual five injections. With

Dick test. This increased the number actively immunized as shown in table 4, to a total of 222 nurses or 89.1 per cent.

For the nurses in the classes of 1925 and 1926 the records are incomplete and the results are not known for eleven nurses. Since that time fifteen nurses of those showing a positive Dick test after the first set of injections dropped out of training before their active immunity could be completed. By subtracting these twenty-six from the 249 nurses there remain 223 nurses with complete records as shown in table 5. Of this number 222, or 99.5 per cent were completely immunized as shown by a negative Dick test. The exception was one nurse of the class of 1934, who was sick in bed for two weeks after an injection of 8,000 skin test doses. Another attempt to immunize this nurse resulted in an illness of several days' duration and further attempts were abandoned.

With the idea of determining the duration of the immunity to scarlet fever produced by the injections of toxin, one year after these nurses were actively immunized they were retested by classes with another Dick test. This retest was initiated in 1931 with the class of 1933. Of the members of this class as shown by table 4 73.9 per cent retained sufficient immunity after one year to give a negative Dick test. 73.9 per cent in the class of 1934, 89.9 per cent in the class of 1935 and 100 per cent in the class of 1936 were negative to this test. At the present time it is too early to carry out this procedure with the class of 1937. It may be possible that with the increase in the total amount of toxin injected with this modification the resulting immunity to scarlet fever, as shown by a negative Dick test, will be more lasting in a larger number of individuals. This can be determined only with further study.

To determine the effectiveness of the active immunization as described in preventing an individual from actually developing scarlet fever, I have looked through the records and found that since 1920 ten student nurses have contracted scarlet fever while in training. These occurred as follows: two in 1921, one in 1922, two in 1923, one in 1924, three in 1925 and one in March 1926. The first six of these cases of scarlet fever occurred before the Dick test was adopted. The result of the Dick tests for the next three cases was not recorded. The last mentioned nurse had a positive Dick test on entering training and after the first set of injections the Dick test was again positive. This was followed by additional injections of toxin. After these had been given, the Dick test was repeated and was positive.

TABLE 5—Number Actively Immunized as Shown by a Negative Dick Test

Class Year	Corrected Number of Initial Positive Dick Tests	Number Eventually Made Dick Negative	Per Cent Rendered Dick Negative	Comment
1925	4*	4	100	
1926	1,*	17	100	
1927	14†	14	100	
1928	13†	13	100	
1929	10†	10	100	
1930	24	24	100	
1931	10	10	100	
1932	21	21	100	
1933	23	23	100	
1934	22	21	95.4	1 reacted severely
1935	19	19	100	
1936	19	19	100	
1937	17†	17	100	

* This number was obtained by subtracting the number of nurses having incomplete records from the number showing a positive Dick test at the time they entered training.

† This number was obtained by subtracting the number of nurses who dropped out of training before their immunization was complete from the number showing a positive Dick test when they entered training.

Since March 1926 no student nurse has developed scarlet fever, although the care of patients with scarlet fever is included in their course of training. It would appear that the determination of immunity to scarlet fever by means of the Dick test and active immunization of the susceptible individuals are of definite value. Many have raised the objection that active immunization is accompanied by a large number of reactions. I am herewith presenting a method that I believe will make possible this active immunization with a minimum number of reactions.

CONCLUSION

By means of a more gradual approach to the final dose of 80,000 skin test doses, the active immunization with the scarlet fever streptococcus toxin can be accomplished with a marked reduction in the number and severity of these reactions.

708 Church Street

TULAREMIA

REVIEW OF LITERATURE OF CASES CONTRACTED BY INGESTION OF RABBIT AND THE REPORT OF ADDITIONAL CASES WITH A NECROPSY

HAROLD L. AMOSS, M.D.
AND
DOUGLAS H. SPRUNT, M.D.
DURHAM, N. C.

Francis,¹ in reviewing the modes of infection with *Bacterium tularensis*, notes three reports of infection through the ingestion of uncooked or partially cooked rabbit. One of these instances was reported by Freese, Lake and Francis,² one by Crawford,³ and the third report is ours. It is our intention in this paper to report in detail the two cases that have come under our observation.

LITERATURE

Since the time of the report by Francis, Beck and Merkel⁴ have added an instance of an infection of this nature. The report by Beck and Merkel is the only report of this nature in which necropsy data are given.

Crawford³ reports an instance in which seven members of a family had the disease. The father and grandmother were not affected. The children found a dead rabbit, which they cleaned, cooked and served for an evening meal. When first seen by the physician four days later they staggered about, vomited and complained of pain. There were no ulcers or skin involvement. They all had temperatures between 103 and 105 F., and two died. Five whose blood was examined showed agglutinins for *Bacterium tularensis* in dilutions of 1:320, 1:640, 1:1,280, 1:2,560 and 1:2,560. Submaxillary nodes were enlarged in some, but no lymph nodes elsewhere were affected and only one patient had conjunctivitis.

Freese, Lake and Francis² described four cases with three deaths in a family after eating a rabbit that was killed by a dog. The onset in all cases was sudden. In one there were nausea, headaches and chills. Three patients vomited and one had convulsions. Within twenty-four hours after onset the axillary temperature was between 103 and 104 F. Conjunctivitis and swelling of the lymph nodes were present. Washings made from swabs of the nose and throat produced tularemia in a guinea-pig. Necropsies were not permitted.

Beck and Merkel's⁴ case was that of a man, aged 61, having a low basal metabolic rate and occasional glycosuria. After shooting a rabbit and dressing it, he ate some of the partially cooked rabbit. The next day he

felt sick and had an insatiable thirst. All the initial symptoms became gradually worse; he became profoundly toxemic, and a low muttering delirium developed. The temperature reached 105 F on the fifth day. Physical examination showed no cutaneous lesions and no enlargement of the superficial lymph nodes. The liver extended four fingerbreadths below the costal margin and the spleen was just palpable.

The lungs were clear except for some dulness over the left base posteriorly. The white count rose from 6,325, 88 per cent of the leukocytes being polymorphonuclear cells, to 21,250, 66 per cent of the leukocytes being polymorphonuclear cells. The blood sugar was 140 mg per hundred cubic centimeters. The stools were positive for occult blood.

At necropsy the viscera were edematous and congested. The mesenteric and epigastric lymph nodes as well as those along the diaphragm and head of the pancreas were enlarged and contained large areas of necrosis. The liver was studded with discrete yellowish gray areas. The spleen was enlarged, and areas of necrosis were found. Small ulcers were found in the stomach and ileum. The liver and pancreas showed hemorrhagic necrosis. In the lungs there were no lesions except infarcts. Guinea-pigs injected with the tissues developed tularemia.

REPORT OF CASES

CASE 1—History.—A white man, aged 44, was admitted to the Duke Hospital Nov. 3, 1932, with delirium and a high fever.

One week before admission the patient, after having consumed a large quantity of whisky over a period of several days, went hunting with a Negro (patient 2). They killed a rabbit, which they cleaned, cooked and ate. No information could be obtained as to the condition of the rabbit when it was killed or as to how it was killed. It is presumed that the rabbit was not well cooked. About eight hours later the patient complained of pain in the left side of the chest, became feverish and had a severe chill. On the following day a profuse diarrhea without blood or mucus ensued, and the fever continued. Three days later he became stuporous and irrational.

On admission to the hospital the temperature was 40.3 C (104.5 F), the pulse 120 per minute, respirations 32 per minute, and blood pressure 120 mm of mercury systolic, 80 diastolic. The patient was well developed. Respiration was rapid and there was an expiratory grunt. The accessory muscles of respiration were not used. He was comatose and the skin had a peculiar dusky red color. The pupils were contracted and did not react to light. The lungs were resonant throughout. There were areas of tubular breathing and very coarse bubbling rales, which appeared and disappeared, owing apparently to the large quantity of mucus that obstructed the bronchi. The other observations were unessential. The red blood cell count was 4,300,000, hemoglobin 12.5 Gm, mean hemoglobin content 29.8×10^{-1} Gm. The white blood count was 9,300, 77 per cent of the leukocytes being polymorphonuclears. The blood Wassermann reaction was negative. The carbon dioxide combining power of the blood was 46.6 volumes per cent. The blood sugar was 113 mg per hundred cubic centimeters and the non-protein nitrogen of the blood 42 mg. Agglutination for *Bacterium tularensis* was positive in a 1:640 dilution of serum.

Course in the Hospital.—The patient's high temperature of 40.3 C was maintained until his death six days after admission and thirteen days after the onset of the disease. The pulse rate was relatively slow, ranging between 110 and 130. The respirations during the first four days ranged between 26 and 40. Tachypnea and dyspnea were marked during the last three days. On the morning of his death there were dulness and suppression of breath sounds at the right base. He became more and more cyanotic, and death occurred on the thirteenth day of illness.

Necropsy.—This was performed three hours after death. The body was warm. No cutaneous lesions were found. The superficial lymph nodes were not palpable. The peritoneal

surfaces were smooth and glistening. The liver extended about 3 cm below the costal margin. Both pleural cavities were filled with a yellow opaque material. At the point of the bifurcation of the trachea there was a large mass of lymphoid tissue about 10 cm in diameter and about 6 cm in length completely encircling the trachea and bronchi. On section it was seen to be composed of a large amount of necrotic and lymphoid tissue. This mass constricted the trachea and bronchi to about one third of its usual diameter. The pleural surfaces of the lungs were smooth and glistening. In the posterior portion of the right lower lobe was a firm mass measuring about 7 by 6 by 6 cm. On section this mass was necrotic. Nothing was seen in cross section of the remainder of the lung except extensive pulmonary edema and congestion. The bronchial mucosa was red. No ulcers were found in either the stomach or the intestine. The lymph nodes in the mesentery were not enlarged and showed no areas of necrosis. Examination of the kidneys, adrenals, heart, liver, pelvic organs, structures of the neck and bone marrow revealed no gross abnormalities.

Microscopic preparations made from the caseous portions of the lungs showed almost complete destruction of the usual lung architecture and replacement by a mass of debris composed of nuclear remnants, fibrin, and amorphous pink-staining material. Some fairly well preserved cells with pyknotic nuclei were seen. Sections taken from other portions of the lung revealed an interstitial pneumonia. The predominating cells were mononuclear, although some polymorphonuclear cells were seen. The mononuclear cells appeared to be of three types: lymphocytes, plasma cells and monocytes. Some mitotic figures were seen in these cells. The alveoli contained numerous macrophages, which had engulfed considerable debris. No thrombi and no endothelial proliferation were seen in the blood vessels. The lumen of the bronchi were filled as a rule with a large number of polymorphonuclear leukocytes. The splenic pulp was markedly congested and there was some increase in the white cell elements, with an occasional mitotic figure. The malpighian corpuscles were quite large and an occasional one showed a small area of necrosis, however the characteristic feature of the spleen was the presence of numerous focal areas of necrosis which had no relation to the malpighian corpuscles. Scattered through the liver were seen numerous focal areas composed of small cells, which resembled Kupffer's cells. Intermixed with these were some pyknotic nuclei and what appeared to be cytoplasmic debris. A microscopic preparation of a hilar lymph node revealed large focal areas of necrosis scattered throughout the node. These areas appeared to have no definite position with regard to the structure of the node. They resembled tuberculous areas of necrosis except that there were no giant cells. The sinuses were packed with a large number of macrophages and considerable pigment. This pigment was probably from the lungs, as none was seen in sections of a node removed from the abdomen. A microscopic preparation of a lymph node removed from the hilus of the liver showed several extensive areas of necrosis but no giant cell formation. The sinuses contained a large number of mononuclear cells. The testes showed an absence of spermatogenesis. The nuclei of the cells lining the seminiferous tubules had undergone either pyknosis or karyorrhexis. The interstitial tissue was infiltrated with a few plasma cells. Sections of the pancreas, kidney, adrenal and bone marrow showed no changes of note.

Cultures of the blood, lymph nodes, spleen and testes were taken both on cystine agar and on the usual mediums without obtaining *Bacterium tularensis*. A guinea-pig was injected with material from the lung and spleen. The animal died within twenty-four hours of a staphylococcal infection. Two additional guinea-pigs injected with blood and testicle show no evidence of tularemia either clinically or at necropsy.

The anatomic diagnosis was tularemia, focal necrosis in lymph nodes, spleen and lung, focal round cell accumulation in liver, interstitial monocyctic pneumonia, lobular pneumonia, pulmonary emphysema.

CASE 2—History.—A Negro farmer, aged 31, was admitted to Duke Hospital Nov. 3, 1932, in a lethargic condition. On the night of the hunting trip with patient 1 he was nauseated, vomited, and complained of abdominal soreness. He also had a chill and felt feverish. He had been weak since the onset

and had remained in bed. He had been frequently delirious and there had been some anorexia. November 1 there was another chill. There had been no cough or sputum since the onset of the disease. There was no history of a bloody diarrhea.

Examination—On admission to the hospital the temperature was 39.8 C (103.6 F), pulse 120 per minute, respirations 32 per minute and blood pressure 152 mm of mercury systolic 110 diastolic. The skin was dry and hot. There was a coarse tremor of the tongue. The diaphragm was high on both sides, and there was a lag of the lower chest of the left side anteriorly. The breath sounds were harsh, with prolongation of expiration over the left side of the chest below the angle of the scapula. The breath sounds were suppressed at the left base posteriorly. There was a coarse tremor of the fingers of both hands. The upper reflexes were hypo-active, and knee and ankle jerks were absent. The red blood count was 4,300,000 and the hemoglobin was 137 Gm. The white blood count was 11,850, 76 per cent of the leukocytes being polymorphonuclears. The blood Wassermann reaction was negative. Repeated agglutination of the blood was negative for *Bacterium tularensis*. The direct van den Bergh reaction was 27 mg. The blood nonprotein nitrogen was 120 mg. per hundred cubic centimeters. A blood culture was sterile and an examination of the spinal fluid showed no abnormalities. The urine had 3 plus albumin and many granular casts and leukocytes. The carbon dioxide combining power was 35.3 volumes per cent.

Course in the Hospital—The temperature remained elevated above 40 C (104 F), with a parallel elevation of pulse and respiratory rates. The patient's lethargy finally deepened, and he died on the twelfth day after the onset and the fourth day in the hospital.

Necropsy was denied, but because of the history, the similarity with case 1, and the absence of physical signs to explain the morbid state, the diagnosis of tularemia was made.

COMMENT

Although we cannot prove that the rabbit eaten by the two persons whose cases we have reported had tularemia, it seems likely that the rabbit was weak at the time it was killed, as the hunters were probably too intoxicated to shoot a well rabbit. It is also likely that the animal was not thoroughly cooked, and Francis¹ has shown that the organisms may withstand some cooking and still be infective.

The mode of entry of the organism may have been through the intact skin, but it seems likely that the alimentary canal was the mode of entry. This is borne out by the fact that a lymph node from the hilus of the liver as well as the liver itself showed definite evidence of tularemic infection.

A diagnosis of systemic infection with tularemia was made in both cases because of the high fever, delirium and typhoid state without physical signs. Such a diagnosis led to the agglutination tests and to more detailed histories. The agglutination test in case 1 and the history of the ingestion of rabbit meat appear to confirm the tentative diagnosis. Of especial interest is the fact that in the two cases of strikingly similar courses only one showed a positive agglutination to *Bacterium tularensis*. This is not an unusual observation in typhoid.

It is interesting that no definite ulceration was found in the intestine as in the case of Beck and Merkel.⁴ It does not, however, seem unlikely that the tularemia organisms can pass through the intact intestinal mucosa, as they have the ability to pass through the skin.

Vagal Inhibition—Ventricular slowing for a short period is certainly produced by vagal inhibition; this inhibition is a common occurrence for it is the main cause of fainting attacks.—Dr. Maurice Campbell, F.R.C.P., quoted by Fisher, Alexander. *Aphorisms in Clinical Medicine*, *Canad. J. Med. & Surg.* 77:166 (June) 1935.

ACUTE, FATAL CORONARY INSUFFICIENCY

ROBERT L. LEVY, M.D.

AND

HOWARD G. BRUENN, M.D.

NEW YORK

Any person with disease of the coronary arteries may die suddenly. By sudden cardiac death is meant cessation of the heart beat within a few minutes after the onset of acute failure and at a moment when its occurrence was not anticipated. The event does not permit of more precise definition. In a recent compilation of statistics Hamman¹ found that 91 per cent of sudden deaths from natural causes result from diseases of the cardiovascular system, and that of deaths from sudden heart failure 65 per cent are due to disorders of the coronary arteries.

In a majority of instances, disease of the coronary arteries may be recognized clinically. Occasionally, no symptoms or signs are present. More often, when an unexpected attack as of pain or pulmonary edema appears to be the first evidence of disturbance, it is found on more careful inquiry that previous complaints of discomfort were present which were not regarded as having their source of origin in the heart. If an adult, either supposedly in good health or one who has suffered from anginal pain, suddenly falls dead, it is generally assumed that thrombotic occlusion of a coronary artery has occurred. Any acute episode observed in a patient known to have coronary artery disease is commonly ascribed to thrombosis. It is our purpose to call attention to a group of cases not unfamiliar to the pathologist but less well known to the clinician. These patients all have atherosclerosis of the coronary arteries and die suddenly. At necropsy, no fresh occlusion is found and no other anatomic lesion is present to explain the immediate cause of death. To the syndrome may be applied the designation "acute, fatal coronary insufficiency."

MATERIAL

The material was collected from the files of the department of pathology.² All cases of syphilitic aortitis, as well as those in which a complicating condition was present that might have been partly responsible for death, were excluded.³ As a result of this procedure, the number of protocols available was considerably reduced and the records of twenty-four patients with atherosclerosis of the coronary arteries form the basis of this presentation. Three hundred and fifty-two other cases of coronary sclerosis, with and without thrombosis, serve as background for comparison. It must be borne in mind that, with two exceptions (table 1), the patients were sick enough to seek relief in the hospital. Study of a group of ambulatory cases, such as are seen, for example, by the medical examiner might yield somewhat different results. The clinical histories seemed adequately com-

³ Hamman, Louis. Sudden Death. *Bull. Johns Hopkins Hosp.* 55:587 (Dec.) 1934.

⁴ We are indebted to Dr. James W. Johling, director of the department of pathology, for permission to use the necropsy protocols.

⁵ In one patient aortic stenosis of unknown etiology was diagnosed clinically and found post mortem. Although this lesion predisposes to sudden death as was recently pointed out by Marvin and Sullivan (*Am. Heart J.* 10:705 [Aug.] 1935) the changes in the coronary arteries were so advanced that the case was included.

plete The hearts were examined in routine fashion, carefully but without the aid of special technics. Several blocks of tissue were removed from each specimen for microscopic study. Special stains were employed when indicated.

CLINICAL PICTURE

With one exception, the patients were 50 years of age or over. One man, aged 43, presented such a remarkable picture that a detailed account of his case will be given later. Eleven of the twenty-four patients were in the sixth decade of life, the remainder were between 60 and 80 years of age. Males predominated in a ratio of 7 to 1. This is a higher proportion of males than was found in a group of 337 patients with coronary artery disease who came to necropsy in this hospital, namely, 2 to 1.⁴ It appears that men with this condition are more likely to die suddenly than women. The ratio of white persons to Negroes was 11 to 1, the same as in the series just mentioned. Sudden death was just as common in the Negro as in the white person.

In twelve cases (50 per cent) the clinical diagnosis was erroneously given as coronary thrombosis. This is in accord with the usual practice referred to in an earlier paragraph. The remaining twelve cases were correctly diagnosed coronary sclerosis.

Four patients (16 per cent) were known to have diabetes mellitus, whereas of 297 patients with coronary

source of complaint is noteworthy, more often the heart muscle was sufficiently impaired so that congestive failure also was present. Too much stress cannot be put on this circumstance, however, since the patients under consideration were sick enough for hospitalization. Unless occlusion has occurred, sufferers from coronary disease rarely seek bed care for pain alone, they enter the hospital because of congestive failure.

Hypertension was known to have been present prior to the final admission to the hospital in ten of thirteen cases. It was observed shortly before death in eight of nineteen patients and in five cases no observations were made. A majority of the patients who died suddenly thus had an elevation of blood pressure at some time prior to their terminal illness. The lower incidence of hypertension shortly before death was in all probability due to the occurrence of cardiac insufficiency.

Electrocardiograms were taken on seventeen patients. In every instance there were deviations from the normal. Bundle branch block and a negative T wave in lead 1, or in leads 1 and 2 were observed seven times each; permanent auricular fibrillation, three times; paroxysmal auricular fibrillation, twice; complete auriculoventricular block and a prominent Q wave in lead 3, each once. Frequently a series of records was taken and in a number of such serial studies there were noted changes in the form of the ventricular complexes from day to day or from week to week, such as have been described as occurring after myocardial infarction.⁵

The manner of sudden death is given in table 1. Obviously the circumstances attending the event will vary in hospital and ambulatory patients.

PATHOLOGY

The heart was almost invariably enlarged, only four specimens weighed under 400 Gm. The range was from 280 to 860 Gm, with an average of 563 Gm.

Intracardiac thrombi were present in three of the hearts twice in the left ventricle and once each in the right ventricle and right auricle.

Infarcts of the myocardium were noted in eight cases. In four instances there were recent areas of infarction in the left ventricle, in eight, old scars were present in the left ventricle and once in the septum. In four of the hearts both recent and healed infarcts were found.

The lesions in the coronary arteries were of varying degree but in sixteen cases there were extensive calcification and stenosis of both right and left main trunks as well as of their larger branches. The changes predominated in the left anterior descending branch most frequently (twelve times). Next in order of frequency were the left circumflex, the right circumflex and the right or left main stems. In two cases the orifice of one coronary artery or of both was narrowed, though not occluded by a plaque. Curiously enough, no myocardial fibrosis, gross or microscopic, was present in four cases, in two others this was described as slight, in spite of extreme sclerosis, calcification and even complete occlusion of some vessels. The remaining eighteen hearts all showed diffuse and well marked fibrotic changes.

In none of these hearts were thrombi found in any of the branches of the coronary system. Because serial sections were not made, a categorical statement that there had not occurred recent occlusion of one or more

sclerosis in whom death was gradual, only 23 per cent had diabetes. Three of the four diabetic patients suffered from gangrene, in two a leg had been amputated and, in the third a toe. On the basis of this small material it appears that the diabetic patient with coronary sclerosis particularly if gangrene has occurred, is more likely to die suddenly than the non-diabetic patient with comparable changes in the coronary arteries. The possible relation of insulin to sudden death will be considered in the discussion.

The duration of cardiac symptoms ranged from eighteen months to twenty years, with an average of seven years. This is a relatively long duration of life after the onset of symptoms in patients with coronary sclerosis. But in striking contrast to this average is the fact that in eight cases (33 per cent) there was a history of cardiac discomfort for less than six months, suggesting that the terminal process was rapidly progressive. In one instance, that of a 50 year old diabetic Negro, with advanced coronary lesions, no symptoms referable to the heart were noted.

The symptoms and signs prior to the final attack were, in the order of frequency: pain and congestive failure combined, ten cases; congestive failure only, nine; pain only, three; and paroxysmal auricular fibrillation only, one case. A story suggestive of previous coronary occlusion was obtained in three cases. The relatively uncommon occurrence of pain as the only

of the smaller and deeper radicles is not justified. That closure of twigs may have taken place is evident from the fact that old and recent infarcts were found in four cases. It is probable, however, that these resulted from atheromatous narrowing or occlusion of the nutrient arteries rather than from blockage by thrombi.

Lesions of syphilis were not recorded in a single protocol.

ABSTRACTS OF ILLUSTRATIVE CASES

Four histories and necropsy protocols are here briefly given in order to illustrate some of the types of cases encountered.

CASE 1—J. K., a man, aged 43, was an advertising agent. The history was obtained from his wife who stated that for a week he had complained of shortness of breath and for two days of precordial pain, aggravated by effort.

On the evening of his death he and his wife were on their way home from a cinema. On the 168th Street subway station he suddenly had agonizing substernal pain and collapsed. One of the hospital residents happened to be on the platform and had him carried into the Vanderbilt Clinic. His color was ashen and cyanosis was marked. The heart sounds were barely audible and the blood pressure could not be read. He died twenty minutes after the onset of acute symptoms.

At necropsy the heart weighed 280 Gm. There was no myocardial scarring, gross or microscopic. The left coronary artery contained several small, slightly raised yellow plaques for a distance of 1 cm from its origin. At this point it bifurcated and the anterior descending branch for a distance of approximately 2 cm from the bifurcation was almost completely obliterated by an old, calcified arteriosclerotic lesion. Below this, for an equal distance the lumen was also markedly narrowed, being reduced to pinpoint size by eccentric thickening of the wall. No thrombus was present in any of the vessels. The circumflex artery contained numerous atheromatous plaques. The right coronary was narrowed considerably at its orifice, but beyond this its lumen appeared ample. At many points discrete and confluent gray and yellow plaques were present.

The myocardium of both ventricles was flabby. No infarcts were demonstrated. There was advanced arteriosclerosis of the aorta and its primary branches. Plaques in the aorta surrounded and to a considerable extent narrowed the orifice of each coronary artery.

Noteworthy in this case were the comparative youth of the patient, the short duration of symptoms, the absence of cardiac hypertrophy and, by contrast, the advanced lesions in the coronary arteries.

CASE 2—W. J., a man aged 53, a stationary fireman and dock hand, for twelve years had had dyspnea on effort and occasional abdominal pain. He was admitted to the hospital with congestive failure of marked degree. On examination the heart was large and the aorta dilated. The blood pressure ranged from 110 to 130 mm of mercury systolic and from 70 to 85 diastolic. The electrocardiogram showed a diphasic T wave in lead I, and five days before death auricular fibrillation appeared. He died suddenly one month after admission, at a time when he appeared to be improving.

At necropsy the heart weighed 600 Gm. There were a few yellow intimal plaques in both main branches of the coronary arteries as well as in the aorta. Microscopically hypertrophy of the muscle fibers was noted. In his final note Dr. A. M. Pappenheimer stated that the pathological study as far as it has been carried out, offers no explanation for the sudden death.

The symptoms in case 2 extended over a period of twelve years and the heart was greatly enlarged. Whether hypertension had previously been present is not known. The coronary lesions were minimal, no other anatomic changes were present to account for the sudden end.

CASE 3—J. F., a man aged 57, a dentist, had had symptoms of congestive failure for two years but no cardiac pain. The

heart was greatly enlarged. The blood pressure was 110 mm of mercury systolic, 90 diastolic. The electrocardiogram showed bundle branch block. He was found dead in bed early one morning.

At necropsy, the heart weighed 720 Gm. There was a small thrombus in the apex of the left ventricle, and the anterior wall of this ventricle was infarcted. About 1 cm from the orifice of the anterior descending branch of the left coronary artery was an atheromatous plaque about 3 mm in diameter which almost completely occluded its lumen. The lumen beyond this point was normal. There were a few yellowish intimal plaques in both right and left main branches.

The final pathologic note by Dr. Pappenheimer read: "A somewhat unusual case of coronary disease in which a single plaque in the descending branch of the left coronary artery led to partial occlusion. The fibrosis of the myocardium appeared to be limited to the inner strata and was accompanied by the slow development of a mural thrombus of the left ventricle and progressive cardiac failure."

CASE 4—F. H., a man, aged 54, a merchant, for twenty years had had paroxysmal cardiac pain, usually after effort. For the ten days preceding his admission to the hospital, pain had been almost continuous and he became short of breath. On examination, the heart was only slightly enlarged. Regular rhythm was interrupted by premature beats. The electrocardiogram showed bundle branch block, and the form of the complexes changed in later records. The blood pressure was from 90 to 110 mm of mercury systolic and from 66 to 86 diastolic. There was no fever. The leukocytes ranged from 15,000 to 17,000, there was well marked polynucleosis. He died in his sleep.

At necropsy the heart weighed 450 Gm. There were thrombi in the right auricle. There was a recent infarct in the left ventricle, near the septum and an old area of infarction occupying about one fourth of the anterior wall, also near the septum. Both coronary arteries and their main branches showed extensive atheroma, calcification and narrowing of their lumens. There were numerous small atheromatous ulcers in the intima. The heart muscle showed extensive necrosis, degeneration and scarring, especially marked in the left ventricle. There were infarcts in the right lung.

The long story of paroxysmal heart pain with recent acute persistent exacerbation in this case suggested the diagnosis of coronary thrombosis. The coronary lesions were advanced, indicating a progressive process over a long period of time and leading eventually to closure of portions of the coronary bed, with infarction of the myocardium and congestive failure. No thrombi were present in the coronary arteries.

COMMENT

Disease of the coronary arteries is the lesion most frequently associated with sudden cardiac death. Coronary arteriosclerosis is by far the commonest disorder of these vessels, having been found in 97 per cent of 762 proved cases.⁶ Thrombosis is to be regarded as

TABLE 2—Incidence of Sudden Death in 376 Fatal Cases of Coronary Sclerosis and Thrombosis

	Number of Cases	Sudden Death per Cent

Sclerosis without thrombosis	337	11.8
Thrombosis present	39	33.3

an episode in the course of sclerosis and is clearly not essential for sudden cardiac standstill.

The incidence of sudden death in 376 fatal cases of coronary sclerosis, with and without thrombosis is shown in table 2. Of the total series, in 14 per cent death came suddenly. But of the cases of sclerosis without thrombosis, in only 12 per cent did death occur.

⁶ Levy R. L., Bruenn H. G. and Kurtz D. Facts on Disease of the Coronary Arteries Based on a Survey of the Clinical and Pathologic Records of 762 Cases. *Am. J. M. Sc.* 187: 376 (March) 1934.

in this manner, whereas in the cases in which a thrombus was present death was sudden in 33 per cent. The occurrence of thrombosis almost tripled the likelihood of a sudden end.

Yet the notion that coronary thrombosis is the immediate cause of death in these patients is erroneous. In thirty-nine hearts in which thrombotic occlusion of

one or more coronary branches was found at necropsy, the descriptions of the thrombi were carefully scrutinized with respect to probable age. In but a single instance could the thrombus be characterized as fresh, that is, as having formed within several hours of death. The one exception was observed in a moribund, elderly man with marked secondary anemia due to a bleeding duodenal ulcer. In all the other cases the thrombus was at least several hours old. Usually the microscopic appearance indicated that it had formed at least several days before the heart ceased to beat, in many of the specimens, organization had occurred and in some canalization had already taken place. In short, thrombosis of a coronary artery is rarely, if ever, the immediate cause of sudden death. It increases the liability to sudden death by seriously reducing the functional capacity of an already impaired coronary bed.

In the light of this circumstance the question naturally arises as to how long after an attack of thrombosis patients may live. The clinical records were consulted, with a full knowledge that the description of symptoms may be misleading and that in a large number of cases the episode is asymptomatic. When recovery from a given attack did not take place, the average duration of life after the attack was two weeks in those patients who died suddenly, as against four weeks in those whose end came gradually, by progressive failure. In the group with sudden death the range in duration of life was from less than one day to fourteen months, in the gradual failure group the range was from three days to two years. It is during the first two weeks after an attack of coronary thrombosis that sudden death is most likely to occur. Rupture of the heart was not observed in any of our cases.

In the course of this study, two other factors bearing on the incidence of sudden death became apparent. These were the character of the coronary artery lesions and a previous history of anginal pain (table 3). In general the more advanced the lesion the more likely was the possibility of sudden death. But the end came quickly and unexpectedly, even in the presence of only a few intimal plaques. And in each of the anatomic groups into which the cases for purposes of analysis were arbitrarily divided, the incidence of sudden death was strikingly higher in the patients who gave a history

of pain than in those who did not. Of the total series, 14 per cent died suddenly. In the group with pain, death was sudden in 27.5 per cent, in the group without pain in only 9.1 per cent.

What is to be regarded as the mechanism of quick cardiac standstill? It is generally believed that ventricular fibrillation is the immediate precursor of sudden death. This may well be so, but it is a conclusion reached largely by inference from animal experiments, since actual graphic records of the final heart beats in man have been obtained in only a few cases.⁷ The theory of vagus inhibition, championed by Allbutt,⁸ has received but little support.

The question as to what, in a given instance, may have induced ventricular fibrillation has not been answered. Since in all the cases described the present-ing pathologic lesions were found in the coronary arteries, it seems reasonable to infer that in some way, acute coronary insufficiency was brought about and that an inadequate supply of blood to the myocardium resulted in cessation of the heart beat. That sudden closure of a coronary artery can cause the ventricles to fibrillate has been known for many years.⁹ But whether ventricular fibrillation or some other disturbance in cardiac mechanism occurred is, for the moment, of secondary importance.

In the presence of anatomically diseased coronary arteries, functional insufficiency may conceivably be brought about by throwing an added burden on the heart or by further curtailing the flow of blood through the coronary channels. In either event there results a disproportion between the amount of work that the heart is called on to perform and the quantity of blood that reaches the myocardium. The work of the heart may be increased by physical effort or by emotion.

Sudden death after sharp exertion, such as running for a train, is not an exceedingly uncommon event, in this series it is exemplified by the man who collapsed on the bedpan. Of greater popular interest is the story of the individual who drops dead following an intense emotional experience, be it joyful or painful. So, one reads of a person's unexpected death after he has learned of the passing away of a dear friend, on being reunited with a relative after years of separation or on holding a royal straight flush in a poker game. One of our patients collapsed during a church service. Those who die during sleep may experience vivid emotions in their dreams. To awaken with the heart beating forcefully and rapidly after dreaming of a fight with a robber or of an exciting chase is a sensation known to most of us. Emotion causes a discharge of epinephrine.¹⁰ Epinephrine stimulates the sympathetic nervous system and increases the work of the heart. In small doses it may cause ventricular fibrillation, in larger amounts it can arrest it.¹¹

To explain sudden death in those who fall over while sitting quietly in bed, apparently serene in spirit, it is necessary to assume the existence of a nervous mechanism for which, as yet, final proof is lacking. We refer to spasm of the coronary arteries or what is more likely, of the arterioles.¹² Conceivably, this could be induced by irritation of the vessel wall by a deeply penetrating lesion, such as an atheromatous ulcer, or by reflex stimuli from other parts of the body, which secondarily affected the nerve endings in the adventitia. The same mechanism may be responsible for death in those cases in which the heart shows minimal coronary lesions (case 2), for even when numerous atherosclerotic plaques are found at necropsy and at that time appear to cause local constrictions the apparent narrowings in the lumen seen in the dead body may not have existed during life.¹³

As far back as 1923, Gigon¹⁴ reported the death of a diabetic patient with cardiac failure after the third dose of insulin and warned against its use in persons with advanced heart disease. Not long after, Hetenyi¹⁵ noted that insulin hypoglycemia precipitated attacks of anginal pain. Middleton and Oatway,¹⁶ among others, found changes in the form of the electrocardiogram during insulin shock. As a result of clinical observations and a review of the literature, Ernste and Altschule¹⁷ concluded that insulin places an added burden of work on the heart, both by causing hypoglycemia and by sympathetic stimulation. Insulin was being given to two of our diabetic patients, one having received an injection twenty minutes before death and the other eight hours before the unexpected end. To diabetic patients known to have coronary sclerosis, insulin should be given cautiously and in amounts carefully calculated to avoid shock.

With respect to digitalis, the evidence that, in therapeutic doses, it has an action predisposing to sudden death is not convincing. To induce ventricular fibrillation, large amounts, pushed to the point of toxicity, are necessary. In our cases, it was being given to thirteen patients during the period immediately preceding the end. To ten patients none was administered, in one instance no information on this point was obtained. Certainly, in the presence of congestive failure, it should not be withheld. And, on the basis of a considerable experience in giving this drug in maintenance doses to such patients over a period of years, there is reason to believe that so administered, it has prolonged rather than shortened life.

After injection into cats, quinidine raises the threshold for the induction of ventricular fibrillation by faradic stimulation.¹⁸ In such experiments the heart is normal and the method of producing the arrhythmia artificial. In patients, Morawitz and Hochrein¹⁹ believe that they have employed quinidine prophylactically with success in that the number of sudden cardiac deaths in the Leipzig clinic was diminished by giving 0.2 Gm

(3 grains) of this drug daily in all cases of heart disease. They particularly recommend its use in the presence of coronary sclerosis. But until it can be proved that ventricular fibrillation is the usual responsible disturbance and further evidence is adduced that quinidine, taken continuously in the small dosage advocated by these authors, actually lessens the likelihood of sudden death, its routine administration does not seem justified. Larger and presumably more effective doses may cause toxic effects.²⁰ Quinidine can induce as well as prevent or abolish, ventricular fibrillation especially if heart block is present.²¹ It is a drug to be used with caution when there is a possibility that it may do harm.

One other feature relating to this group of cases deserves mention. In patients with coronary sclerosis nonfatal attacks of different sorts and of varying degrees of severity occur. Some of these are unquestionably due to coronary thrombosis or to ischemic necrosis of the heart muscle resulting from an extreme degree of narrowing.²² But there are other cardiac disturbances in which there is no subsequent fever leukocytosis is absent and the blood pressure does not fall. The cardinal symptom may be pain, lasting longer than in the ordinary anginal paroxysm and requiring an opiate for its relief, or pulmonary edema or nocturnal dyspnea of the "asthmatic" type. Often there are showers of premature beats, occasionally transient auricular fibrillation or paroxysmal tachycardia is present. Not infrequently gallop rhythm appears or if previously present, becomes accentuated. The electrocardiogram may alter during the paroxysm, as in an anginal attack,²³ or it may show no changes. If changes are observed they are of short duration, and the record reverts quickly to the form seen prior to the attack. Furthermore, there are no progressive alterations in successive records.

The rate of symptomatic recovery is characteristically rapid. Such relatively mild attacks may conceivably result from the closure of small coronary twigs.²⁴ But it seems probable that frequently they represent minor degrees of acute coronary insufficiency without occlusion and clinically may be regarded as intermediate between the ordinary bout of anginal pain or its equivalent and a fatal seizure. From the point of view of therapy, their recognition is of practical importance. For although after such an episode a period of bed rest is essential the enforcement of a rigid regimen such as is prescribed after an attack of coronary thrombosis is, as a rule, not necessary.

SUMMARY

There is a group of patients with atherosclerosis of the coronary arteries to whom death comes suddenly and in whose coronary vessels, at necropsy, no fresh thrombus is found. The syndrome may be designated "acute, fatal coronary insufficiency."

The clinical and pathologic features of twenty-four cases falling into this category have been studied.

Records of 352 other cases of coronary sclerosis, with and without thrombosis, have been similarly studied and used as a background for comparison.

In approximately 12 per cent of the fatal cases of coronary sclerosis without thrombosis, death occurred suddenly. If thrombosis had occurred, death was sudden in 33 per cent. The presence of thrombosis thus almost tripled the likelihood of sudden death. But thrombosis of a coronary artery was rarely if ever the immediate cause of death in these patients. It increased the liability to acute coronary insufficiency by further reducing the functional capacity of an already impaired coronary system.

Nonfatal attacks of various sorts in patients with coronary sclerosis may be regarded clinically as intermediate between the ordinary bout of anginal pain or its equivalent and a fatal seizure. It is probable that many of these attacks are due to minor degrees of acute coronary insufficiency without occlusion.

DINITROPHENOL POISONING

WITH THROMBOCYTOPENIA, GRANULOPENIA,
ANEMIA AND PURPURA COMPLICATED
BY LUNG ABSCESS

STANLEY W. IMERMAN, MD

AND

CARLYLE P. IMERMAN, MD

HOLLYWOOD, CALIF.

Granulopenia following the oral administration of alpha-dinitrophenol as a therapeutic agent in the treatment of obesity was first reported by Hoffman, Butt and Hickey¹ in April 1934. Since that time five similar cases have appeared in the literature. We are reporting two additional cases because of several unusual features that are presented for the first time following dinitrophenol, namely, anemia, thrombocytopenia, purpura and lung abscess.

CASE 1—History.—A woman, aged 35, complained of sore throat, dysphagia, fever, and general malaise on May 8, 1935. Her condition became worse and on May 14 she admitted having taken dinitrophenol, from 1½ to 3 grains (0.1 to 0.2 Gm) daily, intermittently for the past year to reduce her weight. The only side effect was profuse sweating. For two weeks prior to the onset of the present illness she took 1½ grains (0.1 Gm) daily and lost about 7 pounds (3.2 Kg).

The past history, family history and marital history were not essential. The menses occurred one week late followed by a scanty, intermittent, foul bloody discharge at the onset of the present illness and persisted for about one month.

Examination.—The patient weighed 150 pounds (68 Kg) May 8. The temperature was 101 F; the pulse rate 104; respiratory rate 24 and blood pressure 110 systolic, 90 diastolic. The skin was moist, clammy and pale. The tonsils were acutely inflamed and swollen, with a white grayish membrane. The soft palate, uvula and pharynx were acutely inflamed. There was a scanty foul menstrual discharge. The remainder of the physical examination was negative.

May 14 the temperature was 104; pulse rate 130; the respiratory rate 20; the blood pressure 100 systolic, 70 diastolic. The skin over the chest and axilla showed purpuric spots. The patient was extremely ill. The tonsils were acutely inflamed, with a grayish membrane and ulcerations. The soft palate, uvula and pharynx were acutely inflamed. Blood count showed

hemoglobin 62 per cent, red blood cells 3,320,000, white blood cells 900, polymorphonuclear neutrophils 0 per cent, eosinophils 6 per cent, mature lymphocytes 92.5 per cent, immature lymphocytes 15 per cent, platelets markedly diminished, red blood cells appeared normal on the smear. The urine showed some albumin, a rare cast, a few white blood cells and a few red blood cells. Throat smears showed numerous cocci and a few spirilla. A diagnosis of agranulocytic angina was made and pentnucleotide and liver extract therapy was started.

Progress.—From the 14th to the 19th the patient was semi-conscious and irrational at times. The skin became dry, hard, waxy and warm following each injection of pentnucleotide. The temperature ranged from 103 to 98.2; the pulse 126 to 100; respiration 22 to 20. The purpuric spots on the skin disappeared, but the scanty menstrual flow continued. The ulcers and the membrane on the tonsils, the inflammation of the uvula, and the pharyngitis showed improvement. The temperature, pulse and respiration remained normal from the 19th to the 21st. May 22 the temperature and pulse began to rise, and the patient became very weak and pale and developed a dry cough. On the 27th she was given a transfusion of 350 cc of whole blood and four hours later she developed a pain in the right scapular region and some increase in the cough. Five hours later, shock developed, which lasted for several hours. Portable x-ray films of the chest on the 28th showed an area of consolidation in the upper right lobe consistent with a lobar pneumonia. The patient's condition gradually became worse, fever and tachycardia continued, and two abscesses developed in the buttock and right thigh, which were incised and drained on the 24th. June 18, x-ray films showed an abscess in the upper lobe of the right lung. She was placed on a conservative regimen of bed rest and sedatives, following which the temperature, pulse and respiration became lower and on the 29th the abscess was half its original size. July 20, x-ray films showed a disappearance of the abscess, with a thickened interlobar septum between the upper right and right middle lobes. The patient's general condition is entirely normal at the present time except for an anemia, which has developed within the past month.

Therapy.—Local treatment for the throat consisted of salt and soda throat irrigations, sodium perborate and peroxide gargles. The throat was painted with mercuriochrome and 10 per cent silver nitrate solution. A continuous ice collar was applied. From May 14 to May 24 she received from one to four daily, in all twenty-four, intramuscular injections of 10 cc each of pentnucleotide and from one to two daily, in all thirteen intramuscular injections of 3 cc each of liver extract. May 27 a blood transfusion of 350 cc of whole blood was given, June 4 200 cc of whole blood, and June 11, 200 cc of whole blood. Elver of terpine hydrate with codeine was used for the cough. Other drugs used were magnesium magma, cascara, morphine sulfate, acetylsalicylic acid, papaverine, digitalis, caffeine with sodium benzoate, ephedrine, atropine sulfate, solution of potassium arsenite, reduced iron, pentobarbital sodium, and compound tincture of benzoin steam inhalations. A mustard plaster was used over the right scapula. Local therapy for the abscesses in the right thigh and right buttock consisted of injections of streptococcus serum, and hot magnesium sulfate packs.

Laboratory Work.—Repeated urine examinations showed a moderately heavy trace of albumin, rare casts, a few white blood cells and a few red blood cells. Tests for bile were negative and for urobilinogen positive. Repeated sputum and throat smears and cultures revealed numerous white blood cells, numerous gram-positive cocci in groups and in chains, a moderate number of gram-positive diplococci, a few gram-negative bacilli and diplococci, and a moderate number of gram-positive bacilli, on one occasion a few spirilla, and on June 19 *Streptococcus haemolyticus* and *viridans*. The blood Wassermann reaction was negative. October 3 the sputum smear was negative for tuberculosis and guinea-pig inoculation was negative for tuberculosis. Blood examinations were as follows: May 14, hemoglobin 62 per cent, red blood cells 3,320,000, white blood cells 900, polymorphonuclear neutrophils 0 per cent, eosinophils 6 per cent, lymphocytes 92.5 per cent, immature lymphocytes 15 per cent, platelets decreased. The hemoglobin range was from 50 to 94 per cent, the red blood cell range from 2,570,000 to 5,020,000, the white blood cell

range from 900 to 13,600, the polymorphonuclear neutrophil range from 0 to 705 per cent, basophils 0.5 per cent, the eosinophil range from 1 to 75 per cent, metamyelocytes 1 per cent, the lymphocyte range from 205 to 925 per cent, reticulo-endothelial cells 0.5 per cent, the immature lymphocyte range from 0.5 to 15 per cent, plasma cells 5.5 per cent, immature mononuclears 1 per cent, the mature monocyte range from 3.5 to 23 per cent, the large mononuclear and transitional cell range from 3 to 16.2 per cent, unclassified cells from 0.5 to 2.5 per cent, reticulocytes 0.2 per cent, the platelet range from 30,000 to normal. On blood smear, from May 14 to May 21 the red blood cells appeared normal, from the 22d to the 24th an occasional red blood cell showed polychromatophilia, on the 27th the red blood cells appeared normal. From June 9 to July 13 an occasional red blood cell showed polychromatophilia and slight variation in size. October 15, hemoglobin was 94 per cent, red blood cells 5,020,000, leukocytes 10,200 neutrophils 66 per cent, lymphocytes 20.5 per cent, large mononuclears 12 per cent, eosinophils 1.5 per cent. Blood count Jan 9, 1936 showed hemoglobin 85 per cent, erythrocytes 3,500,000, leukocytes 12,000, lymphocytes 35 per cent, polymorphonuclears 58 per cent, eosinophils 3 per cent, basophils 1 per cent, basket cells 3 per cent, platelet groups normal. A stained smear showed the red blood cells normal in size, regular in shape and taking the stain evenly. No nucleated red blood cells were found. Platelets appeared normal in number.

CASE 2—History—A woman aged 48, became acutely ill July 10, 1935, five weeks after she started taking dinitrophenol for the reduction of her weight. She took 1½ grains (0.1 Gm) of dinitrophenol four times daily for one week and 3 grains (0.2 Gm) twice daily for four weeks, and reduced her weight from 230 pounds (104 Kg) to 215 pounds (97.5 Kg). She noticed extreme warmth and sweating as side effects. July 10, sore throat, dysphagia, extreme malaise, sweating, headache, anorexia, and edema of both legs developed. She had abscesses of the tonsils twenty-two years before. An appendectomy was performed in 1922. A subtotal hysterectomy and left oophorectomy was done in 1927. Cholecystectomy for cholelithiasis was done in 1933. The father died of apoplexy, the mother died of abdominal cancer and one sister died of cancer. Two children were living and well. Menstruation began at the age of 12 years and was regular up to 1927. No menses had occurred since the pelvic operation in 1927.

Examination—July 11 the patient weighed 215 pounds (97.5 Kg), her height was 5 feet 8 inches (173 cm), the temperature was 102.8, the pulse 108, respiration 30 and blood pressure 144 systolic, 52 diastolic. The patient was acutely ill. The skin was moist and clammy. The tonsils soft palate and pharynx were acutely inflamed. There was bilateral pitting edema of both legs. The remainder of the physical examination gave negative results except for abdominal operative scars.

Progress—Blood count July 12 revealed hemoglobin 101 per cent, red blood cells 5,620,000, white blood cells 2,900, polymorphonuclear neutrophils 1 per cent, eosinophils 1 per cent, lymphocytes 82 per cent, transitionals and large mononuclears 16 per cent, platelets normal, the red blood cells showed slight variation in size. Slight polychromasia and basophilic stippling were noted. There was no immaturity of the white blood cells. There appeared to be a toxic depression of the granulocytes. A diagnosis of agranulocytic angina was made and pentnucleotide therapy was started. The temperature, pulse and respirations became normal, July 14, the patient showed rapid improvement, and she had entirely recovered on the 17th.

Therapy—Local therapy to the throat consisted of salt and soda throat irrigations and a continuous ice collar. From July 12 to July 17 she received one or two daily injections, nine in all, of 10 cc each of pentnucleotide. The only other drug used was acetylsalicylic acid the first day of her present illness.

Laboratory Work—Urine examination showed a heavy trace of albumin, numerous white blood cells and a few Trichomonas vaginalis organisms. July 13, throat smears showed gram positive cocci singly and in pairs and chains. Small gram negative bacilli were present. Throat cultures showed Streptococcus viridans and nonhaemolyticus predominating. The blood Wassermann reaction was negative. Blood examinations were as follows: July 12, hemoglobin 101 per cent, red blood cells 5,620,000, white blood cells 2,900, polymorphonuclear neutrophils 1 per cent, eosinophils 1 per cent, lymphocytes 82 per cent, transi-

tionals and large mononuclears 16 per cent, platelets normal, the hemoglobin range from 91 to 118 per cent, the red blood cell range from 5,000,000 to 6,660,000, the white blood cell range from 2,900 to 9,400, the polymorphonuclear neutrophil range from 1 to 60 per cent, the eosinophil range from 0.5 to 4 per cent, myelocytes 5 per cent, the lymphocyte range from 29 to 82 per cent, the transitional and large mononuclear range from 2 to 18 per cent, and platelets from 126,000 to normal. On blood smear, from July 12 to July 15 the red blood cells showed slight variation in size, slight polychromasia and basophilic stippling. There was no immaturity of the white blood cells. There appeared to be a toxic depression of the granulocytes. From the 15th to the 22d the red blood cells appeared normal.

The following is a summary of the eight cases³ of granulopenia following the administration of dinitrophenol.

SUMMARY OF CASES

- 1 All eight patients were women.
- 2 The age limit was from 18 to 48 years.
- 3 Dinitrophenol was used in every case within apparently nontoxic limits.⁴
- 4 Although other drugs were used prior to the onset of the granulopenia, no proved cases of acetphenetidin, quinine, caffeine, acetylsalicylic acid or phenobarbital as an etiologic agent have been reported.⁵
- 5 The most important prodromal symptoms occur from ten days to four months after the drug is started and consist of fever, sore throat and headache.
- 6 The most common signs and symptoms occur from one to eight days after the prodromal symptoms and consist of fever, tachycardia, increased respiration, hyperemia, ulceration, pain and swelling of the gums, pharynx, soft palate, uvula, tonsils, and the mucous membranes of the mouth, cyanosis, stupor, and extreme malaise.
- 7 In the cases in which recovery occurred, the white blood cells and the polymorphonuclear neutrophils responded to therapy in from one to three days, and a normal count was obtained in from six to twenty six days.
- 8 The case of Davidson and Shapiro showed a moderate secondary anemia, which became normal one day after a blood transfusion. The blood platelet count was normal although their patient had a hemorrhagic appearance to the gums. Our case 1 showed a marked secondary anemia, a markedly diminished platelet count, and definite purpuric spots on the skin. Our case 2 showed a definite decrease in the platelet count with out clinical evidence of purpura, and a normal hemoglobin and red blood cell count. The three other cases in which blood counts were taken revealed no anemia and either a normal or an increased platelet count.
- 9 Granulopenia accounts for two of the four fatalities following the use of dinitrophenol⁶ from the recommended apparently nontoxic dose of from 3 to 5 mg per kilogram of body weight.⁴ "It is perhaps malignant neutropenia occurring during dinitrophenol medication that has aroused the greatest professional alarm."⁷
- 10 The five patients who received pentnucleotide recovered. One of the two patients who received

adrenaline sulfate died. The one patient who received only liver extract and blood transfusions died. As our second patient promptly recovered from pentnucleotide alone the value of other forms of therapy such as liver extract, x-rays, leukocytic cream,⁸ leukocytic extract, and blood transfusions are questionable except of course for the treatment of secondary anemia as in our case 1. Local therapy for the throat and general supportive measures are helpful to make the patient comfortable but have no specific curative action.

11 The loss of weight from dinitrophenol was no more than one might expect from dietary measures alone. This corresponds to the opinion of Strang and Evans,⁹ who state that the practical value of dinitrophenol as an aid in weight reduction is very questionable. Dunlop¹⁰ states that it would appear that exceedingly toxic or even lethal doses of dinitrophenol would be required to ensure the same effect as that produced by diets of 1,000 calories.

12 Autopsy¹¹ revealed severe degeneration of the heart, liver and kidneys. This corresponds to the observations of Poole and Haining¹², Tainter and Wood,¹³ De Chatel and Motke¹⁴ and MacBryde and Taussig.¹⁵

COMMENT

Cases of diffuse bone marrow depression following the use of dinitrophenol have not been reported, despite the close relationship of this drug to benzene. Other drugs containing the benzene ring are known both experimentally and clinically to produce anemia, thrombocytopenia, granulopenia and purpura. Selling¹⁶ in 1910 first called attention to the peculiar selective depressant action of benzene on the hematopoietic apparatus. In 1916 he¹⁷ stated that "benzol is a powerful leukotoxin. It destroys the white cells of the circulating blood, and the parenchymal cells of the hematopoietic organs. Myeloid tissue is injured more than lymphoid tissue, and corresponding to this, the polynuclear leukocytes of the circulating blood are more affected than the lymphocytes. The erythroblastic tissue of the bone marrow is destroyed, but the circulating erythrocytes are injured relatively little." Our case 1 illustrates the diffuse nature of the bone marrow depression as evidenced by anemia, thrombocytopenia, leukopenia and granulopenia. Our case 2 reveals the selective damage to the bone marrow as shown by the normal hemoglobin and red blood cell count, thrombocytopenia, leukopenia and granulopenia. The average red blood cell lives in the peripheral circulation from fourteen to thirty days or more, the length of life of the mature neutrophil that reaches the blood stream is from one to six days. It is obvious then that one should take complete blood and platelet counts for at

least two to four weeks on all patients in whom a general bone marrow depression may be suspected and in some cases, as shown by our case 1, blood counts should be taken for several months, as there may be some permanent damage to the erythroblastic tissues of the bone marrow. It might be advisable therefore to institute iron therapy as a prophylactic measure in these cases, before the onset of the anemia. Aisphenamine has produced granulocytic aplasia of the bone marrow as well as numerous cases of aplastic anemia.¹⁸ Farley¹⁹ states that the clinical picture presented by these patients varied according to the degree of bone marrow depression and according to the particular element or elements of the marrow affected. He states that the rarity of occurrences suggests a preceding weakness of the hematopoietic apparatus of the individuals affected. Bionfin and Singerman²⁰ postulate an idiosyncrasy which may be reflected in the entire hematopoietic system as an aplastic anemia or by selectivity, in any of its component parts, producing granulopenia or thrombocytopenic purpura as the case may be. Kracke²¹ has been able to produce the clinical picture of agranulocytosis accurately in the experimental animal by the use of benzene, ortho-oxybenzoic acid and hydroquinone. Madison and Squier²² report a series of fourteen cases of primary granulocytopenia which were directly preceded by the use of aminopyrine alone or in combination with a barbiturate. Experimentally, one rabbit given allylisopropylbarbituric acid and aminopyrine by mouth died on the thirteenth day with a complete absence of granulocytes in the peripheral blood and a marked anemia. They believe that the appearance of primary granulocytopenia following the use of such drugs may be the result of an allergic or anaphylactoid reaction. It is interesting to note that the common factor in all of the drugs mentioned is the benzene ring. The relationship between lung abscess in our case 1 and dinitrophenol cannot be established from one case but should be borne in mind as a possible untoward effect of this drug.

Kracke²³ states that the red blood cells in these cases are little affected except when the illness is prolonged. He also states that there is often a hemorrhagic diathesis due to absent or diminished blood platelets, and it is becoming evident that one cannot draw a hard and fast line between those cases showing neutropenia only and those showing the same condition complicated by diminished platelets, purpura, bleeding and so on. It is further evidenced that in some individuals only the myeloblastic tissues are affected, in some the thrombocytopenic tissues are affected, and in some the erythroblastic tissues are affected or that they may occur in combinations and variations in severity of any or all three.

CONCLUSIONS

1 Dinitrophenol is unpredictably toxic²⁴ except in the one case reported by Fiumess²⁵ and the fact that

THE PREVENTION OF HYPOCHROMIC ANEMIA IN PREGNANCY

JOHN C CORRIGAN, M D

AND

MAURICE B STRAUSS, M D

BOSTON

Within the past decade the high incidence of anemia in pregnancy has become generally appreciated. Although the work of Strauss and Castle,¹ Dieckmann and Wegner² and others has indicated that a 10 to 20 per cent lowering of the hemoglobin during pregnancy may be the result of hydremia and not represent true anemia, approximately 25 per cent of otherwise normal women are definitely anemic following parturition.³ The vast majority of such patients have anemia of the hypochromic variety,⁴ which has come to be associated with a virtual deficiency of available iron for purposes of blood regeneration within the body. Strauss and Castle,⁵ Davies and Shelley⁶ and other clinicians have shown that in pregnancy this anemia is to be associated not only with the presence of the fetus but also with gastric secretory defects and inadequate diets and usually may be completely relieved equally well during as after gestation by the administration of inorganic iron salts in suitable dosage. As a result of modern studies the routine administration of iron to all pregnant women as a prophylactic measure has been advocated.⁷ Our purpose in this communication is to

present an adequately controlled series of observations on 200 pregnant women, 100 of whom received prophylactic iron therapy

Several investigators have undertaken the problem of prophylaxis of anemia in pregnancy. Jerlov⁸ treated 120 moderately anemic pregnant women with iron and noted improvement in 90 per cent. Mackay⁹ observed that thirty women who had been treated with iron both during and after pregnancy had 4.8 per cent higher hemoglobin four months after confinement than a control group of twenty-nine similar women not treated. Davis and Walker¹⁰ administered six different proprietary preparations to a total of eighty-nine pregnant women. No matter what preparation was used, the treated patients showed higher average hemoglobin values than the control patients. The number of patients in each group was so limited, however, that conclusions drawn from the results were not statistically significant. Several of the proprietary remedies employed contained only traces of iron. It is doubtful whether any of the patients received an amount of iron that would be considered adequate in the treatment of hypochromic anemia. Richter and his associates¹¹ administered a proprietary mixture of equine liver extract, glycerated iron and hemoglobin to thirty-eight pregnant women. The average hemoglobin of this group of women was 5.5 per cent higher than that of an untreated group. Irving¹² administered iron, iron and copper and whole liver to pregnant women in successive two month periods during pregnancy. His failure to consider the changes in hemoglobin that occur during such successive periods of pregnancy, as a result of plasma volume changes, unfortunately makes his data of little value.

METHODS

The 200 normal pregnant women studied presented themselves for routine care in the antepartum clinic when they were from three to seven months pregnant, the average being 162 days. On arrival, each patient was assigned a number in order. Blood for examination was withdrawn without stasis from an antecubital vein and a careful dietary history was taken. Every woman was given a bottle containing 100 coated tablets with instructions to take one tablet after each meal and to return the bottle and unused tablets at the next visit to the clinic. At all subsequent visits a fresh bottle of 100 tablets was given the patient. Unknown to her, the number of tablets remaining unused at each visit was counted and from these data the actual amount of medication taken was calculated. Patients who had been assigned odd numbers received tablets containing 0.2 Gm (3 grains) of ferrous sulfate; patients with even numbers received tablets that were identical in appearance and size but contained lactose and no ferrous sulfate.¹³ Women who took less than one of the prescribed three tablets daily were excluded from the two series, as were also those in whom sepsis or hemorrhage developed whether during gestation, parturition or the puerperium. The average daily intake of iron of the treated group was 0.5 Gm (7½ grains) of ferrous sulfate.

At each visit and again one week after parturition, venous blood was withdrawn for examination. Hemo-

13 Smith Kline & French Philadelphia kindly furnished the tablets of ferrous sulfate and the lactose tablets employed in this study

globin determinations were performed at monthly intervals and one week after delivery by the Sahli method, with tubes so calibrated that 100 per cent was considered the equivalent of 15.6 Gm of hemoglobin per hundred cubic centimeters of blood. Red blood cell counts were performed with pipets and counting chambers certified by the U. S. Bureau of Standards.

RESULTS

Initial Examinations—Initial examinations of the two groups of women were made at approximately the same period of pregnancy. The average time after the last menstruation when the treated group first was observed was 160 days, and the untreated group, 164 days.

Forty-six of the women treated with iron partook of diets evaluated as average, which contained meat and vegetables, at least five times a week. Forty-eight women of the control group had similar diets. Seven of the treated women had better than average diets, as did thirteen of the control group. Forty-seven of the treated women and thirty-nine of the untreated women had had definitely poor diets. Thus it is apparent that there were no important differences in the diets of the two groups of women.

The average initial hemoglobin value of the 100 women of the control group was 75 per cent (11.7 Gm per hundred cubic centimeters of blood) and of the

on each of the 200 women are presented in chart 2. At this time the average hemoglobin value of the 100 women who did not receive iron was 75 per cent (11.7 Gm per hundred cubic centimeters), a figure that is in essential agreement with similar data obtained by Kuhn¹⁴, Strauss and Castle,¹ Dickmann and Wegner,² and Bland, Goldstein and First.³ Forty-five of these women had less than this amount of hemoglobin and twenty-four patients had less than 70 per

Chart 1—Hemoglobin percentages in the sixth month of gestation

treated group of 100 women was 73 per cent (11.2 Gm per hundred cubic centimeters) (chart 1). The average initial red blood cell count of the control group was 3.88 million per cubic millimeter and of the treated group 3.72 million per cubic millimeter. There was thus no significant difference in blood levels between the two groups of women when they were first examined at approximately the beginning of the sixth month of pregnancy.

Postpartum Examinations—The results of hemoglobin determinations performed one week post partum

Chart 2—Hemoglobin percentages one week post partum. Solid columns represent patients with less than 70 per cent hemoglobin.

cent (10.9 Gm per hundred cubic centimeters) hemoglobin and hence must be considered to be distinctly anemic.

The average postpartum hemoglobin of the 100 treated women was 85 per cent (13.26 Gm per hundred cubic centimeters), or a gain of 12 per cent over their average values in the sixth month of gestation. Only five of these 100 women had less than 75 per cent hemoglobin and none had less than 70 per cent.

The average erythrocyte count post partum in the control group was 3.94 million per cubic millimeter and in the treated group 4.28 million per cubic millimeter.

COMMENT

In 1930, evidence drawn from a study of three cases was advanced⁵ in favor of the theory that severe hypochromic anemia in pregnancy was due to a virtual deficiency of iron brought about by gastric secretory defects in the presence of fetal blood requirements. Subsequent studies¹⁵ verified this theory and led to the suggestion that iron be employed as a prophylactic of hypochromic anemia in pregnancy. The data presented here unequivocally demonstrate that, in the absence of hemorrhage or sepsis, the daily administration of 0.5 Gm of ferrous sulfate to women in the last trimester of pregnancy results in higher hemoglobin values than in untreated women.

SUMMARY

Two hundred women were studied during the last four months of pregnancy. Alternate patients were given 0.5 Gm of ferrous sulfate daily. The others

15. Strauss and Castle,¹ Davies and Shelley.⁴

received placebos. Of the 100 women given no iron, twenty-four had less than 70 per cent hemoglobin post partum. Of the 100 women given iron, none had less than 70 per cent hemoglobin post partum.

The conclusion is drawn that hypochromic anemia in pregnancy may be largely prevented by the routine administration of iron, especially in the latter months of gestation.

RAT-BITE FEVER FROM FIELD MOUSE

R. J. REITZEL, M.D. ARTHUR HAIM, M.D. AND
KIRK PRINDLE, M.D. SAN FRANCISCO

Rat-bite fever, or sodoku, is now a widely known disease. In most cases the disease is caused by the bite of rats and only rarely by the bite of other animals, such as dogs, cats or ferrets. In 1932 in Germany Jungbluth¹ reported that a boy, aged 9 years, who had been bitten by a field mouse developed a disease which clinically resembled rat-bite fever. The demonstration of spirilla was not possible. Bruning² included this case in a compilation of sixty-five cases of sodoku in children as the only one in which the patient was not bitten by a rat. In 1932 also, Jenkinson and Jordan³ published a report from North America of the development of rat-bite fever in a man, aged 56, who was bitten by a wild mouse; the diagnosis could be made only by clinical evidence, all efforts to demonstrate the causative organism failed.

We believe that the following case, which we studied in 1934, is the first in which the bite of a field mouse produced a typical rat-bite fever in which spirilla were demonstrated as the cause.

REPORT OF CASE

History—May 30, 1934, a previously healthy schoolboy (T. E.), aged 14, was bitten on the left fourth finger by a wild field mouse that he had captured in a California hay meadow. The wound was small, bled freely, and in a few days healed without soreness or signs of inflammation. June 11, however, there was pain and slight swelling at the site of the bite, and there was a general feeling of malaise, headache, and a loss of appetite. June 14 the finger was incised, but no pus was obtained. The patient was admitted to Mills Memorial Hospital, San Mateo, Calif., June 17.

At the time of admission, he had a temperature of 103 F, pulse 110, respirations 20. His cheeks were flushed and he exhibited sporadic muscular twitching in the muscles of his face, abdomen and extremities. There were no abnormal manifestations aside from a soft blowing localized systolic murmur over the apex of the heart, and a grayish dry crust about 0.5 cm in diameter, at the base of the left fourth finger surrounded by considerable cellulitis. There was no fluctuation and the tenderness was slight. There were no signs of lymphangitis. The left epitrochlear glands were painful and were moderately enlarged. Removal of the crust left an ulcer 0.5 cm deep, which did not bleed.

Clinical Course—The temperature is given in the accompanying chart. Throughout the entire illness there were no subjective symptoms except headache, malaise and chills as one would expect, with rise in temperature. June 20 the spleen was palpable for the first time 1 cm below the costal margin. June 23 a small urticaria-like wheal was visible on the inner surface of the right thigh. The next day numerous slightly raised reddened areas, varying in diameter from 0.5 to 1 cm, appeared on the dorsal surface of the left forearm. During

the next two days, similar widely scattered lesions appeared on the hips, cheeks, chest, thighs and lower portion of the legs. At the height of their development (which was during the third to the fourth day after the initial appearance of the rash) the skin lesions appeared as discrete, purplish red, indurated nodules, not painful, tender or itching.

Medication—June 24, 0.15 Gm of neoarsphenamine was given intravenously. June 26, 0.3 Gm was given. June 28, 0.15 Gm was given. Following the second dose, the rash disappeared rapidly and the temperature fell to normal. The patient left the hospital in June and appeared entirely well until July 16, when his temperature suddenly rose to 103 F. No skin lesions were manifest but there was slight generalized adenopathy. He was given 0.15 Gm of neoarsphenamine. The next day his temperature rose to 105 F, and 0.3 Gm of neoarsphenamine was given. The following morning his temperature fell to normal and remained so. July 19 he was again given 0.3 Gm of neoarsphenamine and July 24 a final dose of 0.4 Gm, at which time he was apparently well and the adenopathy had almost entirely disappeared. He had no further relapses.

Laboratory and Bacteriologic Data—On the sixth day after entry to the hospital, the urine showed a trace of albumin and a few hyaline casts.

There was no anemia. The leukocyte count on entry was 4,400 polymorphonuclears, 67 per cent, lymphocytes, 22 per cent, monocytes, 9 per cent, basophils, 1 per cent. Daily leukocyte counts were made and the total number of cells remained

Temperature curve

low with practically the same differential count until June 26, when the white cell count rose to 7,900 with a normal differential count. The blood Wassermann reaction was negative on two occasions.

Cultures taken from the site of the wound and from the blood were repeatedly negative for pathogenic organisms. Agglutination tests for tularemia and brucellosis were negative.

Tissue fluid from the wound, which was inoculated into mice, was negative. Repeated examinations of smears of the patient's blood examined after using Wright's and Giemsa's stains were negative. Twice, citrated venous blood was inoculated into white mice and guinea-pigs intraperitoneally and into a rabbit intravenously. June 23 a lymph node was removed from the left epitrochlear region. This was ground up and inoculated into white mice and guinea-pigs. Positive results were obtained only in the mice. In one mouse (gland) the organisms were found after fourteen days and in another (blood) after sixteen days, following daily darkfield examinations of the blood taken from the tail.

The parasites showed all characteristic features of *Spirillum minus* (Carter), which is identical with *Spirochaeta morsus muris* described by the Japanese authors and generally accepted as the causative organism of rat-bite fever (sodoku). The darkfield illumination revealed the spirilla as having rigid bodies with rapidly moving bipolar flagella. The stained smears showed them to be from 2 to 5 microns in length with three to four waves.

The authors acknowledge a assistance from the George Williams Hooper Foundation for Medical Research, University of California.

2. Bruning H. Sodoku (Rattenhisskrankheit) bei Kindern. *Ergebn d inn Med u Kinderh* 44: 1 1932.

3. Jenkinson H R and Jordan C F. A Case of Rat Bite Fever Caused by the Bite of a Wild Mouse. *J Iowa M Soc* 22: 31 (Jan) 1932.

Blood of the positive mice was repeatedly transferred to white mice. The strain is still kept going (after one year). The incubation time has become shorter with successive passages and is now around five days, depending mostly on the number of injected organisms and the individual susceptibility of the animals.

It may be mentioned that not in one instance was *Spirillum minus* found in these mice before the experimental infection.

SUMMARY AND CONCLUSIONS

A boy, aged 14, was bitten by a wild field mouse and developed rat bite fever. Venous blood and emulsified lymph node obtained at biopsy and injected into white mice revealed *Spirillum minus*. Cure was effected by the administration of nearsphenamine.

Apparently healthy rats and mice may harbor spirilla, which are similar to and even identical with those demonstrated in rat bite fever in man. Any bite by animals, particularly rodents, should be considered as a possible source for this disease. Prophylactic administration of nearsphenamine may even be considered, and, in case of clinical evidence of the disease, nearsphenamine should be administered immediately, as animal inoculations in our case were not found to be positive before the fourteenth or sixteenth day.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS
HOWARD A. CARTER, Secretary

INDUCTOTHERM (ONE TUBE) ACCEPTABLE

Manufacturer: General Electric X-Ray Corporation, Chicago

In THE JOURNAL, May 11, 1935, page 1706 the acceptance of the General Electric Inductotherm (two tube) was published. Since then the General Electric X-Ray Corporation has designed a new unit, which is somewhat smaller but, according to the company's engineers, has the same power output. Instead of two tubes being used in this new machine only one tube is employed, but it is much larger and more efficient, thus giving approximately the same power with the one tube that was formerly developed by two smaller tubes. In order to obtain this power, however, it is necessary to be more careful about the placement of the coil applicator.

The physical and electrical tests showed that the electrical equipment was reliable and met the requirements of the Council. The shipping weight is approximately 200 pounds. A schematic diagram of the circuit is shown.

Tests similar to those performed by Mortimer and Osborne and reported in THE JOURNAL, April 20, 1935, were conducted in a clinic acceptable to the Council to determine the efficacy of the one tube model of the General Electric Inductotherm for producing heat in living tissues.

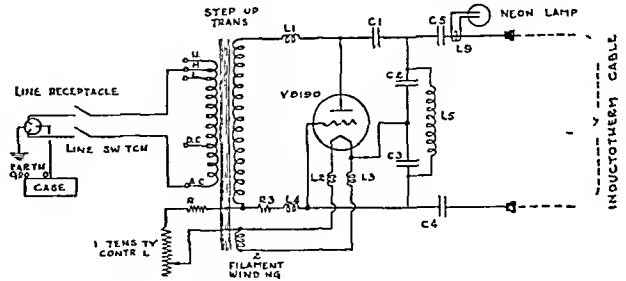

In all, eight tests were made on eight different subjects. Three turns of cable were wrapped around the human thigh, the coils being separated from the skin by three-fourths inch padding. The application time was twenty minutes.

The results obtained indicated that the final temperature in the muscle (quadriceps extensor) was 105.4 F, while the temperature rise was 68 degrees F, in the subcutaneous tissues the final temperature was 104.8 F and rise 7.6 degrees F, and on the skin surface under the padding the final temperature was 101.0 F and the rise 5.2 degrees F. The month temperature rise was 0.6 degree F. Each item aforementioned is the average of eight observations. The intensity of the current was governed by the patient's tolerance.

In a series of five fever treatments on different patients the average time the Inductotherm was on was about two hours and the average final rectal temperature was about 105 F. The average initial temperature was 99.04 F. The average rise was therefore 6 degrees, or 3 degrees per hour.

The technique employed was as follows. A treatment bag was opened and a full length rubber sheet to protect the bag from

perspiration was inserted. The rubber sheet was then covered with a terry-cloth blanket, folded once longitudinally. The open side was then placed toward the side of the bag having the opening for taking rectal temperatures. The patient was placed within the blanket with a terry-cloth blanket pinned as a shawl around his neck. A full size blanket was then placed over the terry-cloth covering the patient and the treatment bag closed. The 12 inch disk electrode was positioned approximately half over the chest and half over the abdomen of the patient. A full

MEDICAL PROBLEMS CREATED BY THE FLOODS

The magnitude of the task for sanitary engineers and physicians created by the extensive floods in the East is only beginning to be realized. The flood menace is nothing new in the history of mankind, it has been one of the most terrifying of the natural phenomena recorded in legend and history. The health problems created by floods are naturally somewhat modified by their location, extent and season.

While it is impossible to distinguish sharply between the strictly sanitary problems and the direct danger of infectious disease, some division may be recognized. The sanitary problems are manifold. Perhaps most pressing is the water supply. Extensive contamination must have occurred in the large centers as well as in the rural districts. The floods of the past have done much to show the importance of immediate attention to this problem. Emergency measures, such as chlorination, filtration and boiling, must be established immediately. In some communities, force may be required to prevent the widespread ingestion of contaminated water by many people. An integral part of this program is the adequate disposal of sewage. The extensive utilization of chlorinated lime is advised as most immediately effective.

Food supply is only less important than water supply. The rapidity with which a crisis can be reached is evidenced by the riots for food which, newspapers report, occurred in the Pittsburgh district.

In some regions insect control, especially of malaria-bearing mosquitoes, is of enormous importance. In the Mississippi valley floods in the spring of 1927, screening for malaria was demanded. In some of the districts involved in the present floods this may again be important. The season of the year, however, makes the danger of these insects as well as of flies less significant than might be the case later on.

The sanitary factors are primarily concerned with the prevention of intestinal diseases. Typhoid fever, bacterial and amebic dysentery and paratyphoid infections are most likely. Much can be learned from past

floods as to the sanitary measures that can be employed to this end. The most extensive recent flood in this country was that of 1927, which involved Arkansas, Kentucky, Louisiana, Mississippi, Missouri and Tennessee. At that time measures were so efficient that there was in many states a lessened incidence of infectious disease as compared with that of previous years free from floods.

Hand in hand with the necessary sanitary measures must go the specific measures for disease prevention. Most important is typhoid immunization. In the 1927 flood approximately 500,000 complete typhoid immunizations were administered, and the demand for typhoid vaccine today will probably exceed considerably the demand at that time. Doubtless these immunizations have been begun on a large scale already. Smallpox vaccination is equally imperative. About 150,000 vaccinations for smallpox were given at the time of the Mississippi floods, and though it is probable that a somewhat smaller proportion of unvaccinated individuals reside in the present flooded areas, the demand for vaccine will undoubtedly be great.

The large number of individuals who have had to move out of their homes has necessitated in many instances crowding into small quarters similar to that which existed in the concentration camps at the time of the World War. Such crowding inevitably favors the propagation of epidemic disease. It is difficult to know what epidemic diseases might be most likely to become rampant. Certainly influenza and epidemic meningitis must be anticipated with the greatest possible vigilance.

Great disasters involving a large number of refugees require also special measures to prevent the spread of venereal diseases. The Mississippi floods of 1927 involved mostly rural communities, with large urban groups crowded together in the present floods, the prevention of the venereal diseases may be even more difficult.

Judging from past experience, it is probable that the diseases produced by direct exposure will be less than might be anticipated. For the most part they will involve only persons directly exposed to the elements for long periods of time, such as policemen, national guardsmen and those engaged directly in rescue work. The season of the year, however, enhances the possibility of the spread of the diseases caused largely by direct exposure. Of these the most important is unquestionably pneumonia. No doubt there will be a considerable increase in the number of cases of this disease over that ordinarily expected at this season of the year. Because of the recognition of this danger, however, many individuals will take somewhat better care to guard against it than they would under ordinary circumstances.

The menaces briefly mentioned here are some of the most obvious and easily predictable. In themselves they offer problems of gigantic proportions to public

agencies and to physicians. Unfortunately there are likely to be other and unexpected health complications. What these may be will probably not become known for some weeks after the emergency has largely passed. Some slight permanent benefit may be obtained from the fact that large groups of people are immunized to certain diseases and from the fact that some, for the first time, will learn the importance of sanitation and disease prevention.

REESTABLISHMENT OF MEDICAL R O T C UNITS

The medical reserve officers training corps units that were established between 1920 and 1922 in some of the leading medical colleges of the country graduated more than 6,000 students. The courses were conducted by officers of the medical Corps of the Regular Army. More than half of the Medical Reserve officers commissioned during the last ten years are R O T C graduates. Moreover the system has served to establish valuable contact between the Medical Department of the Army and centers of medical education. In times of national military emergency, expansion must obviously begin in these centers of medical education.

During the past four years the congressional appropriation acts for the support of the army have contained a provision that funds appropriated for the army R O T C units would not be available for medical R O T C units. As a result these units, which were established in twenty-four of the medical schools of the country, were curtailed year by year until the effect of the legislation in 1935 was to abolish them completely. This year, however, the Senate Committee on Appropriations has included provision for medical R O T C units. This would authorize the War Department to reestablish such units during the current year and would permit the department to set them up in each of the medical schools in which such units were previously conducted. The bill as passed by the Senate now goes to the House of Representatives.

The House of Delegates of the American Medical Association, at its annual session in 1935, adopted a resolution urging the reestablishment and maintenance of facilities for the preliminary military training of medical officers. Even the most ardent pacifist must recognize the necessity for an efficient medical corps in the army of any nation. The medical corps keeps out of military service those who are physically and mentally unfit. It conserves the health of those who enter the service. The physician who limits his activities to private practice cannot, however, be familiar with many procedures that are implicit in the work of the army medical officer. Army medical service demands knowledge of camp sanitation and hygiene, the keeping of efficient records, organization of hospital and special military units, and military precedents, rank and etiquette, which can be acquired only by suitable training. Obviously it is not practical to delay the training of

physicians in these matters until after hostilities have begun. Provision for such training in medical schools during times of peace will mean that the Medical Corps of the Army will have at all times available a considerable body of suitably trained men who may be called when occasion demands.

The act of Congress correcting the discrimination against medical reserve officers training corps units has already passed the Senate and, as previously stated, now goes to the House of Representatives, where it is known as H. R. 11035. In the ordinary course of business the Senate and the House will appoint conferees to adjust the differences in the bill as passed by the two bodies. The fate of the Senate amendment authorizing the establishment of medical units depends primarily, therefore, on the action of the conference committee. Favorable action will be hailed by the medical profession as a recognition of the importance of medicine in the scheme of national defense.

THE RÔLE OF ESTROGENIC SUBSTANCE IN TUMOR FORMATION

Evidence that the ovary may be implicated in the production of cancer of the breast has long been available. Twenty years ago Lathrop and Leo Loeb¹ demonstrated that ovariectomy in mice during the first few months of life definitely reduces the incidence of mammary cancer. Subsequent extirpation and transplantation experiments by Cori and by Murray extended these observations. When pure estrogenic compounds became available, attempts naturally were made to test the effects of injection of these substances on the production of mammary cancer. Thus, Lacassagne demonstrated that long continued administration of estrogenic substance to mice, of a strain in which only the females normally develop spontaneous mammary adenocarcinomas, leads to the development of such malignant tumors in the males. On the basis of these and other experiments the Council on Pharmacy and Chemistry² warned three years ago that "the possibility [of deleterious effect from the clinical administration of estrogenic substance] deserves serious consideration, particularly if the large doses more recently employed clinically should come into common usage." That the Council's admonition was warranted has become increasingly apparent as further experiments have confirmed and extended the earlier studies. Burrows³ and Bonser⁴ have confirmed Lacassagne's observations, and suggestive results have been reported by Loeb¹.

1 The literature is critically reviewed by Loeb Leo. *Estrogenic Hormones and Carcinogenesis* chapter XIII of *Glandular Physiology and Therapy*. Chicago: American Medical Association, 1935.

2 *Estrogenic Substances*. Theelin report of the Council on Pharmacy and Chemistry. *J. A. M. A.* 100: 1331 (April 29) 1933.

3 Burrows Harold. Carcinoma Mammæ Occurring in a Male Younger Under Continued Treatment with Oestrin. *Am. J. Cancer* 21: 613 (July) 1935.

4 Bonser G. M. Carcinoma of the Male Breast in Mice Induced with Oestrin. *J. Path. & Bact.* 41: 217 (July) 1935.

More recently another investigation of this question has been published, Gardner and his co-workers⁵ injected large doses of estrogenic substance in oil into male mice of a high tumor rate strain. Mammary cancers developed in eight of the animals following treatment (this almost never occurs spontaneously in the males). One of the tumors grew rapidly on transplantation into other mice.

Much evidence is now available that estrogenic substances may predispose to the development of pathologic proliferation in tissues that normally respond to their presence by growth. In addition to breast tissue in both sexes, this has been noted in the uterine cervix and endometrium⁶ of the female and in the prostate and other genital organs of the male,⁷ in animal experiments. Evidence has also been adduced that estrogenic hormone is concerned in the production of uterine and breast tumors and even of prostatic hypertrophy in human beings.⁸ High titers of estrogenic principle have been noted in tumors of the breast and uterus.⁹

While further well controlled studies will be necessary to establish definitely the role of estrogenic substances in various pathologic proliferative processes (particularly the effects of the different compounds), present knowledge indicates the necessity for caution in the prolonged use of large doses, especially in patients in whom there is reason to suspect susceptibility to cancer.

Current Comment

EFFECT OF LIVER EXTRACTS IN EXPERIMENTAL AMEBIASIS

The elucidation of the role of dietary factors in the control of intestinal amebiasis is an important problem. The investigations of Faust and his collaborators have demonstrated the ameliorative effects of feeding raw liver or powdered liver extract to dogs infected by intracecal inoculation of *Endamoeba histolytica*, in some cases complete eradication of the protozoon occurred with this treatment alone.¹ However, the nature, identity and mechanism of action of the sub-

stance in liver responsible for these effects is not known. The active material is destroyed by heating in an autoclave at 17 pounds pressure for twenty minutes, it is apparently present largely if not chiefly in the liquid fraction of raw liver. Desiccated stomach has no ameliorative effect (but actually a deleterious effect) unless it has first been heated in an autoclave. The identity of the active substance with the antianemic principle has been questionable. Recently, Faust and Swartzwelder² have investigated the effect of purified liver extracts administered intramuscularly on experimental amebiasis in dogs. Fourteen infected animals were injected every two or three days with 2 or 3 cc of extract (each cubic centimeter representing 5 Gm of pig's liver), six dogs received a commercial extract and eight a special extract prepared by the investigators. Contrary to the effects of feeding liver or liver fractions, the extract administered intramuscularly failed to control the infection although the erythrocyte count was increased. Faust and Swartzwelder conclude that "the fraction of raw liver which is efficacious as an amebostatic agent is either different from that which [produces] erythropoiesis or its amebostatic action is inhibited when it is introduced intramuscularly."

SHORT WAVE DIATHERMY— "THE SHADOW"

In radio channels between 37 and 11 meters there has appeared of late a mysterious radio interference, said by radio engineers to be due to everything from "celestial invasions" to the malice of an "antisocial crank." Reports indicate that the interference has conflicted with commercial and amateur broadcasting, with some government stations and even with radio communications during the recent stratosphere flights. Now Prof. Harry Rowe Mimmo of Cruft Laboratory, Harvard University, seems to have traced the interference, in at least one instance, to a short wave diathermy machine used on the Harvard University campus. Professor Mimmo reports that code signals broadcast by the machine were picked up at the Naval Research Laboratory at Bellevue, D. C. Moreover, an editorial in the February issue of *Q. S. T.*, the official organ of the American Radio Relay League (organization of radio amateurs known as "hams"), states that communication signals emanating in Boston were picked up by receiving stations at Norfolk, Washington, Bellevue and the Great Lakes. The short wave machine was not equipped with an antenna and the radio frequency energy was fed back into the power wires, hence the alternating current power supply system was the antenna. Each manufacturer of short wave diathermy equipment has his favorite wavelength or wavelengths and asserts that these are most efficient for therapeutic purposes. The Council on Physical Therapy of the American Medical Association does not accept the claim that one wavelength is more efficient than another. Since certain radio channels have been allocated to commercial, navy and army stations and also to amateur radio enthusiasts, manufacturers of short wave diathermy equipment could solve the question of interfer-

ence by developing evidence to substantiate the efficiency of some one wavelength, which channel could then be assigned to them for therapeutic purposes. In the meantime those accused of interfering with radio communication may consult manufacturers as to proper methods of screening and minimizing interference.

Medical Economics

MEDICAL SOCIETY AGREEMENT FOR CARE OF THE INDIGENT SICK

Mahoning County Medical Society (Ohio) has recently entered into a contract with the county commissioners, for the giving of medical relief, that has some novel features. Entire control of the responsibility for medical care is vested with the county medical society. Fee schedules formerly set up under the FERA are accepted. The individual physician has no direct relations with the county relief agencies. All such arrangements are handled by the county medical society as a unit. The county medical society is made responsible for the character of the medical care and the discipline of its members. The agreement in full is given below.

AGREEMENT

This agreement between the County Commissioners of Mahoning County and the Mahoning County Medical Society

WITNESSETH

WHEREAS There is a temporary shortage of money for medical relief and

WHEREAS The physicians of Mahoning County are willing to arrange some practical and permanent plan of medical care for those on relief and

WHEREAS It is the agreement of the Mahoning County Medical Society and the Commissioners of Mahoning County that the fees for merely paid by Federal Relief to the physicians of Mahoning County are satisfactory for the present to both parties

NOW THEREFORE

It is agreed between the parties hereto

(1) That such fees shall be in effect until July 15 1936 at which time there shall be negotiations for a new fee schedule

(2) That the County Commissioners will not set up clinics for the treatment of any special type of disease

(3) That all matters relative to the conduct of practicing physicians in Mahoning County in their relations with the County Commissioners shall be subject to and passed upon by the Medical Economics Committee of the Mahoning County Medical Society

(4) That a board composed of the Economics Committee of the Mahoning County Medical Society one dentist one nurse one pharmacist and one representative of the hospitals be empowered by the Mahoning County Commissioners to suspend either temporarily or permanently any physician after a fair and impartial hearing whose conduct is unbecoming that of a physician and a gentleman and that this action will be final. That any practitioner of medicine found guilty of unprofessional conduct in his treatment of the indigent sick of Mahoning County shall have his name removed from the eligible list and shall not receive remuneration from Mahoning County for the care of the indigent sick of this county

(5) That the medical relief office be under the direct supervision of physicians who shall spend the necessary amount of time in that office to insure its proper and efficient operation. These physicians to be under the direction and supervision of the Economics Committee of the Mahoning County Medical Society

(6) That the manner of rendering bills be set up with no more red tape than is necessary. That an itemized statement and diagnosis be required. That red tape and clerical work be abolished. That bills so rendered be paid within thirty days after receipt of statement

(7) That the duties of the medical relief office be clearly and distinctly divorced from the office of the County Health Officer and the city health commissioners and that the County Commissioners deal only with the duly appointed committees of the Mahoning County Medical Society in regard to medical relief matters

(8) That under no circumstances are verbal conversations to be taken as authentic but that all orders intents etc be clearly expressed in writing and signed by the proper authority

(9) This agreement may be rescinded by either party on ten (10) days notice by either party to the other

IN WITNESS THEREOF the parties hereto have hereunto set their hands to duplicate copies hereof this

day of February 1936

MAHONING COUNTY MEDICAL SOCIETY

BY

MAHONING COUNTY COMMISSIONERS

WITNESSES

COMMENT

This agreement is distinguished by its simplicity and clarity. It is clearly based on the existence of a cooperative spirit between the county medical society and the county commissioners. The temporary and emergency character of the fee schedule is definitely recognized. The establishment of undesirable patterns of medical service, such as free clinics, is prohibited. While the county medical society is given direct supervision of medical service, there is a provision for arbitration of differences and discipline for conduct at variance with medical ethics or with the provisions of the agreement. Unnecessary red tape is definitely eliminated. A clear line of separation is drawn between the practice of medicine and the administration of public health. The emergency character is insured by a provision for termination with ten days' notice.

ANNUAL CONGRESS ON MEDICAL EDUCATION, MEDICAL LICENSURE AND HOSPITALS

Thirty Second Annual Meeting held in Chicago Feb 17 and 18 1936

DR FREDERIC A WASHBURN, Boston,
in the Chair

COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

FEBRUARY 17—MORNING

Report of the Council on Medical Education and Hospitals

DR RAY LYMAN WILBUR, Stanford University, Calif. Today medical education is one of the severest of all the mental disciplines. It requires a decade or more of thorough training of the mind and of the body. It demands both expert technical training and sound mental processes. The training of the hands and of the brain must go together. On looking over the last twenty-five years of medical education in the United States one finds that there has been an expansion of equipment personnel and curriculum to meet the expanding knowledge and the increased requirements of medical practice. A decade and a half ago in the attempt to cover everything there was an engorged and almost impossible curriculum. At the present time the stage of shaking the curriculum down to its fundamental core is being gone through. The survey of the medical schools that has been going on during the past year has brought out clearly the considerable variations in different parts of the country and the strange combinations of tradition, strong personalities, and the absence of necessary funds to do up-to-date educational work in most parts of some medical schools and in some parts of all, or nearly all, medical schools.

Sometimes extensive education and prolonged training are belittled by those who think there are short cuts to health and trick ways to recognize diseases and treat the sick. The calls on the young doctor are so various and so imperative that in our zeal we may have tried to be too inclusive in the multiplicity of subjects offered him. It is now essential that in every department in the medical school and in every part of the curriculum we should weigh, ponder, evaluate, choose and discard so that we shall not provide more than can be absorbed. The antique, the petty, the nonessential should be tossed aside by both the schools and the examining boards. Above all, the principles of biology, chemistry and physics must be the ever present substratum to the knowledge of body structure, physiology and pathology.

Since we can in no way fully prepare the physician for what he will actually do ten years ahead, we must provide him an understanding of fundamentals so that he can pick and choose. We cannot foresee what ten more years of medical research will bring. Compare the treatment of diabetes today with a few years ago and this point is clear. Nevertheless the young doctor must know the immediate actualities of every day in

the care of the sick and be abreast of the best of the days of his training. The required intern year is little enough to ask in the way of additional preparation beyond the classroom and the clinic. In some schools there still lurks the superstition that doctors can be made by textbooks, lectures and charts but only through the living, suffering human being can the care of the sick and the protection of the well be learned. This is the reason for our clinics, hospitals and nurses—forming the heart of our medical schools. The laboratory is simply more bedside equipment, not an end in itself.

Some academic teachers in all parts of the medical school are now a requisite for first-class work. I use the term "academic" rather than "full time" as I resent any such imputation in the university or medical school. A professor should meet his major obligations to his institution but should have a considerable part of his time under his own control to use for such research study or other enterprise as he may determine with his own knowledge of himself and what he can do and likes to do. In brief, all departments need some men on salaries to ensure good and steady work. To turn a class of medical students into capable physicians requires the energies and time of a comparatively large faculty on which there is some room for all kinds of talents and a variety of practitioners.

Medical centers are inevitable in all communities and the center formed by a medical school and its hospitals has the most promise of success. More and more the physician is becoming the agent of society. Medical economics is now generally recognized as a need of medical students, but little has been done about it. We are baffled as to how to proceed. We want the young doctor to know something about it, but not enough to break away from what are supposed to be our special traditions. Everything is becoming more costly as medicine becomes more scientific. The most striking finding of our survey of the medical schools is the lack of adequate funds, and the most glaring weaknesses of the schools could be largely cured with dollars. A continuation of large gifts and large appropriations for all our schools is requisite if there are to be adequate research, good training of the young physician, and excellent care of the sick. Next in significance to the training of medical students is the continuous and effective education of the doctor. Our largest cities are not yet great medical centers for postgraduate training, but a number of consequential steps have been taken.

So far as we have gone with this present survey, we have been impressed by the great improvements made and the fine spirit of the medical faculties, and with the large amount of sound research under way.

The Accrediting of Higher Institutions

GEORGE F. ZOOK, PH.D., Washington, D.C. To any one who has studied the history of the professions it seems clear that they themselves should exercise extended control over the nature of the preparation which individuals should offer for entrance into them and even the number who are admitted to their privileges. Who, if not the members of the profession, can be counted on to know its problems and to be a competent judge of the quality of its personnel? In the last twenty-five years medicine offers us the clearest demonstration of the fact that in America the members of a profession who are both wise and zealous will be accorded the most extended control over the development of their profession. Yet I believe that we are at the beginning of a new era which demands as much vision and courage to solve the problems of accrediting as our predecessors exhibited a generation ago.

In the first place the increasing success which attends the accrediting of individuals who enter medical schools as students tends to reduce the importance of accrediting educational institutions. Every time that, through the giving of a general intelligence test, a medical aptitude test or any other measure of probable success in medical schools, we increase our ability to identify successful medical students, to that extent we make less necessary reference to the long list of accredited high schools and colleges in which they happen to secure their pre-medical education.

Secondly, I believe that the accrediting of medical colleges should be turned over largely to the medical colleges them-

selves. I believe that the present system of accrediting opens the profession to serious attack, perhaps unjustifiably, both from within and from without the medical profession. So long as so much illness and so many surgical needs go unattended there are those who will never be satisfied that the number of students in medical colleges should be reduced by the action of the medical profession, as is being accomplished in part through the visitation now under way. The opposition to the attempt to discontinue the accrediting of the two-year medical schools can be interpreted in no other way, I suppose, than as a warning from medical educators that the accrediting of medical schools is really their affair. It would seem indeed that the action of the Council on Medical Education and Hospitals in June 1933, accepting the statement of the Association of American Medical Colleges relative to admission requirements and the medical curriculum as an integral part of the requirements or "Essentials of an Acceptable Medical School," was a recognition of the jurisdiction of the colleges themselves in a matter of this kind. I am convinced also that the medical colleges for their own good, need to have the responsibility for their own accrediting. The period for policing medical schools is about over, or, to be more accurate, it will in the development of medical education be of less and less importance. The reduction in medical schools has been carried to the point at which hereafter there will be more and more division of opinion on all matters involving drastic action. The medical schools that have survived the early period of rigor have for the most part grown up into responsible organizations. Hereafter the real problem will be to set at work the forces for self improvement throughout the medical colleges of the country, to encourage those who are low in attainment to emulate the more successful institutions, and to stimulate even the best institutions to new and greater levels of achievement.

The stimulation of higher institutions to self improvement and superior standards can best be done through precept and example by those who are themselves engaged in the work. The first requirement is that institutions be able to cast aside, temporarily at least, outside restraints which inhibit experimentation with unconventional processes.

There is another process on which all accrediting agencies have placed great reliance, namely, that of inspection. An outside inspector, or inspectors who are known to be thoroughly competent and sympathetic can do more to jar an institution loose from a spirit of dull complacency than almost anything one can think of. I am convinced, therefore, that for purposes both of accrediting and of stimulation the device of visitation is highly desirable. The Council on Medical Education and Hospitals has wisely chosen as inspectors people out of the medical schools themselves who are known to be thoroughly competent. Nevertheless, the inspectors have represented essentially an outside organization. They have been received with a certain amount of trepidation almost everywhere. I venture the opinion that even in the better institutions the inspections have been too much in the nature of detailed criticisms. There is not enough of the element of friendly stimulation, which should be the keynote for the visitation at all institutions save those which may properly be regarded as marginal in character.

My last observation is that accrediting agencies in higher education should eliminate quantitative standards and go over completely to a frank attempt to evaluate qualitatively the processes and product of higher institutions. In the earlier days it was natural that good institutions should be defined in terms of physical plant, endowment, semester hours and faculty preparation. These criteria were quantitative and they were merely somebody's opinion. Furthermore, while they were crude measures they served their day well. But today when we are able to apply far more reliable measures of individual diagnosis and growth and when judgment as to both individual and institutional status may be rendered much more reliably than in those earlier days. We should cast off quantitative standards in favor of qualitative criteria in evaluating the work of higher institutions.

In recent years, the movement in medical education has been in the direction of qualitative criteria and away from quantitative considerations. Even the regulation concerning the specific number of semester hours in chemistry, physics, biology,

and English have been removed and the Association of American Medical Colleges has gone on record as being opposed to premedical curriculums, preferring that students who enter medical schools should during their college years be not in any way set apart from other students

It is the duty of those interested in education to see that the evaluation of the schools and colleges is undertaken by those who are most competent and that they use criteria and methods which are valid and stimulating. Of equal importance is the fundamental conclusion that the present minimum specific standards for higher institutions should be replaced by optimum general criteria. The implications resulting from this radical change in policy will make it necessary to revamp the whole procedure of accrediting. It opens the way for an accrediting organization to expend the major part of its energy in a program of friendly stimulation and assistance to approved institutions.

DISCUSSION

GEORGE A. WORKS, Ed D., Chicago. Every active accrediting agency is faced by the local administrator who wishes it to protect him against his lack of vision, energy or courage and to give him guidance in details for which he and members of his staff should assume full responsibility. An accrediting agency should resist pressure of this character. Advice may be freely given, but the decisions should be made by those who are in immediate charge of the institution. No accrediting agency can take the place of ability, courage and vision on the part of those administratively responsible for a higher institution, and it should never attempt it. This means that as long as boards of control and executives, owing to a lack of vision or for ulterior purposes misuse their responsibilities the police function should be at hand as a means of protecting society. The third point relates to the substitution of qualitative standards for quantitative ones. Dr Zook called attention to the recent change made by the North Central Association in the substitution of its present statement of policy for its former standards. The emphasis of the latter was on quantitative requirements mechanically applied. The changed procedure has given a large share of the member institutions of the association a new attitude toward growth and development, a change that is distinctly for the better. But how Dr Zook, in Washington, was able to hear the "sigh of relief" that went up from colleges in the North Central territory and not at the same time hear the groans that arose immediately thereafter, when it was discovered that the new accrediting procedures involved a great deal of work is beyond my comprehension. In no quarter were these groans more audible than in the corner occupied by the medical institutions that were constituent parts of member institutions. As far as to why this change has come about so far as the member institutions are concerned, in their attitude toward the Association. It is due to the fact that there are no longer fixed standards mechanically applied, but we endeavor over a period of time to develop a pattern of every institution that we have in our membership. We don't attempt to say that the institution will be deprived of its membership or refused admission to the association on the basis of any single item or any two or three items, but we say on the basis of the picture it presents as a whole in comparison with the membership of the association. None of these are fixed because as the member institutions increase their expenditure per student that raises the hundred percent. What were regarded as minimum standards by the association came to be thought of by many members as maximum standards, and once an institution was in the association it had reached the haven of rest and no further progress was necessary. The institution that goes to sleep for two or three years finds that the majority of the membership has in that period been moving forward therefore it has lost ground and its membership in the association may be jeopardized. That fact alone plus the greater care with which we arrive at our data have completely changed the attitude of most of the members toward membership in the association.

REV. ALPHONSE M. SCHWITALLA, St. Louis. The method of antithesis that Dr Zook has employed labors to some extent from its own limitations. It stresses the north and south

poles and is apt to make one forget that there is an equator somewhere. Is it correct to stress an antithesis in the accrediting of institutions of higher learning by saying shall the accrediting be done by the profession or by the schools? There is a third possibility. It can be done by both. It can be done also by that other element that stands on the outside of the strictly accrediting process, namely the state boards. So, as I see it the accrediting that is now going on is an example to other agencies which have thus far not as yet used this technique. I think that the Council on Medical Education and Hospitals has introduced a new feature into the concept of the accrediting of higher institutions by stressing in its first pronouncement that the accrediting will not be done by the profession alone nor by the schools alone nor by the state boards alone but will be done by all those agencies interested in medical education. Now what is the unit of self determination that shall accredit the schools of medicine? I like to place the profession of medicine in the center of the picture with the educational activities that are proper to that profession on one side with the social relations of that profession on the other. The important thing in the picture is that the profession of medicine gives and gets stimulation from the adjoining neighbors and the integration of those factors is done by the profession of medicine rather than by the schools and in that I am by no means weakening my position I hope as an educator. But I am recognizing what Dr Zook and Dr Works have both stressed that after all the test of the educative process is going to be whether or not the product achieves the objective. We are in medical education not for the purpose of simply educating. We are in education for the purpose of achieving a product an end and that objective is the medical man who goes out to do his life work in our present social world.

DR. J. N. BAKER, Montgomery, Ala. I speak from the standpoint of the licensing boards represented in this body. If our problem were only that of dealing with orthodox graduates it would be simple, but there are many different varieties that appear before licensing boards clamoring to treat diseases of human beings. There is our great problem. I have felt that if there were any defect in our medical schools, it was that they were so intensely absorbed with the individual problems of teaching that sometimes they lost sight of the difficult problems confronting those entrusted with medical licensure. It is a joining of hands of three agencies, the medical profession the Association of American Medical Colleges and the licensing boards and the center of that picture should be the medical profession. Only with the coordinated effort and the integration of the three bodies that are so deeply interested in medical education and in seeing that the right sort of product is run through the schools to serve the general public will our object be attained.

Consistency versus Chaos in Medical Education and Licensure

DR. WALTER L. BIERRING, M.D., Des Moines, Iowa. All of the approved seventy-six medical schools in the United States and Canada have the same classification, yet a large gap is clearly evident between the different institutions. This is specially noted in the lack of unity in the general course of training. There is a further lack of coordination between the premedical and the medical sciences, and the relation of these courses to the clinical studies. An understaffing of the fundamental departments frequently exists with undue emphasis on clinical courses, particularly, in the medical and surgical specialties.

The American Board of Ophthalmology was organized in 1916 and of Otolaryngology in 1923, followed in 1927 by the formation of the American Board of Obstetrics and Gynecology, and of Dermatology and Syphilology in 1929. As other specialties began steps toward forming similar qualifying boards the need was recognized for some central agency or supervising body such as the Council on Medical Education and Hospitals of the American Medical Association for the purpose of coordinating graduate education and the certification of specialists in the United States and Canada. At the Milwaukee session of the American Medical Association in 1933, a resolution was adopted by the House of Delegates author-

izing the Council on Medical Education and Hospitals to formulate standards of administration in general based on those of the four specialty boards previously organized and to recognize new boards meeting these standards. To avoid duplication of effort as well as to coordinate the work of the several boards and other interested groups, it was deemed advisable to create an Advisory Board for Medical Specialties, which should be representative of each organization concerned. This advisory board began to function in February 1934. Since that time the American Boards of Pediatrics, Psychiatry and Neurology, Radiology, Orthopedic Surgery and Urology have been organized and officially recognized. The organization of the American Board of Internal Medicine is practically completed and the formation of the American Board of Surgery and of Pathology are making rapid progress, this within three years after this movement was inaugurated at Milwaukee. Special boards in the twelve recognized specialties will be established and hereafter only such candidates will be certified as have completed the required course of special training and been satisfactorily qualified in the particular specialty. There will be fewer medical specialists in the future, but those who *qualify will deserve the designation, for they will have passed the scrutiny of their peers.* Thus again it has come to pass that the medical profession has solved another of its important problems.

To cast a glance into the future a fact stands forth as having special implication for medical education: the restriction and higher qualification of the different medical specialists. In consequence of this and other evident tendencies the practitioner is being restored to an honorable place in the practice of medicine. It seems rather well established that only 15 per cent of those who become ill will require the services of a specialist, and thus 85 per cent of those who are sick as well as a large proportion of those who are well will come within the service of the general practitioner. This constitutes a distinct challenge to the educational forces that entails a number of distinct reforms in medical education which may be more clearly defined after the completion of the present resurvey of American medical schools. There appears to be a general objective of simplifying plans of instruction and a subtle change has come in the type or quality of medical learning, coincident mainly with the extension of our natural powers by mechanical devices. The erudite physician of another day seems to be passing. There is a growing feeling that medical education is tending in the direction of impersonality and that it is necessary to bring the patient again to the center of the medical student's interest. Premedical education as a prerequisite for the medical curriculum is regarded by many as far too technical. There is great need of reorientation of subject matter in the preliminary sciences. If we are correct in our conception of the sphere of service of the future practitioner, there is need of much reform in the training of the "basic" doctor.

DISCUSSION

DR. J. N. BAKER, Montgomery, Ala. During the chaotic early days of the present century, when diploma mills were plying their nefarious trade with reckless abandon, the licensing boards in each state took their tasks seriously, thereby making a substantial contribution to the purging processes of the Council on Medical Education and Hospitals and the Association of American Medical Colleges. Today, so satisfactory are the two last groups performing their tasks, that licensing boards appreciate the needlessness, so far as orthodox practitioners are concerned, of further written tests on their part. In short, were it not for the harassing hurdle of heterodoxy our problem would now be largely reduced to one of enforcement and the application of disciplinary measures. Unfortunately, problems in licensure cannot yet be solved by so simple a formula. Because of a general apathy or indifference or both on the part of the public and legislators toward elevated standards of licensure for those presuming to handle human ailments, various sorts of political compromises within the states still occur. Medical licensure being primarily a technical and professional problem, the medical profession, throughout this long struggle, has been out in the forefront, battling for the people's protection through a maintenance of high stand-

ards. Undoubtedly the zeal of the medical profession, spurred on by the apparent righteousness of its cause, has on many occasions been misconstrued by legislative bodies as acts of sheer selfishness. It seems difficult for the public to grasp the basic significance of legislative protection in the application of the healing arts and the fact that compromises with substandard training in this realm are not in the interests of sound public policy. The solution of most of the difficulties now being encountered seems to lie in education—education disseminated broadcast and wide through all strata of society as to the necessity for adequate scientific training before any one may be permitted, by law, to traffic in human life.

The State University and Professional Education

ARTHUR C. WILLARD, Urbana, Ill. It seems necessary to limit my discussion to professional education which is continued beyond the baccalaureate degree. In this educational area in recent years the yearly statistics on enrolments and graduates in typical fields have run about as follows: General postgraduate schools beyond the bachelor's degree, 54,000 students; 17,000 masters' and 3,000 Ph.D. degrees. Law schools granting law degrees, 21,000 students and 5,400 graduates. Medical schools granting degrees in medicine, 22,000 students and 5,000 graduates. It is probably reasonable to assume that upward of 100,000 students are enrolled in graduate and professional schools and that between 14,000 and 15,000 graduates issue from these schools yearly, to say nothing of the 17,000 masters' degrees secured after only one year of postgraduate work.

The state universities, at least those which derived from the land grant college act of 1862, the Morrill act and subsequent acts of the federal congress, seem to have been conceived with the idea of providing a college education, largely at public expense in every state and territory. The existence or non-existence of private institutions in the same areas had nothing whatever to do with the matter. The industrial development in agriculture and the mechanical arts demanded scientific knowledge of a more technical or applied type than could then be secured in the existing institutions of college grade. It was a recognition of the need of professional training for industry. If college education, more or less at public expense, could be provided for farmers and mechanics, why not also for doctors, lawyers, bankers, teachers and many other groups concerned with our social, economic and industrial life? A tremendous expansion in college and university education has taken place in this country during the last half century on the assumption that more of everything was needed, from steel rails to professional education. Today any accredited high school graduate in any state or territory can secure a college education at practically little more expense than the actual cost of living at the state university. Free tuition scholarships are provided liberally at most state universities, for example at the University of Illinois about 2,500 such scholarships are available. The youth of our country has welcomed this opportunity and more than a million maybe a million and a quarter, of them attend our colleges and institutions of similar grade. Any one of these accredited high school graduates who can satisfy the requirements for a bachelor's degree is either already on his way into a profession or else is a potential candidate for further postgraduate work. In consequence of this growing popular interest in education at all levels the demand for education at the professional and graduate school level is raising many questions which are complicated in state universities by the fact that public funds are being spent for the personal benefit of a very small percentage of the population. The selection of these individuals is a matter of great importance since the only justification for spending public funds must always be found in the benefits or services returned to the public. I am convinced that we consider too few factors or qualifications in admitting students for graduate or professional study in our state universities. Mental, moral and physical qualities of a high order are necessary and should be demanded of every candidate for professional education. On the other hand the candidate should know as much as possible about the past and current conditions as well as future prospects in the field of his choice before he enters on his professional education.

I am not in favor of quotas to limit enrolment in state universities but I am in favor of professional societies keeping

in close touch with the professional schools and in rendering advisory services relating to their problems. I am also in favor of the maintenance of the highest educational and ethical standards in selecting students and preparing graduates to enter the various professions. The activities of the American Medical Association and the American Bar Association in the fields of professional education and practice have inspired other professional groups to undertake similar surveys for the purpose of advancing their professional interests and standards of education and practice.

DISCUSSION

EUGENE A. GILMORF, LL.B., Iowa City. While there is a tendency to push strictly professional education more and more into the graduate levels where undoubtedly most of it ought to be, we are still a considerable distance from this ideal. A university is the institution best fitted to provide adequate and liberal professional education, either at the undergraduate or the graduate level. Professional education can, to be sure, be achieved quite apart from a university. This professional education apart from a university is, however, usually narrow and excessively utilitarian in scope and is dominated by direct vocational objectives. The practitioner schools, which were the first substitute for apprentice training, were once held in high esteem as the most efficient means for professional education. They probably are still so held by some. Indeed, a rather vigorous survival of this esteem may even yet be found although the training has become associated with a university and may have become an integral part of a university. This survival manifests itself quite vigorously whenever it is proposed to reduce the time devoted to clinical work or to make any omissions from the overcrowded list of specific subjects about which it is thought the prospective doctor should have knowledge or to substitute for laboratory work in the medical school carried on under a doctor general research in the basic sciences carried on under a nonmedical man in the laboratories of the university. That there is still a preference in certain areas for professional education apart from a university is shown by the fact that, of the 193 law schools now operating, seventy-nine have no university connection. The medical profession is more fortunate (or unfortunate depending on one's point of view). Before the great housecleaning in medical education, there were a considerable number of medical schools not associated with a university. Of the present sixty-seven approved schools in the United States, fifty-nine have university association, more or less intimate. I have no doubt that professional education in law and medicine and in every other profession of a learned sort should be carried on as an integral part of a university and that there should be a very close relation between the professional group and the university group. In addition to the enrichment and improvement of medical science on its technical side through this association, there should come substantial progress toward the goal of a professional education in medicine which is less vocational and more liberal, and at the same time more efficient.

(To be continued)

RADIO BROADCASTS

The American Medical Association broadcasts over WEAf, the Red network instead of the Blue, as formerly, and certain additional stations of the National Broadcasting Company at 5 p. m. eastern standard time (4 o'clock central standard time, 3 o'clock mountain time, 2 o'clock Pacific time) each Tuesday, presenting a dramatized program with incidental music under the general theme of Medical Emergencies and How They Are Met. The title of the program is 'Your Health'. The program is recognizable by a musical salutation through which the voice of the announcer offers the toast "Ladies and gentlemen, your health!" The theme of the program is repeated each week in the opening announcement, which informs the listener that the same medical knowledge and the same doctors that are mobilized for the meeting of grave medical emergencies are available in every community day and night, for the promotion of the health of the people. Each program will include a brief talk dealing with the central theme of the individual broadcast.

Red Network—The stations on the Red network of the National Broadcasting Company are WEAf, WEEI, WTIC, WJAR, WTAG, WCSH, KYW, WFBR, WRC, WGY, WBEN, WCAE, WTAM, WWJ, WMAQ, KSD, WHO, WOW, WDAF.

Pacific Network—The stations on the Pacific network are KGO, KPO, KFI, KGW, KOMO, KHQ, KFSD, KTAR.

Network programs are broadcast locally or omitted at the discretion of the local station. The lists indicate stations to which programs are available.

The next three programs are as follows:

March 31	Hay Fever and Asthma	Morris Fishbein M.D.
April 7	Let Your Doctor Decide	R. G. Leland M.D.
April 14	Summer Camps	Morris Fishbein M.D.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ARIZONA

Society News—At the March meeting of the Maricopa County Medical Society, Phoenix, speakers were Drs. Dudley T. Fournier on 'Nonconvulsive Toxemia of Pregnancy', Benjamin Herzberg 'Modern Aspects of Treatment of Eclampsia', and Clarence B. Warrenburg, 'Hormone Therapy in Gynecology'. All are from Phoenix.—The ninth annual meeting of the Arizona Public Health Association and the short school for public health workers will be held at Tucson April 20-22.—Mrs. Kitty Ives Coleman has been employed on a temporary basis by the Arizona State Medical Association to assist Dr. Delamere F. Harbridge, Phoenix, secretary of the association. She will also serve as secretary for the Maricopa County Medical Society and the Maricopa County Library Board.

CALIFORNIA

Hospital News—Kern County supervisors, with counsel from eleven other counties as amicus curiae, have appealed to the supreme court the ruling of a lower court and the court of appeals enjoining Kern County supervisors from admitting nonindigent or pay patients to the county hospital.

State Association News—The sixty-fifth annual meeting of the California Medical Association will be held in Coronado, May 25-28. Guest speakers will include Drs. Campbell P. Howard, Montreal, Canada, Jacob J. Singer, St. Louis, and Franklin G. Ebaugh, Denver. Sunday, May 24, there will be two pathologic conferences on cancer, a clinical x-ray conference, a symposium on cancer for general practitioners, and a joint conference of association standing and special committees. The association has declared that x-ray and laboratory services cannot be divided into technical and professional divisions. It holds that x-ray diagnosis, laboratory services administering of an anesthetic and hydrotherapy constitute the practice of medicine. A Hall of Medical Science, containing 22,000 feet of exhibit space, was opened at the San Diego Exposition March 7, under the direction of the San Diego County Medical Society and the state medical association. Thirty-five exhibits are installed, including one of 500 square feet prepared by the American Medical Association.

Society News—Among others William Fowler of the California Institute of Technology, Pasadena, discussed 'Recent Developments in Physics' before the Los Angeles County Medical Association, March 19.—The annual meeting of the California Tuberculosis Association will be held in Sacramento April 3-4.—Dr. Francis D. Coman, Baltimore physician to the first Admiral Byrd expedition to the South Pole, discussed 'The Practice of Medicine in Little America' before the Hollywood Academy of Medicine, March 19.—At a meeting of the Society of Ophthalmology and Otolaryngology of Los Angeles, March 23, Dr. William P. Wherry, Omaha, discussed 'Postgraduate Education in Otolaryngology'. A viewpoint of the Examining Board for Otolaryngology, Dr. William L. Benedict, Rochester, Minn., 'Surgical Conditions of the Orbit', and Dr. Dean M. Lierle, Iowa City, 'Focal Infection in Arthritis'—Dr. John Alexander, Ann Arbor, Mich., addressed a joint

meeting of the tuberculosis section of the Los Angeles County Medical Society and the Clinical and Pathological Society, March 27 on "Advances in the Surgical Treatment of Thoracic Disease"

CONNECTICUT

Low Infant Mortality Rate—Connecticut recorded an infant mortality rate in 1935 of 43.2 deaths in the first year of life per thousand living births. There were 944 deaths reported and 21,860 living births. This is the lowest rate on record for the state.

The Ferris Lecture—Davenport Hooker, Ph.D. professor and head of the department of anatomy, University of Pittsburgh School of Medicine, delivered the third Harry Burr Ferris lecture in anatomy at Yale University, New Haven in the Sterling Hall of Medicine February 19 on "Early Fetal Movements in Mammals."

Society News—Dr. Newton E. Wayson of the U. S. Public Health Service discussed "Leprosy—Early Diagnosis in Children" before the Yale Medical Society March 11.—Dr. Wilbur A. Sawyer, director of the International Health Division of the Rockefeller Foundation, New York, lectured in New Haven, March 13 under the auspices of the local chapter of Delta Omega, honorary public health society. His address was entitled "The Evolution of Our Ideas of Yellow Fever Epidemiology."—Dr. William B. Castle, Boston, addressed the Tri-City Medical Society (Norwich, New London and Willimantic), February 6, in Norwich, on "Recent Advances in Blood Diseases."

FLORIDA

New Health Unit at Hollywood—A public health unit has been established in Broward County with Dr. Paul G. Shell formerly of Marianna in charge. The new unit will be maintained by Lauderdale, Hollywood and Broward County, their combined contribution of \$5,000 to be matched by a similar amount from the state and federal governments. Headquarters will be in Hollywood.

GEORGIA

Dr. McCord Named Professor—Dr. James R. McCord, professor of gynecology and obstetrics at Emory University School of Medicine, Atlanta, on a part time basis has been named to a full time position. It is reported Dr. McCord graduated from Jefferson Medical College, Philadelphia, class of 1909. For several years he has been conducting extension courses in obstetrics throughout the United States in his capacity as senior medical officer and special representative of the Children's Bureau of the U. S. Department of Labor.

Society News—Drs. William Carter Smith and Launcelot Minor Blackford gave a paper before the Fulton County Medical Society, Atlanta, March 19 on "Syphilitic Aortic Insufficiency." Dr. Hulett H. Asken read a paper entitled "Rectal Fistula and Its Treatment" before the society, March 5.—The Fifth District Medical Society was addressed in Atlanta, March 27, by Drs. John C. Burch, Nashville, on "Diagnosis and Classification of Menstrual Disorders." William Perrin Nicolson, Jr., Atlanta, "Carcinoma of the Breast." Murdoch S. Egan, Atlanta, "Partial Esophagectomy for Cancer." and Virgil P. W. Sydenstricker, Augusta, "Recent Developments in the Problem of Pellagra."—The Muscogee County Medical Society was addressed in Columbus, February 13, by Drs. William W. Anderson and Milus K. Bailey, Atlanta, on "Chest Conditions in Infants and Children and Problems in Pediatric Urology, respectively."—At a meeting of the Fourth District Medical Society in Griffin, February 12, speakers included Drs. Joseph C. Massee, Atlanta, "Pneumothorax and Other Measures in Treatment of Tuberculosis" and George L. Walker, Griffin, "Modern Treatment of Pneumonia."

ILLINOIS

Meeting on Stream Pollution—Health directors and sanitary engineers representing Illinois, Iowa, Minnesota, Missouri and Wisconsin attended a meeting in Chicago, March 10, to consider a program of stream pollution abatement in the upper Mississippi drainage basin. State health directors in each of the states named have signed an agreement to cooperate in this program.

Annual Tumor Clinic—The sixth annual tumor clinic will be held at the Veterans Administration Facility—Edward Hines, Jr. Hospital, Hines, April 9. The clinic will begin at 2:30 in the afternoon under the direction of Dr. Max Cutler, Chicago, and staff officers of the tumor clinic of the hospital. Following dinner in the evening, Dr. Gordon B. New Rochester, Minn., will be the guest speaker.

CHICAGO

Interns' Banquet—The Cook County Hospital Interns Association will hold a banquet April 1 at the Congress Hotel at 7 p. m. Dr. Morris Fishbein will be the guest speaker. Mail or telephone reservations to R. A. Lufvendahl, 2400 South Dearborn Street, Victory 3520.

Dr. Grinker Appointed Chairman of Department—Dr. Roy R. Grinker, head of the division of psychiatry at the University of Chicago, has resigned to become chairman of the department of neuropsychiatry at Michael Reese Hospital. In accordance with plans of the hospital for the development of investigative interest in nervous and mental diseases, clinical and laboratory facilities for research in neuropsychiatry are to be opened for Dr. Grinker's purpose. Application for a research fellowship in neuropsychiatry beginning July 1 should be made to him.

Society News—At a meeting of the Chicago Ophthalmological Society, March 16, Dr. Edward V. L. Brown spoke on "Apparent Increases in Hyperopia Up to the Age of Nine," and Drs. Thomas D. Allen and Sanford R. Gifford discussed "Surgical Treatment of Retinal Detachment."—The Chicago Society of Allergy was addressed March 16 by Drs. Milton B. Cohen, Cleveland, and Karl D. Figley, Toledo, on "Changes in Growth, Maturity and Mineralization Associated with Allergy," and "Iodized Oil in Intractable Asthma," respectively. Dr. Isadore Pilot discussed "Urticaria Due to Wittes Peptone."—Dr. Charles C. Higgins, Cleveland, addressed the Chicago Urological Society, March 26, on "Experimental Production and Solution of Urinary Calculi with Clinical Application and End Results."

INDIANA

Symposium on Pediatrics—The Indianapolis Medical Society devoted two meetings, March 10 and 17, to a symposium on pediatrics. A discussion at the first session dealt with "Preventive Measures in Pediatrics" under the direction of Dr. Matthew Winters. Speakers were Drs. Herbert F. Call, Russell R. Hippensteel, Louis H. Segar and Howard B. Mettel. Clinical demonstrations by members of the staff of Riley Hospital made up the program for the second session.

Society News—Drs. Robert M. Moore and Cyrus Clark, Indianapolis, discussed coronary disease before the Montgomery County Medical Society, February 20.—A symposium on oral pathology and its relation to internal medicine will be presented before the Indianapolis Medical Society, March 31, by Drs. Jeane Thayer, Waldo James O. Ritchey and Rollin H. Moser. Dr. Harry L. Alexander, St. Louis, discussed "Principles of Diagnosis and Treatment of Allergic Disorders" before the society, March 3.—Dr. Robert M. Moore, Indianapolis, addressed the Northeastern Indiana Academy of Medicine at Kendallville, February 27, on coronary sclerosis.

Memorial to Physician—Funds are being solicited to establish a memorial in honor of the late Dr. William L. Hughes, Indiana Harbor. The committee in charge believes it is both fitting and proper that the life and services of Dr. Hughes be commemorated in some manner, and thus continue the memory of his splendid example of self sacrifice in and for the community. A statement issued by the committee reads: "We believe Dr. Hughes did a great work, especially for children in a most unselfish manner, and no one was too poor to be denied his service and ability." Mr. William J. Murray, judge of the criminal court at Crown Point, is chairman of the committee. Rev. O. P. Manker is secretary and D. L. Mitchell, treasurer. Dr. Hughes died February 18.

KANSAS

Health at Kansas City—Telegraphic reports to the U. S. Department of Commerce from eighty-six cities with a total population of 37 million for the week ended March 14 indicate that the highest mortality rate (24.3) appears for Kansas City, and the rate for the group of cities as a whole 14.1. The mortality rate for Kansas City for the corresponding period last year was 14.2 and for the group of cities 12.2. The annual rate for eighty-six cities for the eleven weeks of 1936 was 13.7 as against a rate of 12.9 for the corresponding period of the previous year. Caution should be used in the interpretation of these weekly figures as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate.

Society News—At a meeting of the Ford County Medical Society in Dodge City, February 14, speakers were Drs. Laurence S. Nelson, Salina, on "Wertheim Interposition" and

George B Kent, Denver, "Surgical Management of Malignant Lesions of the Colon and Rectum"—Dr Raymond J Dittich, Fort Scott, addressed the Labette County Medical Society in Parsons, January 29, on "Treatment and Cure of Bone Infections"—The Washington County Medical Society was addressed in Washington, February 4, by Drs Arthur R Bryant and Robert W Taylor, Beatrice, Neb, on "External and Middle Ear Infections" and "Common Ocular Pathology with Suggestions for Treatment" respectively—At a meeting of the Tri-County Medical Society (Harvey, Marion and McPherson) in McPherson, February 12 Dr Ralph Bowen, Oklahoma discussed "The Practical Management of Allergic Problems as Seen in General Practice", Dr Clinton K Smith, Kansas City, "Prostatic Hypertrophy and Electrossection of the Prostate" and Dr Arthur Lloyd Stockwell Kansas City, "Practical Considerations in Spinal Anesthesia"

MASSACHUSETTS

Physicians Meet with Legislators—Members of the Massachusetts legislature from Worcester and vicinity were entertained at a dinner meeting by local physicians, February 21 Following the dinner, Dr William F Lynch president of the Worcester District Medical Society, introduced Dr Arthur W Marsh, Worcester, a member of the legislative committee of the state society, as master of ceremonies Various bills bearing on medicine and public health were discussed and Dr Charles E Mongan, Somerville president of the Massachusetts Medical Society, was a speaker

Society News—Dr Frank H Lahey, Boston, addressed the Arlington Doctors' Club March 10, on "Diseases of the Thyroid and Parathyroids"—Dr Kendall Emerson, New York, will speak at a joint meeting of the Massachusetts Tuberculosis League and the Hampden County Tuberculosis and Health Association in Springfield April 8—At a meeting of the Greater Boston Medical Society, January 7, speakers included Dr Boris E Greenberg on "Visualization of Postgonorrheal Complications"—Dr Elliott C Cutler, Boston will address the William Harvey Society of the Tufts College Medical School, April 10, on "War Surgery"—Dr Alexander Lambert formerly professor of clinical medicine, Cornell University Medical School, addressed the society, March 13, on "Therapeutics of Drug Habits"—At a meeting of the New England Heart Association in Worcester, February 24, Drs Oliver H Stansfield and Edward J Halloran discussed Effects of Contagious and Infectious Diseases on the Heart", Dr Frank B Carr, 'Acute Benign Pericarditis,' and Dr John J Dumphy, 'Coronary Symptoms in Pernicious Anemia'—The New England Physical Therapy Society was addressed in Boston February 19 by Leslie L Campbell, PhD, for many years professor of physics Simmons College, Boston "Elementary Physics of Galvanism," and Drs Frederick H Morse, Hiram Houston Merritt and Claude L Payzant, "Clinical Uses of Galvanic Current"

MICHIGAN

Personal—Dr John L Burkhart for many years city health officer of Big Rapids, has been appointed postmaster—Dr Robert F Berry has been appointed superintendent of Morgan Heights Sanatorium, Marquette

Society News—Dr John A Hookey, Detroit, addressed the Monroe County Medical Society, February 20, in Monroe on "Treatment of Eczema"—At a meeting of the Jackson County Medical Society in Jackson February 18 Dr Robert H Durham discussed 'The Protein Manifestations of Thyroid Insufficiency'—Speakers before the Detroit Otolaryngological Society, March 18 were Drs Derrick T Jr and Harris H Vail both of Cincinnati, on "Ophthalmic Origin of Headache" and 'Practical Considerations of Vidian Neuralgia' respectively

New Dean at Wayne University—Dr Raymond B Allen, associate dean of graduate studies Columbia University College of Physicians and Surgeons New York, has been named dean of Wayne University School of Medicine, Detroit He succeeds Dr Walter H MacCraken, who resigned last year Dr William J Stapleton Jr, who has been acting dean of the school, will become associate dean when Dr Allen takes over his duties, May 18 Dr Allen is 33 years of age He graduated from the University of Minnesota Medical School Minneapolis in 1928

The So Called "Filter System" for Handicapped Children—On January 28 eighty-two counties all but one in the state had reported the creation of a county medical society public relations committee, a medical filter and an economic

filter in accordance with an agreement between the Michigan State Medical Society, the Michigan Probate Judges Association and the Michigan Hospital Association Under this system, afflicted and crippled children of the state will be examined and their economic status determined Those able to pay will be 'filtered' back to their family physicians, physicians caring for children unable to pay will be paid with funds from a specific appropriation by the state The medical filter is a committee composed of three physicians selected by the county medical society to give a thorough physical examination to applicants for hospitalization, while an investigating committee representing the probate court and the county medical society will examine the applicants' economic status No applicant will be committed by a probate judge unless he has received the proper certificate from an authorized member of the committee that the case is urgent The state medical society was instrumental in drafting the filter system, which was adopted after it was made known that the funds appropriated by the state to care for afflicted and crippled children were running low The law specifically states that physicians should be paid, but except for a brief period of a few weeks the work has been done free of charge on account of the lack of appropriated funds The state has sufficient money to pay for this care, but the funds were not specifically allocated The chief cause for complaint was the looseness of the system, which permitted any one to receive medical care at state expense, with the physician donating his services, it was stated

MINNESOTA

Mayo Foundation Lectures—Mr L R Broster, London, gave a lecture at the Mayo Foundation Rochester, February 27 entitled Eight Years Experience on the Surgery of the Adrenal Gland with Reference to the Adrenogenital Syndrome" Dr Arthur G Sullivan, Madison Wis, lectured, February 10, on Medicolegal Problems in Medical Practice"

Abortionist Sentenced—Mrs Ida Bare pleaded guilty in the district court of Ramsey County, March 4, to a charge of performing an illegal operation and was sentenced to a term of not to exceed two years at hard labor at the Woman's Reformatory at Shakopee The operation resulted in the almost instantaneous death of the patient, it was stated

Memorial to Dr Johnson—Plans are under way to establish a memorial to the late Dr Herman M Johnson, Dawson Members of the Minnesota State Medical Association will be asked to contribute to a fund, which, it is expected, will be used to maintain a lectureship in medical economics Dr Johnson, who died last year, was president of the state association and medical superintendent of the Dawson Surgical Hospital He was instrumental in passing the basic science law in Minnesota In 1926 and 1927 and from 1929 to 1935 he was a member of the House of Delegates of the American Medical Association

NEW JERSEY

Society News—Dr David W Kramer, Philadelphia, addressed the Gloucester County Medical Society Woodbury, February 21 on Advances in Treatment of Peripheral Vascular Disease"—Drs Oswald S Lowsley and Francis P Twinnem, New York, addressed the Bergen County Medical Society, Englewood, March 10, on 'Some Aspects of Prostatic and Renal Surgery' and 'Treatment and Prevention of Urinary Calculus' respectively Dr William G Herrman, Asbury Park a vice president of the Medical Society of New Jersey, spoke on activities of the state society

NEW MEXICO

Society News—At a meeting of the Grant County Medical Society, Silver City, in January case reports were presented, among others by Drs Nathaniel D Frazin and Russell C Lane, Silver City, on encapsulated tumor of the lung, Marcellus McCreary Fort Bayard abscess following antisyphilitic injection followed by negative Wassermann reaction Dr Frazin also presented a case of tuberculous infection of the metatarsal bones

New Crippled Children's Hospital—WPA funds have been assured for construction of a new hospital for crippled children at Hot Springs and ground was broken at a recent ceremony, *Southwestern Medicine* reports Work is to start immediately on the hospital which is to cost about \$400,000 It is to have a capacity of eighty-four beds All but one building will be of one story There will be an outdoor swimming pool connected with an indoor treatment pool

NEW YORK

Typhoid at County Home—Three persons had died and eleven others were ill in an outbreak of typhoid at the Genesee County Home, near Batavia, newspapers reported March 15. It was suspected that the source of the infection was creek water used for drinking.

Dr Butler Appointed to State Hospital Service—Dr Ethan Flagg Butler, Elmira, has been appointed chief thoracic surgeon for the state tuberculosis hospital service. After the opening of the Biggs Memorial Hospital, Ithaca, Dr Butler will make his headquarters there but for the present he will divide his time between the Oneonta and Mount Morris hospitals. Dr Butler has at various times served on the staffs of Walter Reed General Hospital, Washington, D C, Bellevue Hospital, New York and Robert Packer Hospital, Sayre, Pa. He was president of the American Association for Thoracic Surgery in 1931.

New York City

WPA Funds for Venereal Disease Campaign—An appropriation of \$100,000 has been approved by the Works Progress Administration to be used to aid the department of health in a campaign to control venereal disease. The funds will provide equipment and supplies and work for 127 persons of whom ninety-seven are physicians and nurses. It was said a pavilion at the Kingston Avenue Hospital, Brooklyn, has been set aside by the department of hospitals for treatment of persons with venereal disease and a special bureau for control of these diseases has been established in the health department under the direction of Dr Charles Walter Clarke.

Salmon Memorial Lectures—The Salmon Committee on Psychiatry and Mental Hygiene announces that the fourth series of Thomas William Salmon Memorial Lectures will be presented by Dr Samuel T. Orton, professor of neurology and neuropathology, Columbia University College of Physicians and Surgeons, April 10, 17 and 24 at the New York Academy of Medicine. The general subject of the lectures will be 'Developmental Disorders of the Language Faculty and Their Psychiatric Import'. Individual lectures will be: April 10, 'Language Losses in the Adult as the Key to the Developmental Disorders in Children'; April 17, 'The Syndromes of Disorder in the Development of Language'; and April 24, 'Treatment and Psychiatric Interpretation'.

Edgar Sydenstricker Dies—Edgar Sydenstricker, scientific director of the Milbank Fund and for many years chief statistician of the U S Public Health Service, died March 19 of cerebral hemorrhage, aged 54. He was born in China and came to the United States in 1896. After graduating from Washington and Lee University in 1902, Mr Sydenstricker was a teacher and newspaper man for several years. From 1908 to 1915 he directed industrial community studies for the U S Immigration Commission and the U S Commission on Industrial Relations and in the latter year was appointed to organize the statistical work of the public health service. He was one of the organizers of the health section of the League of Nations in 1923 and 1924. Since 1925 Mr Sydenstricker had been in charge of research and public health activities of the Milbank Fund and in April 1935 became administrative head with the title of scientific director. He was a member of President Hoover's Committee on Social Trends in 1931-1932 and of President Roosevelt's Committee on Economic Security in 1934-1935.

NORTH CAROLINA

Society News—Dr Hugh Cabot, Rochester, Minn., addressed the Forsyth County Medical Society, Winston-Salem, February 17, on 'Tumors of the Kidneys'. Speakers at a meeting of the Fourth District Medical Association in Wilson, February 11, were Drs Isaac H. Manning, Chapel Hill, on hospital insurance; Malory A. Pittman, Wilson, pelviphysiology; and Hugh A. Thompson, Raleigh, traumatic surgery.

OHIO

Personal—Dr Jonathan Forman, Columbus, has been appointed editor of the *Ohio State Medical Journal* to succeed Dr Leslie L. Bigelow, Columbus, who resigned in December. Dr Forman graduated from the old Starling-Ohio Medical College in 1913 and served on the faculty after the school was merged with Ohio State University College of Medicine. Dr Donald E. Yochem, Columbus, has been appointed medical director of the Cooperative Life Insurance Company of America.

Outbreak of Gastro-Enteritis—About 1,500 cases of gastro-enteritis were reported to the state department of health, February 20, from Coshocton. According to an investigation

made by Dr William P. Johnson of the health department, Columbus, symptoms were nausea followed by vomiting, cramps, diarrhea, slight fever, chilliness and aching. The victims recovered within from twenty-four to thirty-six hours. The city water was suspected of being the source, as no other common factor was found. However, samples sent to the state laboratory showed no evidence of contamination.

Society News—Dr Robert A. Lyon, Cincinnati, addressed the Clermont County Medical Society, Williamsburg, recently on advances in treatment of contagious diseases. Dr Stanley E. Dorst, Cincinnati, presented a paper on 'Specific Serum Treatment of Pneumonia' before the Hancock County Medical Society, Findlay, February 6. Dr Jay Arthur Myers, Minneapolis, addressed the Lorain County Medical Society, Lorain, February 11, on diagnosis and treatment of tuberculosis. Dr Charles M. Clark, Akron, discussed 'Infections of the Nose and Throat as Related to Diseases of the Lower Respiratory Tract' as guest of the Portage County Medical Society, Ravenna, February 6. Drs Louis Feid Jr and Charles R. Deeds, Cincinnati, addressed the Stark County Medical Society, Canton, February 4, on 'Uterine Bleeding' and 'Rectal Bleeding' respectively. Dr Chesterfield J. Holley, Wheeling, W. Va., discussed 'Significance of Anal and Rectal Pain' at a meeting of the Belmont County Medical Society, Bellaire, February 6.

PENNSYLVANIA

Flood Stricken Town Quarantined—The town of Sunbury, in the flood area, was placed under quarantine by the state health department, March 20, when ninety cases of scarlet fever, diphtheria, measles and chickenpox were reported. Three-fourths of the town was said to be under several feet of water with 4,000 persons homeless. Physicians, nurses and relief workers were said to be using motorboats, rowboats and being useless in the swift currents. National guardsmen barred all but relief workers from the town.

Society News—Dr Russell L. Haden, Cleveland, addressed the Cambria County Medical Society, Johnstown, March 12, on 'Study and Treatment of Anemia'. Dr Frank R. Hanlon, Wilkes-Barre, addressed the Northampton County Medical Society, Easton, February 21, on 'Management of Acute Erythema'. Drs Harry J. Robb, DuBois, and Roger E. Phillips, Philipsburg, among others, addressed a joint meeting of the Centre and Clearfield County medical societies in Clearfield, February 20, on 'Angina Pectoris and Coronary Occlusion' and 'Office Management of Diabetes' respectively.

Philadelphia

Annual Clinical Lectures—Mercy Hospital will present its fourth annual clinical lectures March 30-April 3, two each afternoon. Following are the speakers:

Monday	Drs Howard Childs, Carpenter	Value of Periodic Physical Examinations of Children
Tuesday	Drs Edward A. Schumann, DuBois	Difficult Labor
	Jackson, Philadelphia	Diseases of the Esophagus and Stomach—Endoscopically Considered
Wednesday	Drs Hermann Prinz, Common	Diseases of the Oral and Mucous Membrane
	David Riesman, Philadelphia	Diagnosis and Treatment of Early Circulatory Failure
Thursday	Drs Herbert L. Northrop, Philadelphia	Miscellaneous Highlights of Surgery
	Willard H. Kinney, Philadelphia	Urolithiasis
Friday	Drs Catherine Macfarlane, Philadelphia	Dysfunctional Uterine Bleeding
	Randle C. Rosenberger, Philadelphia	Diseases Now Considered as Due to Filtrable Viruses

Society News—Speakers before the Pathological Society of Philadelphia, March 12, were Drs Max B. Lurie on 'Mechanism of Immunity in Tuberculosis', The Role of Some Cellular and Acellular Factors; Lawrence W. Smith, 'Certain Pathologic Changes in the Heart in Scarlet Fever'; and Virgil H. Moon and David R. Morgan, 'Pathologic Features Following Shock with Delayed Death'. Dr Walter Freeman, Washington, D. C., addressed the Philadelphia Psychiatric Society, March 13, on 'Constitutional Factors in Relation to Mental Disease'. Three Pittsburgh physicians presented the program of the Philadelphia County Medical Society, March 25, on diseases of the thyroid. Dr William J. Fetter discussed incidence and diagnosis; Dr William L. Mullins, cardiac manifestations; and Dr John P. Griffith, surgical treatment. Drs Robert A. Kimbrough Jr. and Robert M. Shirey presented a 'Statistical Survey of Eclampsia' before the Obstetrical Society of Philadelphia, March 5. Dr Douglas P. Murphy spoke on 'Reproductive Characteristics of Families Having Malformed Children'. James L. Weatherman, A.M., and Charles Robb of the University of Pennsylvania Graduate School of Medicine, among others, addressed the Philadelphia Roentgen Ray Society, March 5, on 'Saturation Technique as a Procedure in Giving Radiation'.

RHODE ISLAND

Society News—Drs John T Farrell and James Murray Beardsley, Providence, addressed the Providence Medical Association March 2, on "Roentgenologic Differential Diagnosis of Nontuberculous Diseases of the Lung" and "Bronchiectasis" respectively. Drs Soma Weiss, Boston, and Russell S Bray addressed the association, February 3, on "Clinical Significance and Management of Syncope" and "Nontropical Sprue" respectively.—The Rhode Island Medical Society will hold its annual meeting June 3-4 at Providence.

Bills Introduced—S 179 proposes to grant liens to physicians, nurses and hospitals, treating persons injured through the fault of others, on judgments, settlements or compromises accruing to the injured persons by reason of their injuries. S 181 proposes to restrict the sale of those proprietary medicines and ordinary household remedies and drugs, to which the provisions of the pharmacy practice act do not now apply, to shops and stores specifically so licensed by the chief of the division of narcotic drugs and pharmacies. H 780 proposes to repeal the present law requiring the licensing of maternity hospitals and to enact in its stead a new law requiring maternity hospitals to be licensed annually by the state department of public health. The bill proposes that "any person who receives for care and treatment during pregnancy or during delivery or within ten days after delivery, any woman except women related to him or her by blood or marriage, shall be deemed to maintain a maternity hospital." No such license to conduct such a hospital can be issued by the department of public health until after careful investigation it finds the hospital premises to be in a fit sanitary condition. The department is to be given the authority to issue general regulations and rules for the conduct of all such hospitals. Every birth occurring in a maternity hospital must be attended by a legally qualified physician or midwife. H 795, to amend the laws relating to coroners and medical examiners, among other things proposes that on the passage of the bill "the terms and services of the several medical examiners now holding office shall be deemed to have ceased and terminated, and thereupon the attorney general shall appoint medical examiners." H 826 proposes to require, as a condition precedent to the obtaining of licenses to wed, both parties to proposed marriages to present certificates from licensed physicians that they are not afflicted with syphilis or in a stage of that disease that may become communicable.

WASHINGTON

Personal—Dr John W Darrough Everett, was recently appointed health officer of that city.—Dr John W Stevenson, Hoquiam, has been appointed health officer of Grays Harbor.

Society News—Dr Alexander B Hepler, Seattle addressed the Walla Walla Valley Medical Society, Walla Walla, March 12, on 'Urology from the General Practitioner's Viewpoint'.—Drs Charlton E Hagyard and Harry L Leavitt addressed the King County Medical Society, Seattle March 16, on 'Acute Pancreatic Necrosis' and 'Scoliosis' respectively.—Dr Paul G Flothow, Seattle, addressed the Clallam County Medical Society, Port Angeles, January 22 on the sympathetic nervous system.—Drs William H Goering, Tacoma and Ira O McElmore, Seattle, addressed the Cowlitz County Medical Society, Longview, February 11, on orthopedic surgery with reference to crippled children.—Dr Delmar F Bice Yakima president of the Washington State Medical Association addressed a joint meeting of the Whatcom and Skagit county medical societies in Bellingham, February 3 on state medicine.—Dr James M Bowers, Seattle presented a paper on diseases of the chest before the Yakima County Medical Society, Yakima, February 10.

WEST VIRGINIA

Society News—Dr William F Rienhoff Jr, Baltimore, addressed the Ohio County Medical Society, Wheeling January 31, on 'Surgical Treatment of Diseases of the Bronchi and Lungs'.—Drs Edward J Van Lier and Frederick R Whittlesey addressed the Monongalia County Medical Society, Morgantown, February 4, on 'Effect of Low Oxygen Tension on Movements of the Stomach' and 'Low Oxygen Tension in Disease' respectively.—The Central West Virginia Medical Society met in Sutton, February 27 with the following speakers all of Columbus Ohio: Drs Samuel D Edelman 'Preventive and Curative Measures in Diseases', Frank W Harrah 'Transurethral Resections of Vesical Neck Obstructions' and William B Morrison 'Diagnosis and Treatment of Carcinoma of the Stomach'.—Dr Claude C Coleman Richmond, Va, addressed the Harrison County Medical Society Clarksburg February 5, on diagnosis and treatment of brain tumors.

GENERAL

Prevalence of Meningitis—Three hundred and seven cases of meningococcic meningitis were reported to the U S Public Health Service during the week ended February 29, in the corresponding week of 1935, 154 cases were reported. Seven deaths had occurred and strict quarantine was imposed in Texarkana Texas, February 23, according to newspaper accounts. Eight deaths had occurred in Quincy, Ill, the Chicago Tribune reported March 17. Thirty cases were reported in North Carolina during January and February, with several deaths. Work was suspended at a coal camp in McCreary County, Ky, March 2, after two miners had died of meningitis. McCreary is in the southeastern section of the state near Harlan County, where a serious epidemic has occurred. In Charleston S C, forty-seven cases have been hospitalized at Roper Hospital, thirteen from the county, it was reported March 3. Several schools in the county were closed.

Society News—Dr Edwin M Neher, Salt Lake City, was chosen president of the Western Ophthalmological Society at the third annual meeting in Pasadena, Calif, January 25. Dr Frederick C Cordes, San Francisco, was named vice president, and Dr Andrew J Browning, Portland, Ore, secretary. The next annual session will be held in Denver, in connection with the summer course conducted by the Colorado Congress of Ophthalmology and the Colorado University School of Medicine in July 1937. Speakers at the recent meeting included Drs John E Weeks Portland Ore, on 'The Amblyopia of Arsenical Therapy', Harold F Whalman, Los Angeles, 'Hodgkins Disease of the Eye' and David O Harrington, San Francisco, 'The Optic Radiation in the Temporal Lobe, with Case Report of Perimetric Studies in Complete Removal of the Temporal Lobe'.—The American Association on Mental Deficiency will hold its sixtieth annual meeting at the Hotel Jefferson St Louis May 1-4. The Friday sessions will be devoted to general and sociological aspects of mental deficiency, while the Saturday sessions will be given over to psychologic and educational topics with stress on educational disabilities. Monday will be devoted to research activities, medical aspects and administrative problems in mental deficiency. Additional information may be obtained from the secretary, Dr Groves B Smith, Godfrey, Ill.—Dr James H Means, Boston was chosen president-elect of the American College of Physicians at the annual session in Detroit, March 5, and Dr Ernest B Bradley Lexington Ky, was installed as president. Vice presidents are Drs O H Perry Pepper, Philadelphia, David P Barr, St Louis and Walter L Biering, Des Moines. The next meeting will be in St Louis.

Medical Bills in Congress—*Changes in Status* S 2625 has passed the House extending the facilities of the Public Health Service to seamen on government vessels not in the military or naval establishments. H R 3629 has been reported to the Senate authorizing the acquisition of additional land for the use of Walter Reed General Hospital. *Bills Introduced* S 4310 introduced by Senator Black, Alabama, proposes to appropriate \$1,750,000 to erect, in the state of Alabama, a hospital for the diagnosis, care and treatment of neuropsychiatric patients entitled to hospitalization under the World War Veterans' Act as amended. H J Res 527, introduced by Representative O Leary, New York, proposes to make the facilities of the United States Marine Hospital at Stapleton, N Y available for World War veterans in Richmond County, N Y. H R 11826 introduced by Representative Hoepfel, California, proposes to reenact all laws in effect March 19, 1933 granting hospitalization and domiciliary care to veterans of the Spanish-American War, including the Boxer Rebellion and the Philippine Insurrection. H R 11827, introduced by Representative Secrest, Ohio, proposes to establish a Bureau of Veterans Affairs in the Department of the Treasury and to revise generally the laws relating to veterans. The bill among other things would provide domiciliary and hospital care including medical treatment, to all retired officers and enlisted men of the United States army, navy, marine corps or coast guard who served in any war, irrespective of the origin of the disease, disability or defect necessitating domiciliary or hospital care and irrespective of the financial status of that officer or enlisted man. Furthermore, domiciliary and hospital care including medical treatment, would be furnished to any veteran not dishonorably discharged who is unable to defray the expenses thereof within the limits of the facilities of the Veterans Administration, irrespective of the origin of the disability disease or defect. Any individual who served overseas as a contract surgeon of the army would be entitled

to the benefits proposed by the bill H R 11951, introduced by Representative McGehee Mississippi, proposes to compensate persons disabled by the use of improperly made Jamaica ginger

Government Services

Annual Report of the Navy

The leading cause of death in the U S Navy during 1934 was motor vehicle accidents, according to the annual report of Surgeon General Rossiter. Fifty of the 299 deaths reported were attributed to these accidents, which also headed the list in 1930, 1931 and 1932. In 1933 the leading cause of death was aeronautic accidents. An increase was noted in the general admission rate. 57,271 admissions from all causes gave a rate of 523.58 per thousand persons in the navy. This rate compared with 477.03 per thousand reported in 1933, the lowest rate ever recorded. The increase in 1935 was due chiefly to increases in acute catarrhal fever, acute bronchitis, measles, German measles and bacillary dysentery. From the standpoint of major injuries there were no disasters in 1934. There were 473 cases of influenza reported with no deaths, the admission rate was 432 as compared with 364 in 1933. The admission rate for wounds and injuries was 64.32 per thousand as compared with 63.21 per thousand for 1933. There were 6,995 admissions for accidental injuries and poisonings in 1934 as compared with 6,800 in 1933, 26 per cent of the injuries were sustained by naval personnel when absent from their commands. Forty-eight of the fifty deaths chargeable to motor vehicles were the result of injuries received while on leave or liberty. Athletics and recreative sports were responsible for 1,412 admissions and six deaths. Suicide was responsible for forty-six fatalities and drowning for twenty-eight. There were 377 admissions for mumps during the year. 360 for measles, 1,118 for German measles, and four cases of diphtheria. Acute catarrhal fever was responsible for 10,910 admissions as compared with 6,569 in 1933, giving a total of 51,727 sick days. There were forty-nine admissions for scarlet fever. No case of smallpox was reported. There were 178 admissions for tuberculosis. There were 39,783 sick days reported for all forms of tuberculosis. Seventeen deaths occurred from this cause. Malaria was responsible for 220 original admissions with 6,039 sick days in fifty-nine cases the disease was said to have existed prior to enlistment. A total of 500 admissions was recorded for Vincent's angina, making the admission rate 457 per hundred thousand persons. This is the lowest admission rate since 1924, the first year in which cases were reported under this title. There were eighty-four admissions for dengue, sixty for amebic dysentery and seven for typhoid. Venereal diseases occupied second place among all causes of morbidity and contributed the largest number of sick days of any group. They were responsible for 17.24 per cent of admissions for all causes and 14.46 per cent of the total number of sick days. The admission rate for venereal diseases was 90.28 per thousand, a decrease of 11.88 per cent from the 1933 rate. There were 166,891 sick days reported for this group of diseases. During 1934 there were 1,633 persons invalided from the service. A total of 1,043,481 treatment days in all naval hospitals for all classes of patients was recorded, including 807,829 treatment days of navy personnel, 70,738 of Veterans' Administration patients, and 164,914 treatment days of all other supernumeraries. The total does not include 43,735 treatment days on the hospital ship *Relief*, 2,229 treatment days for tuberculous patients at the naval unit U S Army Fitzsimons General Hospital, Denver and 13,350 treatment days for insane patients at St Elizabeth's Hospital, Washington, D C. For the year ended June 30, 1935, there were 832 members in the medical corps, sixty-two of whom were on duty with the Civilian Conservation Corps. There were twenty-six separations from the service during the year, fourteen by retirement, six by resignation and six by death.

Federal Grants for Health Work Approved

The allocation of \$3,333,000 to the various states from funds authorized under the Social Security Act has been approved for extension of public health work, it is reported. Allocations thus far made include \$225,851.58 for New York, \$78,555.48 for New Jersey, \$37,007.98 for Connecticut and \$179,266.32 for Pennsylvania and cover amounts for the remainder of the current fiscal year. They were determined on the basis of population, special health problems and financial needs.

The Use of Analgesics by Midwives

As more than half the labors in this country are attended by midwives, the problem of a safe and effective method of analgesia has arisen. In a previous letter it was reported that a gynecologist, Mr L C Rivett, had worked out a method of chloroform analgesia by means of 20 minim (1.25 cc) capsules, to be crushed and administered by the midwife or by the patient herself during severe pains. This method has been used in a large number of cases and has been claimed to be quite safe. However, this claim has now been rejected by a committee appointed by the British College of Obstetrics and Gynecology to investigate the question whether there is any safe method of analgesia which can be used by a midwife in the absence of a physician. The investigation was made in hospitals, because there adequate medical supervision and facilities for the necessary observation and recording were available. These were for the most part maternity hospitals or departments attached to medical schools. The records of nearly 10,000 cases of analgesia were studied and classified into three main groups: (1) nitrous oxide and air, (2) chloroform, (3) paraldehyde.

NITROUS OXIDE AND AIR

Nitrous oxide and air were administered by the Minnitt apparatus in 3,238 cases. There were three deaths, which were in no way due to the anesthetic. The conclusion is that the apparatus is safe for midwives in hospitals, provided recent examination by a physician has revealed no contraindication. Its use should be restricted to midwives who are specially trained and who have shown themselves capable. The analgesia is satisfactory in a high proportion of cases. Further experience is necessary before suitability for domiciliary practice is proved.

CHLOROFORM

In 4,975 cases chloroform analgesia was used alone or was supplemented by general anesthesia. There were six deaths. Chloroform is held directly responsible for one of these and to be an important factor in two others, but in no way responsible in the remaining three. The stillbirth rate in the analgesic cases was 2.6 per cent, which is held not to indicate any increased danger to the fetus. The conclusion is reached, "with regret," that chloroform by any method should not be used by midwives acting alone. The immediate and delayed dangers occurred in this investigation. The committee does not consider it possible to guard against such occurrences if the administration is in inexperienced hands.

PARALDEHYDE IN OIL BY RECTUM

Technical difficulties in administration, the need for careful selection of cases and the choice of time for injection, the variable action, and inadequate analgesia at the time of birth, are objections to the use of this method by midwives.

Scholarships for the Victims of Political Persecution

Prof Gilbert Murray states in the *Oxford Mail* that an appeal will shortly be issued for funds to create an institution to act as a successor to the British Academic Assistance Council. One of its functions will be to administer special research fellowships for displaced university teachers. The council was formed three years ago, under the presidency of Lord Rutherford, after the dismissal of 1,000 university teachers in Germany. "Since its advent to power," says Professor Murray, "the Nazi party has dismissed about one sixth of the members of univer-

sity staffs either because they were 'politically unreliable' or were 'non-Aryan'. It is instructive that only about one third of the German scholars whom the Council has assisted have been professing Jews, while one third of the 'non-Aryans' have been baptized Christians. Of the displaced German scholars 700 sought refuge abroad. They included specialists in every academic subject, from Nobel prize winners to young lecturers of only a few years' university experience. By public appeals, to which university teachers in particular have responded generously, the Academic Assistance Council and other academic committees have raised funds for the temporary maintenance of German refugees as research guests in universities. During this period the scholars themselves and the academic committees have discovered throughout the world positions of a more permanent character, which now amount to 382. Thus more than half of the exiles have secured permanent appointments. Though so much has been done, Professor Murray says it would be disastrous if complacency led to any slackening of effort. Some 150 refugee scholars are still not yet established. Though negotiations with South American countries may lead to the appointment of nearly 100 scientists in the near future it is becoming increasingly difficult to find openings. He concludes: "For the next five or ten years a deliberate expansion of the universities by the creation of supernumerary posts, is necessary as an effort to preserve that large section of organized learning which in Germany and elsewhere is threatened with destruction by political intolerance."

The Mystery of a Child Born with a Foreign Body in the Heart

The inquest on the body of a baby that died a few hours after birth has attracted attention in the lay as well as the medical press. A small piece of metal was found in the heart, for which no satisfactory explanation seems to be possible. The reports in the lay press of such an extraordinary occurrence might be dismissed as unreliable, though they are quite circumstantial, but the case is authenticated by a letter to the *Lancet* from the two physicians concerned. They write that they are fully aware of the incredible nature of the case but are impelled to place on record what they believe to be a unique occurrence in the annals of pathology. A female child was born to a primipara, who had an uneventful gestation and a normal labor. The child appeared normal in every way but died suddenly some hours after birth for no apparent reason. A necropsy was performed with meticulous care by one of the physicians in the presence of the other who was assisting and observing closely. The mortuary attendant was also a witness. Nothing was found until the heart was removed and laid on the post-mortem slab. It was dissected with a scalpel and a pair of surgical scissors, which were unplated. When the right ventricle was opened a small bright object was seen lying free within the cavity and was extracted under three pairs of curious eyes. "It was a small piece of metal resembling brass or gilded tin appearing to be a circlet of sorts folded upon itself with regular serrations along the edge and measuring roughly 3 by 2 mm. It looked something like the claw setting of a toy jewel ring, such as is found in Christmas crackers."

The physicians emphasize the fact that there was no possibility of the object having been dropped by one of them as they bent over the heart or of its having been shed by one of the instruments used or of its having been picked up from the post-mortem table. They naturally examined these possibilities and excluded them. They suggest that the foreign body was lying within the uterus at the time of conception and that the growing ovum enfolded it, so that it finally came to be where it was found. When the placental circulation ceased and the child's heart "took over," it caused some momentary effect which produced syncope. They admit that this explanation

seems fantastic and they would welcome alternative suggestions. They do not say anything about contraceptive practices by the mother, which their explanation may suggest or about having the object examined by a skilled metallurgist which its importance seems to require. It might be added that any suggestion that the object was in some way accidentally introduced into the heart post mortem is open to the objection of leaving the sudden death unexplained.

Sputum Cultures for the Diagnosis of Tuberculosis

Petroff, said Professor Bezançon and his co-workers before the Académie de médecine initiated sputum cultures, but this method did not become efficient until the studies of Petragnam and Lowenstein. Sputum cultures are simpler, less expensive and better adapted to the mass diagnosis of tuberculosis than is the inoculation of guinea-pigs. Bezançon followed the Petragnam technique. The medium is mixture of milk, peptone, starch and eggs. The sputum is first homogenized and then centrifugated. The cultures are made from the most purulent part of the sputum, and a special feature of Bezançon's technique is to sew between twelve and twenty-five culture tubes. The number of tubes showing colonies is an indication of the abundance of bacilli in the sputum. Bezançon's statistics include 861 cases, in 743 of which no bacilli could be found either by inoculation or by culture. In 118 the cultures were positive. The importance of sputum culture is emphasized by the fact that in a group of 300 people, apparently healthy and hard workers, six were bacillus carriers and in three the presence of bacilli was found only by culture. Two objections arise: first, these bacilli might be nonpathogenic. Research showed, however, that they were pathogenic and that they were authentic Koch bacilli. Second, these bacilli might come from the upper respiratory tract. Evidence of the pulmonary origin of the bacilli was given by the examination of a large group of nurses of the tuberculosis clinic at the Saint Antoine Hospital, none of whom had a positive culture of the sputum or the saliva. However, the presence of bacilli in sputum is to be interpreted only in connection with other conditions, it is not absolute evidence but should lead to a special and complete examination of the patient.

The Prophylaxis of Measles

Saint Etienne, one of the most crowded towns of France, has more than 200,000 inhabitants, the majority of whom are poor workers with lots of children. Slums and the lack of personal hygiene and sanitation flourish in Saint Etienne. Measles is endemic and the mortality is high. Dr. Poulain, health officer of the town in order to fight this plague sought the collaboration of town officials, the newspapers, the military and civil physicians and the school teachers. Poulain's plan was first to keep babies under 2 years of age away from the disease and secondly to protect the older children against complications. To stop the spread of measles, Poulain discontinued the babies' outdoor service and this was given in the homes. Generally speaking he tried to close every place where babies could be congregated. For the older children who could not easily be kept out of schools and other meeting places, Poulain initiated a systematic use of convalescent serum. Fortunately, the 1934 epidemic started in the garrison so he could have a supply of serum. He was strict in the selection of donors, excluding every one having any fever or a recurrent attack of the measles. Every donor was tested for syphilis and tuberculosis. Even with such limitations he succeeded in obtaining from seventeen donors about 800 cc of serum. Unfortunately, when this stock was

exhausted he was unsuccessful in persuading nonmilitary citizens to give their blood or that of their children. In the last months of the epidemic he was obliged to advise injection of the whole blood of some convalescent relative. Though this method was uncertain, the mortality in 1935 was greatly reduced.

The Third Congress of Comparative Pathology

The third Congress of Comparative Pathology will take place in Athens, Greece, April 15-18. The president is Professor Bennis of Athens and the general secretary is Dr. Codonius of Athens. In the Section of Human Medicine, five subjects will be discussed: (1) echinococcoses, (2) nephroses and amyloses, (3) leishmaniasis, (4) spirochetoses and (5) avitaminoses. In the Section of Plant Pathology the great subject of immunity in plants will provide an important discussion. Judging by the number of essayists, who come from ten different nations, The Societe de pathologie comparee sponsors this congress. The address of the committee of the congress is in Paris, 7 rue Gustave Nadaud.

Death of Professor Fredericq

The death is announced of Professor Fredericq of Liege, who was elected professor emeritus last year. He was 85 years of age and had been professor of physiology in the University of Liege since 1879. He had been a member of the Academie royale de medecine de Bruxelles since 1894. Fredericq combined skill in experimentation with the outlook of a publisher. He was an excellent teacher, whose courses attracted many foreign students. He worked chiefly on the physiology of the heart, the venous circulation and the nervous system. His greatest glory was the *Archives internationales de physiologie* which he founded and which was the most accurate and exhaustive compilation of physiologic material in the world. His son has succeeded him both in his title of professor and as the director of the *Archives*.

The Importance of Geomedical Knowledge

Professor Schuttenhelm, the Munich internist, has developed from data gathered in various parts of Germany an interesting geomedical point of view (*anschauung*). Diseases frequently present differing characteristics even in the locality of first appearance. For example, in Kiel on the Baltic Sea diphtheria is infrequent and mild, whereas from Berlin or Munich extremely severe cases are reported. Scarlet fever is rare at Kiel, and it appears in Geneva, Switzerland, in such a mild form that it is there considered no more dangerous than measles. Infection from *Brucella abortus* is frequently found in Schleswig-Holstein and in Denmark but seldom in Bavaria, although in the latter region the cattle may be infected with *Brucella*. In Kiel, mesenteric tuberculosis is frequent among children, in Basel it is never found. Perhaps differing types of bread and milk ingestion are here of importance. In Geneva tuberculosis takes a more exudative, diffuse and speedier course than in Kiel. More tuberculous meningitis also is encountered.

Remarkable differences exist among diseases of the blood. The disappearance of chlorosis is connected with better hygiene among young girls. On the other hand, increase in the number of cases of thrombosis and leukemia was observed more frequently in northern and eastern Germany than in Bavaria, for example. The same is true of pernicious and essential anemias and hypochromemia. The increase in cases of pernicious anemia after the World War is well known. Pneumonia of the upper lobe is relatively infrequent but of a severe type at Kiel. At Munich it is frequent but relatively mild. One is astonished at the large number of patients presenting circulatory disturbances

at Munich, for example, tricuspid insufficiency with positive hepatic pulsation, a condition rarely encountered at Kiel. Primary sclerosis too is found at Munich. Apoplexy, atherosclerosis and thrombosis are more frequent at Basel than at Kiel. Gastric ulcer and biliary disorders likewise present distinct regional differences. Cirrhosis of the liver shows the strangest distribution of all, alcohol cannot alone be guilty of causing this disease, when in Russia, Hungary and other countries the rate is less than 1 per cent. Psoriasis is frequent in the north. It decreases toward the south and is quite rare in the tropics. Constitutional factors also should be considered, for example, as a cause of prolapses among females. In Vienna this condition results from relaxation of the muscles of the pelvic floor, whereas in Berlin insufficiency of connective tissue of the supporting apparatus is held responsible. Interesting too is the frequently observed decrease from east to west in the birth rate of males. On rare occasions gout is still encountered in England. In Basel it never appears. Obesity is more frequently observed among Lapps and Netherlanders. The significant causative factors are, for the Lapps, excessive ingestion of fat and lack of physical exercise, for the Netherlanders, good nutrition. For diabetes no regional differences are observable. The contrast between the nature of thyroid disturbances at high and low altitudes is well known. Goiter is more prevalent in the highlands; the lowlanders are more subject to thyrotoxicosis and to exophthalmic goiter. Numerous other regional differences in thyroid diseases are found. For example, in Switzerland goiter frequently is accompanied by cretinism, but this is not true for the Netherlands. In Switzerland goiter more frequently is found among the poorer classes than among the rich, in the Netherlands there is no such difference. An endemic goiter of the North German lowland is recognized, a similar condition is found in Norway. The Swiss goiter of puberty often goes into exophthalmic goiter. The thyroid body may thus be influenced by numerous factors of nutrition, climate, living conditions and so on. Regional differences in reactions to iodine are observable. There is perhaps a regional difference in the effect of liver preparations as well. Digitalis must be administered with greater caution at Kiel than at Munich. The part played by racial factors in these differences is as yet unknown to science.

A Revival of Medical History

A reaction has set in against analytic medical research and the elaborate diagnostic and therapeutic methods which during the last decade had come to assume such large proportions. The endeavor has been to master the technic of medical practice through complicated diagnostic and therapeutic methods which stressed the study of separate parts. Now the cry has gone up that the patient should be regarded as an entity. Psychic treatment of the patient by the physician comes more to the fore and greater value is attached to hereditary predispositions and constitutional differences while time honored household remedies of proved worth seek a place beside the products of chemical industry. Although medicine will not cease to be related to the natural sciences, it is henceforth to be considered in conjunction with the age old traditional art of healing which had its origin (1) in the impulse to help and (2) (like all the arts) in the impulse to create. The trend developed in Germany soon after the World War, and there is no doubt that political revolution has given it strength and form. This tendency to go back to the old for enlightenment and to consider science as linked with national political concepts has given a great impetus to research in medical history.

Significant in this connection is the appearance of a fictional biography of Theophrastus Paracelsus. In this three volume novel by Kolbenheyer (the third volume of which is significantly entitled 'The Third Reich'), Paracelsus, formerly considered

primarily a quack and a charlatan, is depicted as a reformer on the grand scale, as the founder of a Germanic school of medicine based on experimentation and intuition. This school broke away from the inflexible tradition of galenic science and from the upper schools (predominantly Italian) of humanistic medicine that existed in former times. Now, more than ever, that earlier popular interest in primitive medicine has been revived. Men outside the regular school are coming in for consideration. Thus Gumpert portrays the life of Hahnemann, the founder of homeopathy. Accounts of historic medical struggles (for example, the unappreciated fight waged by Semmelweis against puerperal fever or the official opposition encountered by Schleich, the inventor of local anesthesia) are revived in publications of all kinds.

As the approximate number of readers of the new literature is not known, it is difficult to determine to what extent the layman may be induced to take an interest in his own body, in contemporary scientific progress and in those questions of hygiene which have become objects of governmental and political concern.

The new literature comes to the physician without entailing any expenditure of money on his part. It serves as propaganda for the chemical and pharmaceutical industry. Formerly the physician's interest and affection were secured by all sorts of little gifts. There came to him unbidden and free of charge thermometers, fountain pens, cigaret cases, pocket scissors and like articles, all discreetly stamped with the name of the manufacturer or dealer. When this type of advertising propaganda was banned by official decree, other sorts of gifts had to be substituted, articles which would bear some relation to the medical profession and be at the same time novel and acceptable. With an accurate comprehension of the zeitgeist, the manufacturers pressed into service the history of medical science, conscious of but blinking the fact that the movement toward the past possessed potential hostility toward modern industrial technique. The periodicals in pamphlet form published by the great pharmaceutical houses (such as Bayer, Schering-Kahlbaum, Normark Werke) and which reproduce accounts in extract form of clinical experimentation with their products virtually all came to carry historical material dealing with ethnologic sojourns into the past, medieval military surgery or the mystic healing customs of antiquity.

CHINA

(From Our Regular Correspondent)

Feb 20, 1936

The Biennial Conference of the Chinese Medical Association

The third biennial conference of the Chinese Medical Association, held in Canton, Nov 18, 1935, was particularly noted for its celebration of the one hundredth anniversary of the Canton Hospital, where Dr Peter Parker first introduced and taught Western medicine in China. This occasion also served as a celebration of the fiftieth anniversary of the beginning of Dr Sun Yat sen's medical and revolutionary work. The first event was further celebrated by the opening and dedication of the new Canton Hospital, which is the direct continuation of the work which Parker began a century ago. The latter event was likewise celebrated by laying the corner stone of the new Sun Yat sen Medical School. This occasion was honored by the special visit from the United States of the grandson of Dr Peter Parker. More than 400 physicians from all parts of China were present at the conference, including the extreme northwest and 220 scientific papers were presented.

On the special centenary program a paper on "The Future of Medicine in China" was read by Dr F C Yen, director of the National Medical College of Shanghai. He dealt vigorously with the proposal of the government to lower medical education standards in order to secure quickly a large number

of doctors. "If more schools are started and staffed with unqualified teachers, it is bound to flood the profession with a large number of practitioners of quackery and commercialized medicine. In this way the standards of medical practice may not be upheld and it is doubtful whether in the end this will hasten the real progress of scientific medicine in China. The experience of other countries has shown that it is more difficult to fight against quackery and commercialized medicine when poorly trained doctors have once been admitted into the medical profession as recognized practitioners. Our government is determined to carry out a national medical program designed to provide medical care for all.

For this reason the national health administration has issued the following statement as its national policy. State medicine is the only policy to effect medical protection for the mass of the population in an efficient manner and the objective of community protection through state medicine necessitates an organized system of medical and public health services. For a unit of 5,000-10,000 of population there should be a rural health substation to take care of simple medical and health work, and for every five or ten such substations there should be a district health station to render more fundamental health and medical service to the people. In a county there should be a health center, which includes a hospital, a simple laboratory and an administrative organ for the supervision of medical and public health work under its jurisdiction. Similarly, a provincial health center should be built on a larger scale to supervise and assist the different county administrations. Above all these local organizations there should be a national health organization to organize and supervise the medical and health work throughout the country. Under such a system it would eventually be possible to bring health protection to every individual of the population in the most logical and effective manner. To carry out efficiently this national policy all available medical and public health institutions and services should be fully utilized and guided along the lines of the general policy mentioned. It has been felt by those who are interested in social reconstruction work that during the past ten years too many individual efforts for the different classes of social reconstruction have been carried out without regard to coordination. In the medical field one cannot afford such lack of coordination. The declared policy of our government in favor of state medicine will undoubtedly hasten the time of government provision of medical care to the people. Then there will be an inevitable demand on medical schools for the training of personnel competent to practice state medicine, with the result that the medical school must adjust its curriculum and training methods so that they may be equal to the new responsibilities placed on them.

COUNCIL ON CONTRACEPTION

The conference passed the following resolution, proposed by Dr Amos Wong: "That the Chinese medical profession recognize that contraception is a part of the activities of public health, especially in the field of maternity and child welfare." In pursuance of this resolution a special council was appointed to deal with the question of birth control in China. Since the closing of the conference the council has met organized and laid down a program of procedure. In Shanghai a birth control league has been organized and Mrs Margaret Sanger, pioneer in this field, is to visit Shanghai in March.

New National Medical College of Shanghai

The National Medical College of Shanghai is the first government school to undertake seriously the establishment of a school of what is known in the United States as grade A. Under the leadership of Dr F C Yen, a graduate of Yale in 1909, this school was begun in a simple way in 1927. Dr Yen is a direct descendant of China's greatest sage, Con-

fucius He is of the seventy-fifth generation Dr Yen had some valuable experience in the Hunan-Yale school, where he developed qualities of leadership which have enabled him to direct his institution successfully to the establishment at present of what will soon be the greatest medical center in all China To this undertaking the Rockefeller Foundation donated a tract of more than 20 acres of land in the French concession close to the old walled city of Shanghai This valuable land and location have been held for a good many years for this purpose When it came to construction activities the authorities controlling the French concession refused to permit the institution to be built on this site, supposedly because of the proximity of a small medical school under French control This opposition caused a delay of more than a year in securing another suitable location

Construction has now begun on a site that is fully under Chinese control and still convenient to the center of population Nearly 20 acres in a city of four million population is a lot of land to devote to one institution But this undertaking promises to be the greatest medical center in China and it will ultimately have more buildings than are now being constructed and is going to have to assume the health responsibility for a very large population The present construction program consists of 1 A dispensary building designed to take care of 500 patients daily This is a three story building located at the corner of the approach It is thus convenient to the public and directly connected to the hospital behind 2 The hospital building of 500 beds This is five stories high and has many attractive features both in construction and in arrangement It is designed especially for teaching purposes and will accommodate all the services of the school Adequate space is reserved for extending this building to accommodate a thousand beds 3 A nurses' building to accommodate 150 pupil nurses and fifty graduate nurses with adequate facilities for demonstration, class, reading, social and dining rooms 4 The medical school building, designed for the present accommodation of 300 students There will be ten fully equipped laboratories for chemistry, physics, biology, anatomy, physiology, pathology, bacteriology, biochemistry, pharmacology and public health Each of these will have its own offices, lecture halls, rooms for teaching, and research laboratories Administration offices, the library and the museum will be included in this building It consists of two wings of three stories and the central block of four stories 5 A student dormitory for the accommodation of 300 All these buildings are to be of modern construction in the beautiful lines of Chinese architecture The most striking feature will be the roof, with its gentle curves and green glazed tile The walls will be of red brick They will be ready for occupancy by fall

While the National Medical College is a government institution, it has been put under the control of a self-perpetuating board of directors, the chairman of which is Dr H H Kung, minister of finance in the Chinese government at Nanking Dr Kung is a direct descendant of Confucius in the seventy-second generation He is a graduate of Oberlin College in Ohio and has been active in public affairs in China

In addition to this hospital now under construction, the National Medical College has under its control or available for its teaching purposes the following institutions 1 The Chong Chung Memorial Hospital for Tuberculosis, also known as the Kungwan Tuberculosis Sanatorium It has been reconstructed from a magnificent private garden donated by a wealthy Chinese merchant It accommodates 120 patients This is owned by the college itself 2 The Hungjue Sanatorium 3 The extensive public health work of the municipality of Greater Shanghai This includes both city and suburban or country work, where modern rural work is now being directed 4 The Shanghai Nerev Hospital, a new and model psychopathic institution,

which was recently opened in Shanghai 5 The National Leprosarium, just completed at Dahzang near Shanghai This has been built as a model institution and is hoped to stimulate the improvement of leprosy institutions all over China 6 The Chinese Infectious Disease Hospital

Narcotic Control by the Government

The Chinese government has formed new regulations for the importation of the following ten narcotics opium, morphine hydrochloride, codeine, ethylmorphine hydrochloride, apomorphine hydrochloride, cocaine hydrochloride, strychnine hydrochloride, pantopium hydrochloricum, fluidextract of cannabis indica, and acetone codeine The regulations make it impossible for any of these drugs to be imported except by the government itself, which will in turn distribute them to hospitals and practitioners through one organization, the Central Hygienic Laboratory This move is only one of the firm and vigorous attempts on the part of the government to control opium and other habit forming drugs Government officials are requiring payment in advance and selling only to qualified registered physicians

New Sources of Vitamin A and Their Uses

Dr Peter G Mar read a paper January 22 before the Henry Lester Institute of Medical Research in Shanghai He reviewed the present general knowledge of vitamin A and pointed out that night blindness is a well defined condition described in old Chinese medicine and indicates that it has a nutritional basis Since vitamin A speedily cures this condition he undertook an investigation of old Chinese remedies recommended, with interesting results regarding their vitamin A content and carotenoid values Some of the 146 remedies so studied had low values, while feces of the flying fox, bat and sparrow, which are still much used in China, yielded very high results In this list were twenty-two inorganic remedies, which yielded various results Sixty-five vegetable substances were examined, twenty of which were found to have a higher value, eight an equal value, and thirty-seven a lower value than cod liver oil Atractylis gave values about eighteen times that of cod liver oil Coltsfoot, broom, pink, yam and ink plant all had high values He discussed further the use of these remedies in connection with vesical calculus, leprosy and generally recognized vitamin A deficiency diseases It is possible that in the old Chinese medicine these remedies gained their favor because of their vitamin A and provitamin A potency

Marriages

JAMES I BIAKILY to Mrs Helen Vernon Fawley, both of Fairfield, Ill, in Paducah, Ky, January 19

JOSIEP EVANS BRUNSON, Taylors, S C, to Miss Betty Cauble Gibson of Greenville, February 9

WALTER AUSTIN BACON, Pottsville, Pa, to Miss Elizabeth Flock of Williamsport, February 8

OTIS R PLATT North Platte, Neb, to Miss Mary K McHugh of Murdock, recently

CHARLES M MCGILL, Seattle, to Miss Edith Hanson of Forest Grove Ore, recently

WILLIAM M COVONI, Chicago, to Miss Eleanor Lindquist of Webster, Wis, February 20

JACOB N BAILLY to Miss Thelma Elizabeth Drinnon, both of Paducah Ky, February 6

ANTHONY P DESTI, Brooklyn, to Miss Frances Licata of Tampa, Fla, January 4

HAROLD M BLOCK, Dallas, Texas, to Miss Jane Landau of New York, January 3

HERBERT M COIFMAN to Miss Grace Perdue, both of Fredericksburg, Va January 26

Deaths

Malcolm LaSalle Harris ☉ President of the American Medical Association 1928-1929, died at the Milwaukee Sanitarium, Wauwatosa, March 22, after an illness of more than a year. Dr Harris was born June 27 1862, in Rock Island County Ill the son of Samuel G and Frances Green Harris. His early education was received in the public schools of Iowa and his medical education at Rush Medical College from which he received the degree of doctor of medicine in 1882. Since he was only 20 years of age at the time, he was required to wait one year before taking the examination for licensure. He practiced medicine continuously in Chicago after his graduation, teaching also in the Cook County Hospital and serving as professor of surgery in the Chicago Polyclinic. Following reorganization of the American Medical Association in 1901, Dr Harris became a member of the House of Delegates and was in attendance at all sessions either as a member of the House, of the Board of Trustees or of the Judicial Council from 1901 through 1934. He was a member of the Board of Trustees from 1903 to 1918, most of the time acting as secretary of the Board. He was a member of the Judicial Council from 1918 through 1928 serving also as its chairman. He had been president of the Chicago Medical, Chicago Surgical and Chicago Pathological societies and also of the Western Surgical Association. He was also a member of the International Surgical Association, the American Surgical Association and the American Association for Clinical Surgery. In the Section on Surgery of the American Medical Association he was secretary in 1898 and 1899. His contributions to medical literature included not only the translation and editing of Braun's "Local Anesthesia" but also contributions to the Oxford, Keen's and Bryant's Systems of Surgery. More recently he had written significant essays in the fields of medical economics and statesmanship. He served continuously as secretary of the board of trustees of Henrotin Hospital from 1889 until retired as president emeritus in 1935. The passing of Dr Harris is mourned by a wide circle of distinguished political industrial and medical leaders. He was a clear and profound thinker, shrewd in his estimation of men and of their motives and characterized as the possessor of a mind both scientific and legal. Diffident and cautious in his intimacies, his friendship was greatly esteemed and highly appreciated by all who knew him well.

MALCOLM LASALLE HARRIS M D, 1862-1936

Allard Memminger, Charleston, S C, Medical College of the State of South Carolina, Charleston, 1880, member of the South Carolina Medical Association formerly dean and professor of chemistry and hygiene and clinical urinary diagnosis at his alma mater, and professor of general and applied chemistry at the College of Pharmacy of South Carolina at one time member of the State Board of Pharmacy Examiners of South Carolina and chairman of the city board of health, a contributor to medical and literary magazines, aged 81 died January 16, of influenza and bronchopneumonia.

Harris Ellett Santee ☉ Chicago University of Pennsylvania Department of Medicine Philadelphia 1892, member of the American Association of Anatomists, professor of anatomy, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1900-1910 professor of nervous anatomy, Chicago College of Medicine and Surgery 1910-1917, author of 'Anatomy of Brain and Spinal Cord' aged 71 died February 28 in the West Side Hospital of chronic bronchitis and myocarditis.

Hugh Prescott Ross, Nampa Idaho Trinity Medical College Toronto Ont, Canada 1900, member and past president of the Idaho State Medical Association past president and

secretary of the Canyon County Medical Society at one time member of the state legislature, member of the state board of medical examiners on the staff of the Mercy Hospital, aged 60, died, January 17 of pneumonia.

William S Tomlin ☉ Indianapolis, University of Louisville (Ky) Medical Department 1892, member of the American Academy of Ophthalmology and Oto-Laryngology fellow of the American College of Surgeons, on the staffs of St Vincent's Methodist Episcopal St Francis, and Indianapolis City hospitals aged 67, died January 27, of cardiovascular renal disease.

Herrman Hirsch Harris ☉ Jacksonville Fla Tulane University of Louisiana Medical Department, New Orleans, 1910 past president of the Duval County Medical Society, served during the World War aged 52, on the staffs of the Duval County Hospital St Luke's Hospital and St Vincent's Hospital, where he died January 20 of coronary thrombosis and arteriosclerosis.

Ira Leckrone, Silver Lake Ind, Rush Medical College, Chicago 1896 member of the Indiana State Medical Association elected president of the Kosciusko County Medical Society at the December meeting, aged 66, died, January 15, in the Woodlawn Hospital Rochester, of injuries received when the automobile in which he was driving was struck by a train.

Charles Mills Gleason ☉ Manitowoc, Wis, Rush Medical College, Chicago, 1901, past president of the Manitowoc County Medical Society, and councilor of the fifth district of the State Medical Society of Wisconsin, aged 66 on the staff of the Holy Family Hospital, where he died, January 19, of coronary embolism.

John Harris Vance, Omaha, Jefferson Medical College of Philadelphia, 1886 past president of the Omaha-Douglas County Medical Society, at one time member of the school board, formerly on the staff of the Wise Memorial Hospital, aged 77 died, January 16, in the Immanuel Hospital, of pneumonia.

Linwood Melrose Keene, Crownpoint, N M Medical School of Maine, Portland, 1904, served during the World War, on the staff of the Eastern Navajo Agency Hospital, aged 61, died, January 14, in the Veterans Administration Facility, Albuquerque, of streptococcal sore throat.

Omer Davis Hutto ☉ Kokomo, Ind, Indiana Medical College, School of Medicine of Purdue University, Indianapolis, 1906 past president of the Howard County Medical Society, on the staff of the Good Samaritan Hospital, aged 56 died, January 26 of coronary occlusion.

James A Rosoff ☉ Compton Calif, Northwestern University Medical School, Chicago, 1924, instructor in medicine, University of Southern California Medical School, Los Angeles, since 1934 on the staff of the Los Angeles County Hospital, aged 36 died January 24 in the Hospital of the Good Samaritan Los Angeles of uremia.

Francis S Feeney ☉ New Hampton, Iowa, College of Physicians and Surgeons of Chicago School of Medicine of the University of Illinois 1898 formerly county coroner, on the staff of St Joseph's Hospital, aged 61 died, January 18, of coronary occlusion.

James Alexander Irwin, Philadelphia, Jefferson Medical College of Philadelphia 1891 member of the Medical Society of the State of Pennsylvania, for many years on the staff of the Jefferson Hospital aged 84 died, January 6, of carcinoma of the prostate.

Alexander Irvine, McDowell W Va, Medical College of Virginia Richmond, 1887 formerly superintendent of the Welch (W Va) Hospital number 1, now known as the Welch Emergency Hospital, aged 73, died suddenly, January 14 of angina pectoris.

Gustave Adolphus Wedemeyer ☉ Taylor, Texas, Tulane University of Louisiana Medical Department, New Orleans, 1899, past president of the Williamson County Medical Society, aged 61, died, January 24, in Temple, of mastoiditis and diabetes mellitus

Harry Eastman Hitchcock, Woodbridge, Conn., Medical School of Maine, Portland 1898, served in the U S Public Health Service during the World War formerly district health officer for the west coast of Florida, aged 63, died, January 6

George Oscar Hulick ☉ East St Louis Ill American Medical College, St Louis, 1902, formerly professor of obstetrics at his alma mater past president of St Clair County Medical Society, aged 59, died, February 3, of myocarditis

William Nassau Kendrick, Spring Valley, Minn McGill University Faculty of Medicine, Montreal Que, Canada, 1896 member of the Minnesota State Medical Association, aged 63, died, January 21, in Rochester of agranulocytic angina

William James Hawkins, San Francisco, University of California Medical Department, San Francisco, 1890 fellow of the American College of Surgeons, for many years on the staff of the French Hospital aged 66 died, January 7

John G Kinneman ☉ Goodland Ind Medical College of Indiana, Indianapolis, 1898, formerly secretary of the Jasper-Newton Counties Medical Society aged 67 died, January 23 of coronary occlusion and valvular heart disease

Winston Garfield Ramey, Protection Kan University of Louisville (Ky) Medical Department 1907 member of the Kansas Medical Society, served during the World War aged 54, died, January 6, of meningioma of the brain

William Alexander Gowan, Kosciusko, Miss College of Physicians and Surgeons Memphis Tenn 1909 member of the Mississippi State Medical Association aged 56, died January 14 in a hospital at Jackson, of pneumonia

Charles Kline Ferer ☉ Meadville, Pa Medico-Chirurgical College of Philadelphia, 1904 served during the World War on the courtesy staff of the Meadville City Hospital, aged 55, died January 15 of coronary occlusion

William B Richardson ☉ Parkersburg, W Va College of Physicians and Surgeons Baltimore 1914 served during the World War, on the staff of St Josephs Hospital, aged 45, died, January 1, of coronary occlusion

George Hatch Beebe, Pittsfield Mass Albany (N Y) Medical College 1894, aged 68, for many years on the staff of St Luke's Hospital where he died, January 15, of cerebral hemorrhage and bronchopneumonia

Edward Donald Sorteberg, Cannon Falls, Minn University of Minnesota Medical School, Minneapolis 1932, aged 28, died, January 17, in the Fitzsimons General Hospital, Denver, of pulmonary tuberculosis

Knud Hanson ☉ Grand Junction, Colo Denver College of Medicine, 1898, fellow of the American College of Surgeons attending surgeon to St Mary's Hospital, aged 61 died Dec 25, 1935, of bronchopneumonia

James M Nealon ☉ Plymouth Pa College of Physicians and Surgeons Baltimore 1902, aged 59, on the staff of the Mercy Hospital, Wilkes-Barre, where he died, January 9 of diverticulitis and peritonitis

John William Clark, Oak Hill, Ohio, Ohio Medical University Columbus, 1893, served during the World War formerly county health officer, aged 68 died, January 3, of ventricular fibrillation

Jessie Drew Carpenter, Manitowoc, Wis College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1903, aged 72, died, January 20, of aortic regurgitation

Thomas Leo Brennan, New York, University and Bellevue Hospital Medical College New York, 1926, at various times resident in the tuberculosis service at Bellevue Hospital, aged 38, died January 8

Charles Andrew Trumbauer, Denver Keokuk (Iowa) Medical College 1897 member of the Colorado State Medical Society aged 65, died, February 4, in the Presbyterian Hospital of uremia

Charles Wickham Parker, Chicago, Eclectic Medical College of the City of New York 1882 Rush Medical College, Chicago 1893 aged 81, died, Dec 30, 1935, of carcinoma of the rectum

Henry T Dickens, Wilsonville Ala Georgia College of Eclectic Medicine and Surgery, Atlanta 1889, member of the Medical Association of the State of Alabama aged 71, died, January 8

John Woodbridge Bosworth, Philippi, W Va (licensed in West Virginia in 1881), member of the West Virginia State Medical Association, Civil War veteran, aged 97, died, January 4

Seth Jones Montague, Durham, N C, Bellevue Hospital Medical College, New York, 1872, aged 85 died, January 28, in the Watts Hospital, Durham, of carcinoma of the pancreas

Alburn Matthias Stafford, San Diego, Calif, University of the City of New York Medical Department, 1888, aged 70, died, January 19, of cerebral hemorrhage and angina pectoris

Henry W Drury, Mineral Wells, Texas (registered by Texas State Board of Medical Examiners, under the Act of 1907), aged 67, died, Dec 5, 1935, of cerebral hemorrhage

Hardy David Havard, Theodore, Ala, University of Alabama School of Medicine, 1911, served during the World War, aged 46, died, January 15, of carcinoma of the esophagus

William Arthur Method, Columbus Ohio, Ohio Medical University, Columbus, 1906, member of the Ohio State Medical Association, aged 55, died, January 16, of pneumonia

Charles North Mason, Newport, N C, College of Physicians and Surgeons, Baltimore, 1882, aged 81, died, January 18, of cerebral hemorrhage and diabetes mellitus

Stephen Kerr Patten, Boston, Harvard University Medical School, Boston, 1897, aged 65, died, January 11, in the Peter Bent Brigham Hospital, of cerebral hemorrhage

A Pierce Kemp, Macon, Ga, Southern Medical College, Atlanta, 1889, member of the Medical Association of Georgia, aged 67, died, January 13, of lobar pneumonia

Samuel H Slote, Brooklyn, Baltimore Medical College, 1893, member of the Medical and Chirurgical Faculty of Maryland, aged 75 died, January 16, of pneumonia

William Frederick Woller, Oakland, Calif, College of Physicians and Surgeons of San Francisco, 1914, aged 50, died, January 9, of endocarditis and nephritis

Daniel James Hoyt, New York, University of Vermont College of Medicine Burlington, 1902, aged 63, died, January 8, of coronary thrombosis and arteriosclerosis

Robert Cleveland Williams, Wallace, N C University of Maryland School of Medicine, Baltimore, 1912, aged 49, died January 27, of coronary thrombosis

David Nathaniel Dabbs, Rocky Comfort Mo University of Tennessee Medical Department, Nashville, 1890 aged 74, died January 18 of cerebral hemorrhage

Millard F Powell, Little Rock, Ark, Arkansas Industrial University Medical Department, Little Rock, 1892, aged 75, died, January 10, in Pensacola, Fla

Joseph A Tate, Ennis, Texas, University of Tennessee Medical Department Nashville, 1888, aged 73, died January 14 of pneumonia and heart disease

Jacob Wendell Clark ☉ Chicago, Rush Medical College, Chicago, 1899, served during the World War, aged 57, died, January 30 of coronary thrombosis

Charles Theodore Doremus, San Antonio, Texas, Memphis (Tenn) Hospital Medical College, 1891, aged 74, died, January 14, of chronic myocarditis

Gilbert Milton Bargar, Blaine, Ohio, Starling Medical College, Columbus, 1892, aged 65, died, January 4, of hemiplegia and cardiovascular disease

Franklin Bache Van Nuys, Jackson, Mich Medical College of Indiana, Indianapolis, 1889, aged 70, died, January 18, of cerebral hemorrhage

Augustus C Boyles, Mount Airy, N C Baltimore University School of Medicine, 1897, aged 68, died, January 28, of myocarditis

Claude Owen Reist, Preston, Ont, Canada Queens University Faculty of Medicine, Kingston, 1919, aged 40, died, January 29

John D Leeson, Aylmer (West), Ont, Canada, University of Toronto Faculty of Medicine, 1903, aged 60 died January 29,

John Alexander Lawson, Brampton, Ont Canada University of Toronto Faculty of Medicine, 1894 died, January 17

George W Tucker, Franklin Ind (licensed in Indiana in 1897) aged 91, died, January 26, of arteriosclerosis

Arthur De Voe, Seattle, University of Buffalo School of Medicine, 1875, aged 85 died, Dec 29, 1935

Eli Taylor, Nezperce Idaho, Louisville (Ky) Medical College, 1895 aged 83, died, Dec 15, 1935

Bureau of Investigation

MISBRANDED "PATENT MEDICINES"

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States Department of Agriculture

[EDITORIAL NOTE The abstracts that follow are given in the briefest possible form (1) the name of the product, (2) the name of the manufacturer, shipper or consigner, (3) the composition, (4) the type of nostrum, (5) the reason for the charge of misbranding and (6) the date of issuance of the Notice of Judgment—which may be considerably later than the date of the seizure of the product]

Ammon's Gall Stone Remedy and Ammon's Oil Gall Stone Remedy—Home Remedy Co Pittsburgh Composition Gall Stone Remedy Essentially plant drug extracts including podophyllum alcohol (8.6 per cent by volume) and water small envelope of epsom salt accompanied it Oil Gall Stone Remedy Essentially in oil having the odor of olive oil and plant drug extracts including podophyllum Fraudulent therapeutic claims—[N J 23235 May 1935]

Ammon's Get Well Eat Well Stay Young—Home Remedy Co Pittsburgh Composition Essentially plant drug extracts alcohol (about 9 per cent) and water Cure all Misbranded because alcohol content was wrongly stated and because of fraudulent therapeutic claims—[N J 23235 May 1935]

Chlorine Respirine—Chlorine Respirine Co Chicago and Indianapolis Composition Essentially a calcium compound chlorides and a trace of chlorine in petrolatum For bronchitis laryngitis influenza etc Fraudulent therapeutic claim—[N J 23025 April 1935]

Hill's Nose Drops—Wyeth Chemical Co Detroit Composition Essentially ephedrine (0.5 per cent) and essential oils including peppermint and wintergreen (5 per cent) incorporated in mineral oil For catarrh hoarseness rhinitis etc Fraudulent therapeutic claims—[N J 23248 May 1935]

Adgene—Adgene Inc Paterson N J Composition Essentially barley malt sugar cocoa and calcium and phosphorus compounds For underweight run down conditions etc Fraudulent therapeutic claims—[N J 23254 May 1935]

Trunk's Prescription—Trunk Bros Drug Co Denver Composition Essentially potassium iodide extracts of plant drugs including colchicum and a laxative with alcohol and water For rheumatism skin and blood disorders etc Fraudulent therapeutic claims—[N J 23255 May 1935]

Chesto—Muir Laboratories Grand Rapids Mich Composition Chiefly petrolatum and small amounts of volatile oils including eucalyptol menthol oil of pine and camphor For coughs asthma catarrh hay fever boils piles etc Fraudulent therapeutic claims—[N J 23257 May 1935]

Lightning Lax Pills—Muir Laboratories Grand Rapids Mich Composition Essentially plant drugs including a laxative For biliousness pimples debility bad blood etc Fraudulent therapeutic claims—[N J 23257 May 1935]

Vegetate—Health Foundation of California Los Angeles Composition Essentially calcium carbonate and powdered plant material including rice kelp alfalfa and senna in tablet form For hyperacidity bloating constipation, etc Fraudulent therapeutic claims—[N J 23260 May 1935]

Fullerine—Fuller Hill Corp Chicago Composition Essentially alcohol (27 per cent) boric acid (1.6 per cent) and small amounts of benzoic acid and volatile oils including thymol and menthol For dan druff sore throat aching feet etc Not antiseptic Fraudulent therapeutic claims—[N J 23261 May 1935]

Lambert's Rheumatic Powders—Lambert Chemical Corp Minneapolis Composition Essentially acetanilid (2.3 grains per tablet) aspirin and salol Misbranded because of false statement on label that it contained nothing injurious and because of fraudulent therapeutic claims—[N J 23262 May 1935]

Wonderful Dream Salve—Wonderful Dream Salve Co Detroit Composition Essentially creosote in an ointment base For abscesses boils carbuncles sore eyes corns etc Fraudulent therapeutic claims—[N J 23263 May 1935]

W D S Pills—Wonderful Dream Salve Co Detroit Composition Essentially plant material including aloë For blood and liver disorders rheumatism etc Fraudulent therapeutic claims—[N J 23263 May 1935]

Arko Eczema Salve—Arko Herbs Inc Composition Essentially zinc oxide (11.2 per cent) and tar in a petrolatum base Fraudulent therapeutic claims—[N J 23272 May 1935]

Booth's Hyamel—Booth's Hyamel Co Ithaca N Y Composition Volatile oils (32 per cent) including eucalyptol and menthol with creosote alcohol and water For catarrh croup laryngitis etc Not antiseptic Fraudulent therapeutic claims—[N J 23266 May 1935]

Kremola Skin Bleach—Kremola Co Dr C H Berry Co Chicago Composition Essentially ammoniated mercury (6.35 per cent) and zinc stearate (13.5 per cent) in petrolatum perfumed For eczema pimples acne etc Fraudulent therapeutic claims—[N J 23268 May 1935]

Stoll's Diet Aid—Diet Aid Sales Co Chicago Composition Essentially corn starch sugar cacao powder and caramel For obesity (food substitute) Fraudulent therapeutic claims—[N J 23271 May 1935]

Diana Soshorszesz—Diana Mfg Co Masontown and Uniontown Pa Composition (Large bottle) Essentially alcohol (39.7 per cent) acetone ethyl acetate volatile oils including peppermint oil (7.8 per cent) boric acid zinc phenolsulphonate and water (small bottle) essentially alcohol (48.8 per cent) acetone ethyl acetate volatile oils including peppermint oil (1.2 per cent) acetic acid common salt and water For rheumatism lumbago, gout etc Fraudulent therapeutic claims—[N J 23269 May 1935]

GLYCOSURIA FROM TREATMENT WITH ANTERIOR PITUITARY-LIKE HORMONE FOR IMPERFECTLY DEVELOPED TESTIS

To the Editor—In a recent article by Dr Harry Koplin on glycosuria caused by administration of antuitrin-S for bilateral undescended testes (THE JOURNAL, February 1, p 374) it was stated by the author that after injections of antuitrin-S (twenty-four 1 cc injections in eight weeks) for undescended testes in a child, aged 30 months polydipsia, polyuria, enuresis and glycosuria were produced Three weeks after the cessation of treatment with antuitrin-S, these symptoms and the glycosuria disappeared

The occurrence of the aforementioned symptoms stimulated a more careful review and recheck of a number of patients in my series who were treated or are being treated for maldeveloped or maldescended testes with the gonadotropic hormone of the urine of pregnant women (Follutein-Squibb)

In none of the cases previously reported by me in the literature (Maldevelopment and Maldescent of the Testes, *Am J Dis Child* 50 649 [Sept.], 1429 [Dec.] 1935) or in those not reported (sixty patients in all, the majority ranging in age from $3\frac{1}{3}$ to 15 years, the rest being adults or in late adolescence) was there any suspicion of glycosuria, as might have been evidenced by the symptoms of polydipsia, polyuria or enuresis

This suspicion was lacking because of this absence, in all patients, of the subjective complaints in question and because of the definite absence of dextrose in the urine specimens of those several patients who were studied Not all of these cases, therefore, were subjected to intensive urine studies before this time Nevertheless, after Koplin's report I instituted a check up

Antepandrial and postprandial urine specimens of one group of sixteen patients, ranging in age from $5\frac{1}{2}$ years to 14 years with one patient 19 years of age, who are at present showing good genital response to the anterior pituitary-like gonadotropic principle from the urine of pregnant women (with the exception of 2 patients—the 19 year old boy, and a 6 year old boy who has received an insufficient amount of the anterior pituitary-like principle derived from an extract of the placenta), were taken and examined a number of times for each patient These were tested for dextrose by the Benedict qualitative method The urines of these sixteen patients (even in the one in whom a different brand of gonadotropic principle was used) showed an absence of dextrose

In addition to this study of the urine of the patients still under treatment, I examined several specimens of urine from eight boys who had received and completed a course of treatment with this hormone and who had therefore already been

discharged after showing a satisfactory genital response. This group was all under 14 years of age. The lapse of time between the last injection of this hormone and the institution of this urine study ranged from four to twenty months. There was no evidence of glycosuria in any of the patients of this group.

I feel, therefore, that the glycosuria in the patient observed by Koplin might have been a coincidental finding or one peculiar to this patient, for it can be stated with certainty that neither my patients who are at present receiving treatment or the eight patients of the group who had received and completed treatment with gonadotropic substance of the urine of pregnant women for their imperfectly developed testes showed polydipsia, polyuria, enuresis or glycosuria.

It must not be overlooked that the commercial preparation used by Koplin differed from the one that I used. However, I have had the occasion to check on the product antuitrin-S used by Koplin, in three of my patients who have received by now, large quantities of this hormone. I have found no glycosuria present.

SENSITIZATION OF GUINEA-PIGS WITH METHYL HEPTINE CARBONATE

To the Editor—Prompted by a recent editorial comment (*Lip Stick Dermatitis*, *THE JOURNAL* February 8 p. 470) we report briefly experiments which have shown that sensitization of animals with methyl heptine carbonate can be effected by methods used in previous work on dinitrochlorobenzene and other substances (Landsteiner, Karl, and Jacobs, John, *Studies on the Sensitization of Animals with Simple Chemical Compounds*, *J. Exper. Med.* 61: 643 [May] 1935). The investigation was made on account of observations in human beings on dermatitis due to facial cream or lip stick containing methyl heptine carbonate and "perfume dermatitis" described in papers first brought to our attention by Dr. Simon Fleisher (Hoffman, M. J., and Peters, John, *Dermatitis, Due to Facial Cream Caused by Methyl Heptine Carbonate*, *THE JOURNAL* March 30, 1935, p. 1072; Baer, H. L., *Perfume Dermatitis*, *ibid.* May 25, 1935, p. 1926).

Ten intracutaneous injections at weekly intervals in white guinea-pigs on the back, of 0.05 cc of olive oil containing 0.5 mg of methyl heptine carbonate were followed by two weeks of rest and the animals tested by gently spreading one drop of a 20 per cent alcoholic solution of the substance on the skin of the flank. While normal animals, as a rule, do not show any reactions, in a considerable number of the sensitized pigs the treated sites became pink, sometimes elevated and the sensitization was specific as demonstrated in cross tests with animals sensitized with 2,4-dinitrobenzyl chloride or chlorobenzyl chloride, 2,4-dinitrochlorobenzene, urushiol and *p*-nitrobenzyl chloride.

In several animals, sensitization could be produced by applying methyl heptine carbonate to the surface of the skin.

In keeping with the suggestion mentioned in our report, one may suppose that in this case also the capacity of methyl heptine carbonate $\text{CH}_3(\text{CH}_2)_7\text{C}=\text{CO}\text{CH}_3$ to sensitize is due to its chemical reactivity, particularly the ability to combine with basic groups (Moreu and Lazennec, *Compt. rend. Acad. d. sc.* 143: 596, 1906) so that it would seem probable that the substance may be converted into antigenic compounds in the animal body.

KARL LANDSTEINER, M.D.

SPUTUM EXAMINATION IN TUBERCULOSIS

To the Editor—I should like some information about sputum examination in tuberculosis or in suspected cases especially in children. One man's opinion is that sputum examination is no good for early cases since by the time bacilli can be found in the sputum the disease is well advanced and other signs are numerous. Another opinion is that the bacilli are found in early cases in the sputum before any other signs are demonstrable. What is the latest thought on this question? What is the best way to collect a specimen? Is the sputum of an extremity of the day better?

ARTHUR B. DAVENPORT, M.D., Tunkhannock, Pa.

ANSWER—Examination of the sputum should be made in all cases of tuberculosis or even of persons suspected of having the disease. Frequently the patient states that he does not have any sputum. In such cases it is worth while to collect for examination the material that he believes is only cleared from his throat. In the case of infants and children one is usually dealing with the primary form of tuberculosis and there is usually no sputum expectorated. However, when the disease is in the acute pneumonic stage and occasionally even after calcium has been deposited, tubercle bacilli may be recovered from the gastric contents or the feces. Since the infant does not expectorate, a common method of attempting to obtain sputum is by the use of a cotton swab to collect the sputum from the throat while the infant gags. However, this method is not always satisfactory.

The most accurate method of demonstrating tubercle bacilli in the bodies of infants is as follows: After the infant has been without food for six hours, from 200 to 300 cc of sterile water is used to wash the stomach. This water is then centrifuged and the sediment stained for tubercle bacilli. If the microorganisms are not found, some of the sediment is planted on one of the mediums such as that of Corper, Sweany or Petroff, and some is inoculated into the bodies of guinea pigs. By culture and inoculation methods, demonstration of tubercle bacilli is often possible when the microscopic examination of the sediment alone fails to reveal them. Such workers as Poulsen, Jensen and Husted (*Am. J. Dis. Child.* 37: 900 [May] 1929), Willis (*Tr. Nat. Tuberc. A.* 1933 p. 135) and Gourley (*Am. Rev. Tuberc.* 29: 461 [April] 1934) have made rather extensive studies on this subject.

Apparently, the tubercle bacilli that are eliminated from primary lesions in infants and children do not constitute a serious public health menace, because they are eliminated by way of the intestinal tract. The occasional infant or child develops the reinfection type of pulmonary tuberculosis, which may appear as tuberculous pneumonia or as a chronic disease. In such cases there usually is considerable coughing, and tubercle bacilli may be recovered from the sputum. These cases are just as significant from the standpoint of spread of tubercle bacilli to others as open cases of tuberculosis in adults.

In the reinfection type of chronic pulmonary tuberculosis the lesion usually is present a long time before there are any symptoms such as coughing and expectoration. Such lesions usually begin in a very small way and may be present over a considerable period of time before they will cast shadows that can be seen with the naked eye even on stereoscopic x-ray film examination. Even after they become sufficiently large to cast shadows that are easily visualized on x-ray films, there usually is no symptom and therefore no sputum to examine over many months and in some cases over several years. Therefore tuberculosis may exist in a progressive form without any demonstrable tubercle bacilli in the sputum. In the days of Koch and Trudeau, the finding of tubercle bacilli in the sputum of a person who was not seriously ill was sometimes the first definite manifestation of tuberculosis, that is, physical signs were absent, as well as significant symptoms. However, since that time our diagnostic aids have improved to such an extent that the disease can usually be diagnosed long before the sputum is positive.

It is true that, in the occasional case, tubercle bacilli may be found in the sputum even in the absence of clinical symptoms, physical signs, or demonstrable shadows on the x-ray film. Probably in such cases the bacilli are liberated from caseous lymph nodes that have ruptured into a bronchus or one of its ramifications and continues to feed tubercle bacilli into the bronchial tree. While such cases apparently are rare, nevertheless they emphasize the importance of making complete examinations of the sputum for tubercle bacilli in every person who has a cough and expectoration.

A satisfactory way to collect a specimen of sputum is to have the patient expectorate into a container in which has been previously placed a few cubic centimeters of a 5 per cent solution of phenol. This suffices to kill any bacilli that may be present and yet does not destroy their staining qualities. Thus, the sputum is rendered harmless to those who subsequently work with it. When tubercle bacilli are not found in direct smears from specimens collected in this manner, one should then collect in a sterile empty container all the sputum for twenty-four hours or longer. In this the bacilli remain alive and the specimen may be treated by the various methods preparatory to guinea-pig inoculation, implantation on culture mediums, and so on. When only direct smear examinations are to be made it is usually thought best to collect the first sputum expectorated on awakening in the morning.

If one depends on the staining of direct smears of sputum even when tubercle bacilli are present, they are often entirely overlooked. This is not difficult to understand when one considers the small amount of sputum examined under the microscope. Therefore, a single negative finding is of no value. Corper (The Certified Diagnosis of Tuberculosis, THE JOURNAL, Aug 11, 1928, p 371) has shown that in order to find tubercle bacilli by microscopic examination of stained smears there must be approximately 100,000 tubercle bacilli in a single cubic centimeter of sputum. Special methods of examination have been devised such as the anti-formin method, which consists of collecting the sputum for two or three days, then adding to the total amount 15 per cent by volume of anti-formin (a preparation consisting of a mixture of sodium hydroxide and sodium hypochlorite and obtainable from commercial houses). This reduces the consistency of the sputum to fluid which should be thinned with alcohol or water and centrifugated. The sediment collected is washed in water, centrifugated again and from this smears are made, which are stained in the usual way. Not infrequently bacilli are demonstrated in this manner when it is impossible to find them by the direct smear method. The dilution flotation method described by Pottenger (*Am Rev Tuberc* 24 583 [Nov] 1931) has been found to be a very accurate, quick method for detecting tubercle bacilli when only a few are present in the sputum.

Guinea pig inoculation has become a standard method in diagnosis. It consists of introducing approximately 0.5 cc of sputum subcutaneously into the inguinal region of the animal. From about fourteen to twenty-one days later the intracutaneous tuberculin test is administered. If the test has become positive in animals that were previously negative to the test, it is good evidence that the sputum introduced contained tubercle bacilli. Confirmatory evidence may be obtained by post-mortem examination of the animal after four or five weeks.

Culture mediums have been extensively used because they are accurate, simple and inexpensive. As sputum frequently contains many other micro organisms, one can destroy them for the most part by treating it with 4 per cent anti-formin. After an hour the material is centrifugated, and the sediment is planted on laboratory mediums. Anti-formin may be dispensed with if Petroff's medium, which contains gentian violet is used. This inhibits the growth of micro organisms other than tubercle bacilli and, therefore, permits one to plant sputum directly on it.

EFFECTS OF COLD APPLICATIONS ON HEAD INJURIES

To the Editor—Relative to the use of ice irrespective of the method employed in head injuries will you kindly inform me on the following points: 1 To what approximate depth (ice thoroughly applied) does the effect of this therapy penetrate? 2 Are the beneficial results to deeper brain substance obtained by continuous blood flow from periphery to center? 3 Knowing that ice applied as stated violently constricts the superficial capillaries and other blood vessels near the surface is there a possibility of producing further engorgement of the deeper structures and in this manner defeat at least in part the results intended? 4 Is atropine indicated to promote marked and general capillary dilatation thereby relieving deeper engorgements? 5 Cannot the skin take care of a great volume of blood for an indefinite period without damage resulting?

W T ARNOLD MD Hemphill Texas

ANSWER—1 Ice applied to the skin and body does not cause cold to penetrate to any great depth. It is diffused by the blood supply. The literature on the question of penetration of cold is varied.

Levton and Sherrington (*Quart J Exptl Physiol* 11 214 1917) demonstrated that an ice bag applied to the skull might change the intradural temperature through a range of 5 to 6 degrees centigrade.

Bernhard Zondek (*Munchen med Wchnschr* 57 810 [July 9] 1920) showed that an ice bag applied one hour over the human thigh lowered the skin temperature from 34.8 to 7 C and the

deep muscle temperature (5 cm deep) from 37.1 to 36.3 C. He also introduced his thermometer into the psoas muscle just posterior to the peritoneum. An ice bag over the hypogastrium for two hours produced a drop of 4.5 degrees centigrade.

Selling Brill (*Ann Surg* 89 857 [June] 1929) reported observations on effects of an ice bag on the abdomen of a dog and showed that it had little effect on the intraperitoneal temperature the greatest fall being 2.5 degrees centigrade, which was observed in one instance.

2 Yes

3 The capillaries may be violently contracted by the application of ice. This, however, is counteracted by the increased blood flow to counteract the effect of the ice. Lewis (*Brit M J* 2 61 [July 10] 1926) showed that on the application of cold the number of skin capillaries remaining open and active usually decreases and that the rate of flow usually slows. If the part is suddenly dipped in ice water the effect in many cases may be the activation of many more capillaries with a markedly increased rate of flow. This is apparently an attempted compensatory reaction.

4 It is questionable whether there would be deeper engorgement. It is doubtful that atropine would have any effect on it.

LATENT SYPHILIS

To the Editor—A patient 62 years of age contracted syphilis innocently six years ago. The diagnosis was not made until January 1935 when the only symptom was a dry hacking cough and the blood test found to be four plus (Kahn). Treatment has consisted of thirty-two intravenous injections of neoarsphenamine 0.6 Gm alternated biweekly with thirty-two intramuscular injections of sodium bismuth thio glycolate 0.2 Gm representing 76 mg of metallic bismuth and potassium iodide 15 grains (1 Gm) orally daily. When half of this continuous treatment had been completed and the serologic reaction was still positive it was thought wise to give the injections in individual courses instead of in alternating doses and so six injections at weekly intervals of neoarsphenamine were given after which an acute fulminating impetiginous eruption occurred on the face involving one eyelid. This necessitated hospitalization for a few days. With rest there was no improvement when all medication was stopped but when a dose of neoarsphenamine was given the impetiginous eruption cleared up promptly. It was therefore considered due to syphilis rather than to overtreatment with heavy metals. Since that time there has been a constant simple form of conjunctivitis and a rhinitis and bronchitis (unproductive). The serologic reaction remains unchanged. The conjunctivitis has now become so alarming and annoying that treatment has been temporarily discontinued. When iodides are given there is a continuous rhinitis even though the dose is small (from 5 to 15 grains). This conjunctivitis necessitates constant wiping of the excessive lacrimal secretions from the eyes the appearance is like that of a hay fever patient and a film of mucus covers the eyes at times impairing vision. The general health of the patient is excellent excepting for some loss of excess weight which is considered favorable rather than unfavorable. The treatment used for the conjunctivitis has been the use of neosalol 10 per cent one drop in each eye three times daily and yellow mercuric oxide ointment placed in each eye at night to prevent the eyelids from sticking together. There are several questions I should like to ask with regard to this case: 1 Should neoarsphenamine and bismuth injections be continued? 2 Because the impetiginous eruption developed six weeks after neoarsphenamine alone had been given without the bismuth compound the remainder of the treatment had been resumed as before alternate doses of bismuth and neoarsphenamine being given. If injections are continued would you consider it better to give these in separate courses? 3 Do conjunctivitis, rhinitis and bronchitis follow overtreatment with these antisyphilitic preparations? 4 The sensitivity of the patient to iodides in that the symptoms grow worse with their use might be considered a contraindication for their use might it? 5 What method of treatment would you suggest to clear up the distressing triad of symptoms conjunctivitis, rhinitis and bronchitis? 6 Examination of the patient reveals absolutely no focus of infection and the organic function of all of the essential viscera is excellent and yet the skin looks scurfy, deeply pigmented, dry, scaly, pruritic, atrophic and blotchy. Do you think this skin condition is due to arsenical therapy? If so do you advise the use of sodium thiosulphate? I think that Queries and Minor Notes is the most interesting and instructive section of THE JOURNAL. Most of my colleagues in practice agree with me on this point and I am glad to see this part of THE JOURNAL expanding.

M D Michigan

ANSWER—The treatment for latent syphilis in a man of 62 must be given with greater caution than in a younger person. This patient obviously has an overtreatment syndrome. Such symptoms as excessive lacrimation, profuse rhinitis and bronchitis are due to intolerance to iodides. An acute impetiginous eruption that clears up after a dose of neoarsphenamine is probably also an iodide eruption and not due to syphilis.

It would appear therefore that iodides are contraindicated in this case. The description of the skin as deeply pigmented, dry, scaly, pruritic and atrophic suggests an arsenical pigmentation and should be a warning signal against further neoarsphenamine injections. The treatment that would seem advisable in the patient's present situation would be a preliminary course of sodium thiosulfate injection intravenously in doses

of 1 Gm in 5 cc of sterile distilled water twice weekly for from six to eight doses, then a rest period of three months and a Wassermann test at the end of this period

If the reaction is still positive, bismuth salicylate should be given in doses of 0.2 Gm for ten doses once a week. Further treatment should consist of alternating courses of bismuth salicylate and a mild mercurial preparation such as mercury with chalk by mouth

VITILIGO

To the Editor—A white woman aged 48 apparently in perfect health for the last six or eight months has had large irregular blotches of depigmentation on the dorsum of both hands but nowhere else. The skin in the affected areas appears almost white contrasting against the neighboring portions of the skin which are normally pigmented but appear brown because of the contrast. When exposed to sunlight the white areas develop quickly an erythema apparently from the lacking protection pigment. She states that the areas affected are becoming gradually larger. What is the cause? What is the treatment? If there is no treatment please give a prescription for a colored ointment or salve that may be put on the depigmented areas

W L BENISHEK M D Aurora Ill

ANSWER—Vitiligo is a chronic skin disease characterized by areas of depigmentation, usually symmetrical, often bordered by a zone of hyperpigmentation. It may appear anywhere on the body, but the backs of the hands are a favorite point of onset. It progresses slowly without subjective symptoms. The cause of vitiligo is not known. The chief theories of its etiology are (1) syphilis, (2) toxic conditions, (3) heredity, (4) trophoneurosis, (5) endocrine disturbance.

1 Syphilis is not accepted by many as the cause of vitiligo. It is regarded by the best authorities as on a par with the other disturbances of metabolism. Gaucher (Sur l'etologie du vitiligo, *Ann de Dermat et Syph* 3 1113 1902) says "Syphilis produces nutritional disturbances like those caused by any chronic intoxication, frequently causing, among other signs, lessened elimination of urea and lower percentage of urinary chlorides. There is nothing astonishing in seeing vitiligo in the syphilitic, for the syphilitic toxins may be of themselves capable of giving rise to pigmentary alterations in the skin."

2 Besides syphilis vitiligo is often associated with lichen planus, psoriasis, typhoid, scarlatina or pernicious anemia, which may precede or accompany its onset. The theory that vitiligo may at times be a manifestation of chronic arsenic poisoning has yet to be proved, in the light of recent knowledge of the unreliability of tests for arsenic. There have been many reports of vitiligo, with or without melanoma occurring as an aftermath of exfoliative dermatitis caused by arsphenamine or related drugs (Cannon A B and Karelitz, Marie B. Vitiligo from Arsphenamine Dermatitis and from Arsenic of Unknown Origin, *Arch Dermat & Syph* 28 642 [Nov] 1933). In view of the well known ability of arsenic and bismuth to upset the pigmentary mechanism, it is not hard to believe that these drugs may have a causative relation to some cases of vitiligo.

3 There have been a few reports of vitiligo occurring in several generations of the same family. The occasional association of vitiligo with retinitis pigmentosa, a disease in which heredity is the chief etiologic factor, strengthens this theory but this does not occur with sufficient frequency to warrant placing vitiligo among the hereditary disorders.

4 Vitiligo is often associated with nervous disease, migraine, melancholia, insanity, tabes dorsalis and toxic neuritis. S W Becker (Vitiligo, *Arch Dermat & Syph* 28 497 [Oct] 1933) mentions its relation to lichen simplex chronicus, general neurodermatitis, neurotic excoriations and dermatographism. He emphasizes the neurocirculatory instability in vitiligo patients with low blood pressure and low basal metabolism and quotes Levy, Franke and Juster's observation of the same capillary constriction in the depigmented zone and in the finger tips as that which has been seen in alopecia areata.

5 Hyperthyroidism is frequently an accompaniment of vitiligo. Jay F Schamberg (in discussion on Lane, J E. Vitiligo and Syphilis, *THE JOURNAL*, July 5, 1919 p 30) reported having seen the two diseases develop simultaneously.

Hypothyroidism is also sometimes associated with vitiligo, and Addison's disease has been noted in association with vitiligo.

Scleroderma, in which hyperpigmentation commonly occurs, has been accompanied by vitiligo in many instances, and the same can be said of morphea. Now that hyperparathyroidism has apparently been implicated in the production of scleroderma, the argument for the endocrine etiology of vitiligo has been strengthened (Leriche, R, and Jung, A. Les traductions tissulaires de l'hyperparathyroidisme dans la sclerodermie, *Presse med*, Aug 31, 1935, p 1361).

Alopecia areata and vitiligo are often seen together, but this does not help much in any decision as to etiology.

The treatment of vitiligo has been generally held as of no value, but recently encouragement has been offered. Lindsay's method of treatment by intravenous injection of gold sodium thiosulfate, though frequently unsuccessful, has had support from the report of J L Grund (Treatment of Vitiligo with Gold Thiosulfate Given Intravenously and Subcutaneously, *Arch Dermat & Syph* 31 867 [June] 1935), who saw distinct benefit from both intravenous and subcutaneous injections.

Ultraviolet radiation used over a long time stimulates pigment formation in most cases. Effects are made to enhance its action by intravenous injection of acriflavine base, beginning with 5 cc of a 0.5 per cent solution in water, repeated every third day, with gradual increase in dosage. Great care must be taken not to get any of the solution outside the vein, for it is very irritating. Albuminuria, nausea, vomiting, headache and fever are possible complications. The patients must be warned not to expose themselves to strong sunlight, and ultraviolet treatments must be given cautiously (Zakon, S J. The Combined Trypaflavine Quartz Light Treatment of Psoriasis Vulgaris, *Illinois M J* 61 444 [May] 1932).

Painting the depigmented areas with an alcoholic solution of oil of bergamot before ultraviolet treatment has seldom been helpful, probably because a sensitization to oil of bergamot is necessary to the production of the dermatitis that brings on the pigmentation.

One of the simplest methods of concealing the white spots is to paint them as often as needed with a 0.25 to 0.5 per cent aqueous solution of potassium permanganate. William Allen Pusey (The Principles and Practice of Dermatology, New York, D Appleton & Co, 1924, p 972) suggests

	Gm or Cc
Glycerin	10 to 40
Zinc oxide	
Calamine powder	aa 120
Water	ad 1200

To this sulfonated bitumen is added until the right shade is obtained (usually from two to fifteen drops).

Bleaching the hyperpigmented border helps to make the depigmented patches less conspicuous. A 30 per cent solution of hydrogen peroxide, 1 part, anhydrous wool fat, 6 parts, and petrolatum to make 10 parts may be applied to a small area once a day. If it causes irritation, one should stop its use and wait for the inflammation to subside. If necessary, the hydrogen peroxide content may be increased.

MORTALITY STATISTICS OF INJECTION WITH NEOARSPHENAMINE AND INJECTION OF VARICOSE VEINS

To the Editor—Kindly quote me mortality statistics concerning the relative risk between varicose vein injection and neoarsphenamine injection. M S, Wisconsin

ANSWER—The mortality statistics of neoarsphenamine injections as compared with fatalities following the injection treatment of varicose veins are difficult to interpret. The arsphenamine mortality has been analyzed by Stokes (Modern Clinical Syphilology, ed 2, Philadelphia, W B Saunders Company, 1934). He gives the following summary of statistics

Year	Author	Injections
1910 1913	Leredde and Jamin	1 3 777
1911 1914	Nichols	1 5 000
1914 1918	British Base Hospital No 39	1 8 000
1917 1919	Guy (United States Army)	1 12 500
1920	Meirowsky (European statistics)	1 11 289
1920	Meirowsky arsphenamine	1 13 000
1920	Meirowsky neoarsphenamine	1 32 530
1920	Meirowsky death rate under 0.6 Gm	1 162 800
1920	Meirowsky death rate over 0.6 Gm	1 3 000
1916 1924	Section of Dermatology (Mayo Clinic)	1 21 000
1919 1927	United States Navy	1 17 526
1925 1931	University of Pennsylvania	1 33 600

The average risk of death (avoidable and unavoidable) ranges according to these figures between 1 7,000 and 1 11,000.

The unavoidable risk of death ranges between 1 56,000 and 1 162,000. Good performance is estimated by Stokes at from 1 15,000 to 1 35,000, depending on material, system and dosage.

It is difficult to differentiate between avoidable and unavoidable deaths. The administration of arsphenamine to a patient with an obvious contraindication may result in death not from the drug but from its improper use. The mortality statistics from varicose vein injections have never been submitted to such a searching scrutiny as those due to arsphenamine. McPheeters reported a death rate of approximately 1 5,000. Kettel estimated the total mortality as 1 3,000. It must be emphasized that these figures represent the number of patients and not the number of injections.

The following data have been summarized from Kilbourne's article (THE JOURNAL, April 20, 1929, p 1320)

Author	Cases	Deaths
McPheeters	53 000	11
Siard and Gaugier	15 000 (120 000 injections)	0
Linsler	15 000 (50 000 injections)	0
Delter	890	0
Douthwaite	2 000	0
Gencyrier	4 000	0
Weisen	2 000	0

Kettel (*Zentralbl f Chir* 58 1498 [June 13] 1931) knew of twenty deaths in 60,000 patients who were treated by injections, a total mortality of 1 3,000 per patient. Half of these deaths were readily avoidable, owing to the use of toxic drugs or improper selection of cases. This would leave an unavoidable mortality of 1 6,000 per patient.

Because of the fact that individual experience with the injection treatment is growing, less toxic drugs are used the importance of excluding patients with latent phlebitis is becoming more common knowledge, immobilization after treatment is avoided and vein ligations above veins suspected of harboring infection are more frequently employed, the mortality rate per injection of varicose veins certainly compares favorably with the percentage of good performance as given by Stokes, namely, from 1 15,000 to 1 35,000 per injection, as most patients receive from ten to thirty injections during treatment.

These figures emphasize that caution is necessary in interpretation and that average performance throughout the country is far better today than it was ten years ago. Large individual statistics may still be found without a single mortality. Because of the difference in clinical material age groups and drugs further comparison is not profitable.

HYPOTONIA AND PARALYSIS AFTER SUBARACHNOID INJECTION OF ALCOHOL

To the Editor—A man aged 45 with a negative Wassermann reaction and no detected tuberculous infection has retention of the urine and of the bowel contents as the result of hypotonia following subarachnoid injection of 10 minims (0.6 cc) of 95 per cent alcohol. His family history is negative. He had the usual childhood exanthems. He never had any cord lesions as a child. Five years ago an iron spike was driven deep into the right buttocks and this laid him up for several days. A few weeks later he began having sciatic pain. He has had occasional colds and grip. He has not had pneumonia or venereal diseases. The present trouble started five years ago as sciatica diagnosed by several doctors in private practice and at clinics. He has several teeth that probably carry infection but have not been roentgenographed. The blood pressure is 138 systolic 84 diastolic. The pulse rate is 82. He is nervous. He walks with a lump and a forward stoop favoring the painful right leg which pains excruciatingly from buttock to ankle posteriorly following the course of the sciatic nerve. Otherwise his physical condition is normal. He has been given scores of medicines during the past five years. Lately he had 40 cc of physiologic solution of sodium chloride injected around the sciatic nerve at a point joining the fold of the gluteal muscle but this gave no satisfactory result. Following the advice of several physicians he was given 10 minims (0.6 cc) of 95 per cent ethyl alcohol fifteen days ago through the third lumbar interspace. A medium size spinal puncture needle was used and the duration of the injection was three and a half minutes while he lay on his left side and in a 20 degree Trendelenburg position. He was not permitted to get up for seventy-two hours. During the first twelve hours he lay with the hips slightly elevated. He also lay on his left side for the first six hours with occasional leanings on the back and stomach. The pain disappeared almost at once after the injection. Incontinence of urine and of the bowels persisted for twenty-four hours. Then retention developed and is yet present. The left knee jerk is present but not the right. There is light anesthesia to a pin point over the third and fourth sacral segmental areas of the skin which is complete except for smaller areas on the left side. Anesthesia of the skin passed farther down the posterior surface of the thigh but this is less now. Muscle power is gradually but slowly returning in the right limb although the knee often buckles under him. He can localize deep pressure of the finger on the muscles of the limb but he cannot direct the movements of the right leg with his eyes shut. When sitting on a chair he says that he has the sensation of having the testicles under pressure as though they were being squeezed. The sole of the right foot is very sensitive and recently it has had a disagreeable burning sensation. The left limb is normal. The patient is very nervous and restless. There is no fever pulse and blood pressure are normal. He feels the discomfort from retention in the bladder and lower part of the bowel but he cannot pass the urine voluntarily. Please comment on prognosis as to bowel and bladder. What can be done to hasten the return to normality? Kindly omit name and address.

M D New York

ANSWER—When strong alcohol comes in contact with sensory nerve fibers it produces anesthesia and relieves pain in the area of the blocked nerve. Similarly it causes paralysis and subsequent atrophy when brought in contact with motor nerves. Consequently unless paralysis of the legs and sphincter disturbance already are present an injection such as the one given in this case should not be made without having the patient

understand that relief from pain is likely to be obtained only at the price of paralysis. It is unfortunate that recent writers have spread the belief that injections of this kind can be given without considerable risk of paralysis. One need only recall the extensive experience with alcohol injection for trigeminal neuralgia which has shown that whenever the alcohol has accidentally reached such motor nerves as the third sixth and motor branch of the fifth nerve paralysis of more or less prolonged duration has invariably occurred. In this case, in which probably only the fibers of the cauda equina were reached and not the spinal cord itself it is likely that there will be recovery from the paralysis and sphincter disturbance within six months.

DIAGNOSIS OF UNUSUAL ERUPTION

To the Editor—Miss A K aged 19 white and single complains of having had for the past six years on changes of weather from warm to cold or dry to moist a rash located over the extensors of her fingers of both hands and over her lower extremities from the toes to the lower third of her thighs. The rash appears to be like a blister lying on a red base but on palpation hard to touch. With the appearance of the rash the areas involved itch intensely. With a change back to warm or dry weather the rash spontaneously disappears leaving no discoloration or changes over the involved areas. Physical examination is negative. I have not seen the rash but have described it as learned from her history. What is the possible cause of the condition? What can be done in the way of treatment? What is the prognosis? Kindly omit name.

M D New York

ANSWER—Three possibilities suggest themselves (1) a contact dermatitis, (2) erythema multiforme, (3) dermatitis herpetiformis.

1 A contact dermatitis would be due to sensitization to some material with which the patient comes in contact only occasionally. Does she wear different clothing in cold damp weather? Her daily habits must be examined minutely to reveal every unusual contact. The change of weather may be only a coincidence, not as regular as the patient thinks. Patch tests should be made between attacks to discover the one or several sensitizations. The vesicles of a sensitization dermatitis are very superficial and are easily ruptured. The report of a hard blister-like eruption need not mean actually a vesicular one for patients frequently use that term in describing wheals or papules.

2 Erythema multiforme might have this distribution, though in repeated attacks it ought to involve the backs of the hands or the mucous membrane of the mouth to some extent. Itching is unusual in erythema multiforme.

3 Dermatitis herpetiformis would seldom involve the same areas on successive attacks and would not be likely to clear completely between attacks as this does. It often is vesicular, but the vesicles are not hard.

It is manifestly impossible to venture any diagnosis on so meager a basis. The doctor should see his patient during the next period of cool damp weather and get a first hand idea of the eruption.

VACCINES IN ARTHRITIS

To the Editor—I have a patient who has a form of chronic arthritis in whom under ordinary circumstances I would use the streptococcus vaccine (intravenous) of Clawson and Wetherby. This patient however is quite fleshy and it is practically impossible to see any veins in her arms. I would appreciate your telling me what preparation could be used for this purpose either subcutaneously or intramuscularly. Please omit name.

M D Michigan

ANSWER—There are many streptococcus vaccines or allied substances available for the treatment of chronic infectious (atrophic proliferative rheumatoid) arthritis, such as the vaccine of Cecil (New York), of Rosenow (Rochester, Minn.), of Swift (New York) of Crowe (London) and the antigen of Small (Philadelphia). These can be obtained at little expense from their originators some are commercially available. Some of them are usually given subcutaneously. Those which are generally prescribed intravenously can be given subcutaneously also, as a rule. However Clawson and Wetherby have argued that subcutaneous administration is likely to increase rather than decrease a patient's hypersensitivity to streptococci and that the intravenous method is more likely to produce desensitization. The basis for their belief is derived from animal experiments and from agglutination tests and tests of cutaneous sensitivity of debatable significance. The statement that the subcutaneous administration of small doses of the vaccines mentioned is often or regularly likely to produce recognizable clinical hypersensitivity and unfavorable effects is not borne out by the facts and observations from much clinical experience.

While each of the originators is inclined to believe (or hope) that the method of selection and preparation of his respective

vaccine has made it more nearly specific than that of others, it is the opinion of disinterested observers of wide experience that regardless of the choice of vaccine or its method of administration results are generally similar. All these vaccines are somewhat alike, all are probably relatively (although not entirely) nonspecific, and all probably produce (in suitable individuals at least) some degree of what is called, for lack of better knowledge, "nonspecific desensitization." Current preference for small doses, to avoid constitutional or focal reactions, seems well founded.

TATTOOING OF EYES

To the Editor—A man aged 35 received a blow in the left eye five years ago. He has total loss of vision and cannot even recognize light. There is no pupil. The cornea is a light faded blue. Before the accident the cornea was a deep blue. The eye is conspicuous chiefly because of the light cornea. Is there any way to have this blind eye tattooed in the region of the cornea with a blue pigment so that the blind eye will match the normal eye? If so where is the work being done and who is capable of doing it?

M D Pennsylvania

ANSWER—If the iris alone has faded nothing can be done to improve the appearance. If the cornea is bluish white (the iris not being seen through the scar) a central round tattooed area giving the appearance of a black pupil will improve the appearance. There has been no satisfactory color tattooing of the cornea. Dozent Guist formerly of the second eye clinic in Vienna, experimented with various reagents to produce color with little or no success. Only dark brown (from gold chloride) or black from platinum chloride have been used with success.

TREATMENT OF PYELITIS

To the Editor—The patient I am writing about is 26 years of age is married and has one child a year old. This is the second attack of pyelitis the patient has had since childbirth. She had two similar attacks about six years ago and one at the age of 3. The urine is full of pus. Pain is present in both flanks. The reaction of the urine is slightly alkaline as a rule. Culture of the urine shows *Bacillus proteus*. Intravenous pyelography shows complete double ureters on both sides with no obstruction. Bacilluria is present even after the urine is clear microscopically. Treatment has consisted of alternate alkalization and acidification (degree not determined) of urine forcing fluids, halibut liver oil or carotene. The ketogenic diet has not been tried. Could you suggest any line of therapy that might clear up this bacilluria? The patient is at present in bed. Kidney lavage has been done on previous occasions with resulting clearing up of the pyuria but not the bacilluria. Any help would be greatly appreciated. Do you think autogenous vaccination might help?

M H SCHNEIDERMAN M D Philadelphia

ANSWER—Urinary infections with *Proteus vulgaris* are more difficult to cure than *Bacillus coli* infections. The fact that the infection has been repeatedly reduced to a bacilluria makes it possible that ammonium chloride (enteric coated pills), 1 Gm four times a day, and increasing doses of methenamine, starting with 0.3 Gm four times a day and increasing to 0.65 and 1 Gm, may cure the disease. The value of the autogenous vaccine in proteus infections is questionable.

If unsuccessful, the ketogenic diet should be tried. A practical form of ketogenic diet compiled by the Section on Urology and the Rochester Diet Kitchen is helpful in arranging this diet. Further suggestions may be had from the article "The Ketogenic Diet in Treatment of Bacillurias in Females," by C N Cook (published in the *Journal of Urology* 32 153 [Aug] 1934).

ZINC IONIZATION IN HAY FEVER

To the Editor—Kindly inform me as to the status of the zinc ionization method of the treatment of hay fever. Does it give permanent results? Kindly give references. Also is there any advantage in the use of mechanical devices such as Filteraine in the relief of symptoms of hay fever? Please omit name.

M D New York

ANSWER—The zinc ionization method for the treatment of hay fever has been used by many physicians but there is no unanimity of opinion. Many individuals are helped a great deal others are moderately improved, a third portion state that they see no improvement whatever. Not many report that the results are permanent much beyond the season for which the treatment is being given. Here and there are statements made that the patient is relieved for a number of years. From time to time untoward results are reported. If the treatment affects the olfactory nerve and it does so occasionally, anosmia results. Some people complain of inability to tolerate the presence of smoke after the ionization treatment and on a number of occasions with the cessation of nasal symptoms following ionization asthma has set in promptly. Of course, it is not

possible to state absolutely that the onset of asthma was due to the treatment, but time and the comparison of notes of many men may be important in this regard.

Any adequate device that filters the major portion of dust and pollen from the air is helpful and makes sufferers of hay fever feel more comfortable.

DANGERS OF SELF TREATMENT WITH IODIDES

To the Editor—Newspaper clippings entitled "For Better Metabolism and The Tired College Girl" by Dr William Brady (66 Agassiz Circle Buffalo) both recommending that every one take a definite ration of iodine at regular intervals have been brought to my attention by patients. Dr Brady offers to send instructions for taking a suitable iodine ration to any one who requests them and encloses a stamped self addressed envelope. He recommends that adults take one drop of tincture of iodine in a glassful of water each day in each third month. He states that this often works magic in cases of a chronic tired feeling and lack of usual or former ambition energy or pep with little refreshment from rest or a vacation a tendency toward accumulation of flabby excess weight depression of spirits or melancholia premature aging graying and falling of the hair poor circulation or mental torpor. Dr Brady also says that it may prevent high blood pressure or postpone hardening of the arteries. Is there any recognized basis for these statements? There seems to be no substantiation of them in the medical literature. Hartsock (*The Journal* May 1 1926, p 1334) states that the continuous use of iodine over a long period of time should never be prescribed for adults and when its periodic use is prescribed frequent observations of the pulse and weight should be made. Please omit name.

M D, Washington

ANSWER—Hartsock's statement is much more competent than that of Dr Brady. Advice by mail for any kind of condition is properly frowned on, and the "absent treatment" by iodide is a good example of possibly pernicious therapy, when one thinks that "the tired college girl" might be suffering the early stages of tuberculosis or be on the verge of neurasthenia from unhygienic living, neither of which conditions would be helped by Dr Brady's advice and both of which would be harmed by delay in instituting the proper treatment.

CHRONIC GONORRHEA

To the Editor—I am writing to inquire as to further treatment that may be tried in a patient aged 34 who contracted gonorrhea in 1929 and was actively treated by his physician first by irrigations and later by massage sounds and vaccines. Since then he has received all the methods of treatment both vigorously and with rest periods and yet he complains of a morning discharge which sometimes is quite profuse. Smears are negative for the gonococcus. The prostate strappings are clear. Preputial infection has been ruled out. An endoscopy revealed granulation tissue and nothing else. The prostate feels normal as do also the testicles and the epididymis. All sorts of antiseptics and even diathermy have failed. There is no stricture. Any suggestions would be greatly appreciated. Kindly omit name.

M D Pennsylvania

ANSWER—If there are granulations in the urethra, these are frequently the cause of prolongation of a discharge and should be destroyed. This can be accomplished either by direct application of a fairly strong solution of silver nitrate through the urethroscope or by repeated instillations of a mild solution of silver nitrate. Some patients continue to have a discharge from protracted and too energetic treatment. When the granulations have disappeared it might be well to give the patient a long rest omitting all forms of treatment.

INHALATION ANESTHESIA IN WHOOPING COUGH

To the Editor—In the January 11 issue of *THE JOURNAL* under Queries and Minor Notes inhalation anesthesia in whooping cough is discussed. In connection with this query the following report is of interest.

Quite a few years ago I saw a patient about 10 years of age having a terminating attack of appendicitis. He was in about the third week of a very severe attack of whooping cough with spasms of coughing every few hours. His attending physician stated that it was one of the most severe cases he had ever seen. Operation was imperative and ether was administered. The anesthesia proceeded smoothly and a gangrenous appendix was removed. The patient had no respiratory difficulties during the operation. About six hours after the operation he had a very mild coughing spell but never had any further attacks. Apparently his whooping cough was cured and he made an uneventful recovery.

With this very favorable experience in mind I tried to extend the etherization to other whooping cough patients but had no opportunity to do so.

Book Notices

Length of Life. A Study of the Life Table. By Louis I. Dublin. Ph.D. Third Vice President and Statistician Metropolitan Life Insurance Company and Alfred J. Lotka. D.Sc. Assistant Statistician Metropolitan Life Insurance Company. Cloth. Price \$5. Pp. 400 with 53 illustrations. New York: Donald Press Company, 1936.

This is a reference book for the public health official, the health educator, or the physician who has frequent occasion to refer to facts relating to longevity. It is an interpretation of the life table for the nontechnical reader with certain information on the construction of life tables for the statistician who deals in a relatively simple way with the facts concerning length of life. The authors have achieved the difficult aim of showing with the aid of numerous tables and graphs that "human life is a very personal affair." They have discussed in an interesting way the life span, mean length of life, life tables antique and modern, gain in life expectancy at various ages but especially at birth, and the geographic, biologic and hereditary aspects of longevity. Recognizing the unpractical nature of the advice to make a wise choice of grandparents they seem unable nevertheless to find in their statistics any better assurance of a long life. The contributions of medical and sanitary science to longevity and, of course primarily to increasing the mean length of life rather than the ultimate span thereof are interestingly though briefly outlined. The authors agree with other observers that ancient man, as far as the meager records available make estimations possible seems to have had as long a span of life as modern man, and perhaps longer once he got past the extraordinarily severe hazards of birth and infancy that prevailed in ancient and medieval days. Relationship of longevity to occupational hazards, to physical defects to population problems and to economic problems form the subjects of later chapters. Perhaps few readers will wish to read this book at a sitting, yet it deserves something more than a mere place among the statistical tables, of which it presents many and excellent, and the graphs with which it abounds for the authors have succeeded in making the subject entertaining even though statistical. There is a good index.

Pollen Grains. Their Structure Identification and Significance in Science and Medicine. By R. P. Wodehouse. Ph.D. Scientific Director of the Hayfever Laboratory the Arlington Chemical Company, Yonkers, New York. Cloth. Price \$6. Pp. 574 with 123 illustrations. New York & London: McGraw-Hill Book Company, Inc. 1935.

This is an exhaustive study of the history and basic principles of pollen morphology, with a key and descriptive classification of the pollen grains of 450 species of the wind pollinated plants of North America. Accompanying the text, but not in a convenient position for comparison with the descriptions, are beautiful enlarged drawings of the pollen grains of about a third of the species discussed. Considerable space is devoted to the genesis and phylogenetic significance of pollen grain characters. Even the eternal question of heredity versus environment is not overlooked, as evidenced by "Inasmuch as the numerical type of symmetry of the pattern is determined by the position and number of the germinal apertures, it may be stated that the number and arrangement of the elements in the symmetry patterns of pollen grains are haplotypic characters that is to say, are the result of their cellular interrelations and directly due to the conflict of the law of bipartition with rectangular intersection, in opposition to the tendency to assume the least-surface configuration." In the orderly development of the author's conclusions he allows himself only occasional diversions. At the end of the historical review, which strangely enough does not include any of the contributions to the subject during the past forty years, the author allows four pages to a description of his methods used in mounting and staining pollen grains and four pages to directions for collecting pollen in large amounts. The short chapter contributed by Dr. Erdtman on fossil pollen statistics and the eighteen pages devoted to an elementary discussion of the role of pollens in the causation and diagnosis of hay fever, which are obviously intended to justify the subtitle of the book, could well be left out without detracting from its usefulness. The practical application of pollen grain identification is suggested in a chapter discussing the author's study of the pollen content of the air in his own home city. The book will be of only academic interest to physicians not specializing in allergy. It will be of great value to those allergists who

have the time and facilities for pursuing the critical study of pollen morphology. While the author strongly favors the examination of pollen grains in their moistened and expanded condition and has so drawn most of his illustrations, he usually mentions their characteristics as seen in their dry form. The book will thus be found useful to those who are familiar with the widely used method of atmospheric pollen study with slides coated with petrolatum or other oils that do not expand the pollen grains caught on them.

Recent Advances in Laryngology and Otology. By R. Scott Stevenson. M.D. Ch.B. F.R.C.S. Surgeon Metropolitan Ear, Nose and Throat Hospital, London. Cloth. Price \$5. Pp. 346 with 128 illustrations. Philadelphia: P. Blakiston's Son & Co. Inc. 1935.

The literature in the field of otolaryngology, rhinology and laryngology as in the other specialties has grown both in this country and abroad to large proportions. To be fully cognizant of it would require the reading of a considerable number of foreign and domestic journals limited solely to the special field, not to speak of those pertaining to related subjects. It would, of course, be easy to dismiss the whole affair by saying that much of what appears in print is relatively unimportant and repetitious. This attitude would express, however, less than half the truth. In otology, rhinology and laryngology there is a new and enthusiastic attitude in the past few years indicative of a real advance in the knowledge of the difficult problems facing the specialty. For example, much is being said and written of carcinoma of the upper air and food passages, and rightly so. The malignant growths in this area have been recognized as being often of a highly radiosensitive nature, and their reaction to radium and roentgen therapy is frequently most encouraging. The work of Hilding and others on the nature of ciliary action has revived the interest of all in the physiology of the nose and accessory sinuses. Weaver and Bray at Princeton some years ago exposed the auditory nerve in cats, placed suitable electrodes on it, and by means of proper amplifying apparatus were able in a distant sound proof room to reproduce sounds spoken into the anesthetized animal's ear. These studies immediately stimulated an intense investigation here and abroad in a renewed effort to clarify the fundamental nature of hearing. In order to keep abreast with all the new and important advances, those interested turn to yearly reviews, which are helpful though they can give only the transient point of view. The author has covered the ground over a period of years, giving him the opportunity of more mature judgments. His selection of topics of importance is excellent. Continental, British and American opinion is consulted. Considering the large field he had to cover, he has done extremely well, ranging as he does from agranulocytosis to cancer of the larynx, bronchoscopy and esophagoscopy, cardiospasm, chronic nasal sinusitis, hearing tests, the mechanism of the labyrinth and numerous other conditions. If there is one topic left out, it is suppurative of the petrous portion of the temporal bone, which will undoubtedly appear in the next edition, which this wholly satisfactory review deserves.

Chronic Streptococcal Toxaemia and Rheumatism. By J. D. Hindley. Smith, M.A. M.R.C.S. L.R.C.P. Cloth. Price 7s. 6d. Pp. 245. London: H. K. Lewis & Company Ltd. 1935.

The purpose of the book is not definitely stated in the author's preface or foreword, and a reading of it does not make clear just why it was written. The first chapter discusses in broad vague and general terms the subject chronic toxæmia of various sorts, including acid toxæmia. The second chapter deals in the same general fashion with chronic infectious toxæmia. Some cursory remarks on streptococci make up chapter 3. The author believes that, of the infectious toxæmias, the toxæmia attributable to streptococci is most widespread and most important yet least well defined. Chronic streptococcal toxæmia may lead to a life of chronic disability and invalidism from youth to old age. Its manifold symptoms appear during the three stages of the disease and are listed in chapters 4, 5 and 6. The symptoms which "the streptococcal child" (sic) and the older victims of streptococcal toxæmia are likely to present are, according to the writer, indeed numerous and arise from disturbances of any or all functions and tissues of the body. From the title of the book and from a remark here and there one is led to believe that "chronic rheumatism" and "arthritis" are frequent manifestations of this toxæmia. Incidentally nowhere is any attempt made to

define the terms "chronic rheumatism" or "arthritis" further, indeed, little is said about them. In the last chapter entitled "Summary and Conclusion," one gets a little better idea of what the writer is driving at. The author says that he has taken cultures of the nasopharynxes of an unstated number of normal persons and of persons who gave evidence of having chronic toxemia. The normal nasopharynx contains a mixed flora only 5 to 10 per cent of the organisms of which are streptococci. Among patients affected by chronic toxemia nasopharyngeal cultures may reveal organisms from 40 to 100 per cent of which are streptococci, often of the hemolytic variety. Such a "positive streptococcal index" presents evidence that the patient's immunity mechanism is somehow at fault and that that patient is a victim of, or a candidate for, chronic streptococcal toxemia. The author's treatment includes chiefly "immunization by the use of small doses of streptococcus vaccine, preparation of which is not described, elimination of bacterial toxins by nasopharyngeal washings and attention to diet, to the bowels, to foci to 'endocrine deficiency' and so on. No statistics on results are given. The book represents a hodgepodge of generalities and theories, of well known facts and unprovable hypotheses. Much of it is borrowed material and what is presumably original is not backed up by data, figures or proof of any sort.

Medical Social Work. A Study of Current Aims and Methods in Medical Social Case Work. By Harriett M. Bartlett. Paper. Price \$1 Pp. 923. Chicago. American Association of Medical Social Workers. 1934.

This study of current aims and methods in medical and social case work is a report of the Committee on Functions of the American Association of Medical Social Workers in which there is a discussion of medical social work in relation to social case work and clinical medicine, and the role of the medical social worker in study and treatment.

Through the report there appears to be a friendly and understanding attitude toward the medical profession. Such statements as "since coordination is essential it is important to emphasize the point that the physician always remains the leader of the team" seems to indicate an attitude of helpful assistance rather than of independent domination.

It is recognized that the problems with which the medical social workers are concerned grow out of illnesses and are only partially related to economic needs. The medical social worker endeavors to individualize in the study of these social difficulties. If all the recommendations and illustrations in the report represent the actual practice in this field, qualifications for competent medical social workers should be high.

It appears that medical social workers are endeavoring to establish themselves as a new profession and the author complains in one section of the report that the report of the Committee on the Costs of Medical Care, although permeated with a social point of view, barely makes mention of medical social service. This the author feels "suggests that the medical social worker has not yet adequately interpreted to either the medical profession or the public her possible contribution to the development of social medicine. The approach to medical social problems involves a recognition and interpretation of the emotions, mental attitudes, environmental disturbances, psychologic concepts, functional and mental disturbances, and other social factors surrounding and affecting the patient. In an attempt to develop methods of study and work, medical social workers have found it necessary in many instances to construct their own terminology. There seems to be a desire to attempt to apply orderly methods of thinking to accumulated experience. Thus by experimentation, test and evaluation of results the medical social worker aims to contribute to the attainment of a professional status.

The efforts of the medical social worker 'are directed toward enlarging the understanding of the medical social factors and assisting patient and physician to integrate them into a broader and more effective plan in which she herself undertakes by joint agreement, treatment of the social difficulties.' The medical social worker conceives her function to be that of recognizing primarily the inner needs of the sick person. She is concerned however, not only with persons but with ideas and in defining her role in any case must face the problem of objectives, prognosis and the evaluation of results all of which depend on sound methods of thinking.

If medical social work can be closely coordinated with the practice of medicine, serving both patients and physicians as an auxiliary or supplementary assistance it will find many fields of usefulness. It is well to bear in mind, however, that medicine should serve as the primary agent in the application of appropriate remedies for the sick, and that medical social work should be utilized when desirable as a helpful supplement.

Die Zahnheilkunde im achtzehnten Jahrhundert. Ein Stück Kulturgeschichte. Von Hedvig Lidforss Strömberg. Paper. Pp. 232 with 53 illustrations. Copenhagen. Levin & Munksgaard. 1935.

Good textbooks dealing with the history of dentistry are scarce and this book is a welcome addition. As the author states the eighteenth century is a critical period in the evolution of dentistry, one of rapid development following a long period of stagnation. Indeed, the crest of achievement of this century was not surpassed until the last half of the nineteenth century produced the dental engine, anesthesia and antiseptic methods of treatment. The French contributed the most to this progress through the influence of Fauchard both as a practitioner and as an author, his *Le chirurgien dentiste* has been called the most famous dental book. To no little degree two other Frenchmen, Bourdet and Jourdain, added to the luster of France. The *Surgeon Dentist* was published first in 1728 with new editions in 1746 and 1786 and was translated into German in 1733. In addition to Fauchard the author refers most often to the books of Berdmore and Pfaff, these three dentists were employed respectively by the royal families of France, England and Prussia. On the whole the selection and arrangement of the material in this book is to be commended. As the result of a defect in the plan there is some overlapping of chapter contents it is a matter of regret that nothing new is presented with reference to the porcelain controversy. There is an excellent bibliography and a short biography of each dentist or scientist mentioned in the text, both of which are placed at the end of the book, there is an index of the illustrations but none of the subject matter. The German of the text is relatively easy reading and the book, therefore, is commended to both those interested in dental history and those searching for suitable reading to attain facility in German.

A Text Book of Surgery for Dental Students. By C. Perchal Mills. M.B. B.S. F.R.C.S. Honorary Surgeon General Hospital Birmingham and Humphrey Humphreys O.B.E. M.C. T.D. Lecturer on Dental Anatomy Birmingham University. Fourth edition. Cloth. Price \$5.14s. Pp. 342 with 63 illustrations. Baltimore. William Wood & Company. London. Edward Arnold & Co. 1935.

The purpose of the book is frankly stated in the preface. 'In preparing the fourth edition of this book the authors have carefully preserved its original character as a work designed solely for students and practitioners of dental surgery. Surgical progress and the helpful criticisms of examiners and colleagues have led to the inclusion of many new sections and to much revision of old ones but owing to changes in the syllabus of the Royal College of Surgeons, certain omissions have been possible and the book is not increased in size. It will be found to cover the requirements of the Royal College, and of those universities which publish a detailed syllabus.' The book is a brief summary of the most essential facts that will enable an applicant to pass a licensing examination with the least possible effort. Why it should be called surgery is doubtful as it is a mixture of bacteriology, pathology, surgery and various other subjects in about twenty chapters. Most of the material is clearly expressed in compact form, and it is admirably adapted to its avowed purpose. The chapter on fractures of the jaw is distinctly archaic and contains little or nothing with regard to modern methods of treatment.

In the October issue of the *Journal of the American Dental Association* an editorial entitled 'For Dental Students' stated that 'The texts so named are one or another of the basic sciences for dental students. For the most part they are sketchy things, lacking in continuity, without breadth of foundation, books that give results with half explained or unexplained causes that stock the memory with a chaos of data partially or wholly unassociated and therefore unusable. They hark back to the days when courses in the sciences were skeletons of courses prepared for men who obviously would spend their days at the mechanics of dentistry without a disturbing

thought of bacteriology or pathology." At the present time the demands of dental practice require that the training in the fundamental medical sciences, while not necessarily identical in content, must be the same in quality for medical and for dental students. Unless this is true, there is no justification for the increased length of dental education. It is doubtful whether the present volume will be of much assistance to the dental student of today.

Über die Rhythmik der Leberfunktion des Stoffwechsels und des Schlafes Von Erik Forsgren. Paper. Price 6 50 kroner. Pp 56 with 14 illustrations. Stockholm: Isaac Mareus Boktryckeri Aktiebolag. 1935.

This small monograph summarizes the highly creditable research work of the author and his collaborators on the rhythmic nature of liver function. They have found that during the twenty-four hours of each day the liver passes through two opposing phases or cycles of function. Each cycle begins where the other leaves off, rises to a climax and gradually subsides, to merge into the initial stage of the other cycle. These cycles may be called the assimilatory and the secretory phases respectively, and they vary as regards the time of occurrence in different species and even in different individuals of the same species. In man the assimilatory phase usually occupies the hours between 8 p. m. and 8 a. m., while the secretory phase occurs between 8 a. m. and 8 p. m. During the former phase the liver stores glycogen, water and protein and becomes correspondingly larger and heavier. Its bile content is at a minimum. During the secretory phase the glycogen and protein content of the liver falls, it gives up its water stores and the lobules show an increased bile content. These two phases are reflected in the hourly variations of water, nitrogen and urobilin excretion and also in fluctuations of body temperature. Apparently, the rhythm of liver function is to some extent an inherent property of the organ. It is not, for example, greatly dependent on food intake. The author discusses the application of these observations to certain aspects of carbohydrate metabolism and diabetes mellitus. It is obvious that the phenomena of storage or excretion of metabolites, the majority of which directly or indirectly involve the liver, should be interpreted with the foregoing considerations in mind. This work should therefore be of interest to students of metabolism, both research and clinical.

A Practical Handbook of Midwifery and Gynecology for Students and Practitioners. By W. F. T. Haultain, OBE, MC, BA, Gynecologist, Royal Infirmary, Edinburgh; and Clifford Kennedy, MB, ChB, FRCS, Assistant Gynecologist, Royal Infirmary, Edinburgh. Second edition. Cloth. Price \$5.25. Pp 356 with 44 illustrations. Baltimore: William Wood & Company. 1935.

The authors attempt to cover the entire fields of obstetrics and gynecology in outline form. The task is accomplished at the expense of omitting many important details. The chapter on antepartum care is lamentably insufficient but it most likely indicates the authors' lack of appreciation of adequate antepartum care. Whereas the authors recommend that the urine be tested for albumin once a month until the twenty-eighth week and more often after that time, they suggest that blood pressure determinations be made only at each examination except when albumin is found. However, since only three examinations are recommended during the entire gestation (at the first visit and five weeks and two weeks respectively before confinement) only three blood pressure readings are to be made during pregnancy in cases in which albumin is found. Furthermore, no mention is made of weighing patients and taking Wassermann tests or blood counts. It is unfortunate that under the heading of eruptive fevers the authors inadvertently included cardiac disease, diabetes and chronic nephritis. When a cesarean section is necessary in a cardiac case, the authors suggest spinal and chloroform anesthesia, both of which are dangerous for pregnant women. In the prophylactic treatment of preeclamptic toxemia the recommendation is made to examine systematically the urine of all pregnant women during pregnancy but again there is no mention of blood pressure readings. The authors advocate repair of perineal lacerations before expulsion of the placenta. The senior author gets his patients out of bed on the third day after delivery. For uterine inertia during labor, solution of posterior pituitary, a combination of thymus extract and hypophysis extract and estrogenic substance are suggested. In cases of postpartum hemorrhage after expulsion of the pla-

centa the authors first use a hot vaginal douche and if this is unavailing they employ a hot intra-uterine douche. Such douches are usually inefficient and time consuming and permit unnecessary loss of blood. The authors believe that dysmenorrhea caused by acute anteversion of the uterus can be cured by pregnancy. In the section on ovarian tumors, granulosa cell tumors are mentioned but not arrhenoblastoma, Brenner tumor or dysgerminoma. Furthermore, granulosa cell tumors are classified under benign tumors, though a distinct proportion of them are malignant. In the discussion of vaginal discharges no mention is made of monilia infections. The treatment of tuberculosis of the female genitalia is summed up in one sentence: "Spontaneous cure may result by usual tubercular treatment combined with usual local treatments for pyosalpinx." The term "tubercular" endometritis is used instead of "tuberculous" endometritis. In a small book for students and practitioners it is surprising to find a description of the Wertheim operation for carcinoma of the cervix, which is an operation to be performed only by an experienced gynecologist. Throughout the book there are numerous references to proprietary remedies. The book is clearly printed and well written but it is hoped that in future editions, even if no other alterations are made, the chapter on antepartum care will be enlarged, because this subject is of the greatest importance in obstetrics.

Diseases of the Skin. By Frank Crozer Knowles, M.D., Professor of Dermatology, Jefferson Medical College, Philadelphia. Third edition. Cloth. Price \$6.50. Pp 640 with 251 illustrations. Philadelphia: Lea & Febiger. 1935.

A complete revision is presented in this edition. The author has made a sincere attempt to include discussion of the newer items that have appeared in the literature bearing on the various subjects relating to the etiology and diagnosis of diseases of the skin. The work treats most of the cutaneous entities in a concise manner, with excellent reproductions of photographs to illustrate the material in the text. Diagnosis and differential diagnosis is discussed with amplification by differential diagnosis tables. The discussions of the subjects of allergy and allergic skin reactions, eczema, tuberculosis of the skin and tuberculids, and syphilis are worthy of special mention. The book is a good textbook of moderate size and should take its place as such for use by the medical student and as a ready reference book for the general practitioner, although it is not as comprehensive as some of the larger available textbooks.

Osnovy i dostizheniya sovremennoy meditsiny. Periodicheskie sborniki pod redaktsiyey A. A. Bogomoltsa i M. Kogan Yasnogo i D. D. Pleterera. Vol. II [Fundamentals and Achievements of Contemporary Medicine]. Cloth. Price 15 rubles. Pp 340 with 15 illustrations. Kharkov: Meditsinskoe Izdatelstvo U. S. S. R. 1934.

The aim of the publication is to issue periodically a collection of reviews on the more important subjects in medical practice. The function of these reviews is a critical evaluation of the existing knowledge as well as the presentation of the author's own views on the subject. The present volume contains papers on (1) nourishment as a factor in physiology and in pathology, (2) allergies, (3) the problem of edema, (4) functional diagnosis of diseases of the pancreas, (5) diagnosis of obscure and latent forms of malaria, (6) ileus, (7) surgery and irradiation in gynecology, (8) otosclerosis and (9) course of tuberculosis of childhood as gleaned from pathologic anatomy. The articles reflect a broad knowledge combined with a critical attitude. Each is supplemented by an extensive bibliography. They are not accompanied by summaries in a foreign language and for that reason will be available only to those who read Russian.

Food Values at a Glance and How to Plan a Healthy Diet. By Violet G. Plimmer. Cloth. Price \$1.50. 3s. 6d. Pp 120 with 27 illustrations. New York & London: Longmans Green & Co. 1935.

This is an English version of what every housewife, cook or caterer should know about the science of nutrition. The fundamental requirements for the complete healthful diet are not only outlined but explained in a simple and concise manner. The distinctive feature of this booklet is a series of twenty-five colored charts comparing, in a graphic manner, the protein, fat, carbohydrate, mineral, water and vitamin content of the common foodstuffs. These charts, as indicated by the title of the book, offer a rapid means for comparison of food values and should be useful for teaching purposes.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Injuries Attributed to Application of Hair Dye, Idiosyncrasy Not a Defense—Before the incident that gave rise to this suit, the plaintiff's hair was black except for a streak of gray running from front to rear, near the middle of her head. When the incident occurred she was 34 years old and the disfiguring streak had been present since she was very young. To conceal it she had used henna ever since she was 19 years old, except on one occasion. Then, about ten years before the events of this case, she consulted a hair dresser and he put a hair dye of some sort on the discolored area. As a consequence, her scalp "broke out" and she suffered intense itching and was confined to her home for several days. Now, in the hope of finding a method of relief from her disfigurement less time consuming than the henna process, she sought advice at the defendant's beauty shop, in St. Louis. When she sought such advice she explained to the operator to whom she was referred the difficulty she had experienced when she had been treated by a hair dresser before. Then on advice of the operator and on her assurance that the proposed treatment would be perfectly harmless, she submitted to treatment, and the defendant's operator applied a preparation known as "notox." Following this application practically all the plaintiff's hair fell out she suffered certain local and general symptoms of an annoying and serious character, and the new hair that grew in was white. She then instituted this suit. From a judgment in her favor, the defendant appealed to the Supreme Court of Missouri, division 1.

The preparation applied to the plaintiff's scalp, "notox" had been formerly known as "inecto." Two bottles were used in giving a treatment. One of these bottles according to the testimony of a chemist, contained trihydroxybenzene sodium carbonate, saponifiable oil ethyl alcohol and water. The other contained hydrogen peroxide. Any poison that might be in the bottle first described according to the chemist's testimony 'would be overcome by the mixing of the two' and 'there should be no poison resulting from the application of the mixture to the skin.' The manager of the defendant's beauty shop testified that she had known about 3000 persons whose hair had been dyed with 'notox' and that she had known of no one except the plaintiff who had suffered any bad effects as the result of such treatment. The instructions that accompanied the package of "notox" said that 'Notox is safe to use on all normal skins' but added "Persons who are known to have a pronounced idiosyncrasy to skin or scalp diseases or who have at the time any scratch or abrasion to the scalp should apply no form of hair coloring." The physician who attended the plaintiff when she was suffering from the results of the "notox" treatment testified that her whole body was affected but particularly the upper part that she suffered from an acute nephritis with almost complete suppression of urine and from cystitis that her eyes and ears were swollen, the canals in her ears being practically closed that she suffered from arthritis practically all her joints being involved that she suffered intense pain requiring the use of opiates, that it had been necessary to place her on a diet and that she would have to remain on a diet and that her condition was "a hair dye poison," the result of an infection by a poison. This witness thought that the plaintiff's condition indicated permanency.

The defendant contended that the inflammation of the skin from which the plaintiff suffered was a result of an idiosyncrasy which she possessed to substances contained in the dye that her injuries were not caused by anything in the dye that was inherently dangerous or poisonous. A medical witness testified, however, that it could be determined by a simple test whether or not a person was susceptible to a given substance, example, 'take a piece of cotton and saturate it with the material and take another piece without anything

on it and place the two pieces on adhesive tape and put them on the skin and leave it there for a few hours, and if the individual is sensitized to the material, there may appear a red spot where the material was applied."

In the law of negligence, said the Supreme Court, if a reasonable person can, by the use or exercise of ordinary care, foresee the probability of effect of a given cause, it is sufficient to fasten liability, because what one knows and what one should know are equivalent in law. The court quoted with approval from *Gerlin v. Brown & Schler Co.* 177 Mich. 45, 143 N. W. 48, 48 L. R. A. (N. S.) 224, based on injuries alleged to have resulted from the dyed fur collar of a coat.

When the fact is once established and demonstrated by experience that a certain commodity apparently harmless contains concealed dangers and when distributed to the public through the channels of trade and used for the purposes for which it was made and sold is sure to cause suffering to and injure the health of some innocent purchaser even though the percentage of those injured be not large a duty arises to and a responsibility rests upon the manufacturer and dealer with knowledge to the extent at least of warning the ignorant consumer or user of the existence of the hidden danger.

Neither on the basis of the defendant's contention discussed above nor on the basis of any of the defendant's other contentions could the Supreme Court find any ground for reversing the judgment in favor of the plaintiff. That judgment, for \$9,500 was accordingly affirmed—*Arnold v. May Department Stores Co. (Mo.)*, 85 S. W. (2d) 718.

Dental Practice Acts Corporate Practice of Dentistry Illegal in Illinois, Statutory Restrictions on Advertising Upheld—Winberry, a licensed dentist, filed a bill in the superior court, Cook County, Ill. to enjoin certain officials from enforcing the Illinois dental practice act, and New System Dentists, a corporation, intervened in the proceedings. The trial court dismissed the bill and both the plaintiff and the intervenor appealed to the Supreme Court of Illinois. Meanwhile Russell A. Trevillion doing business under the firm name of New System Dentists, had filed a similar bill in the city court of East St. Louis, Ill. That court issued a temporary injunction against the enforcement of the act and the defendants likewise appealed to the Supreme Court of Illinois. The Supreme Court rendered a single opinion with respect to the two appeals.

The Illinois dental practice act imposes certain restrictions on advertising in connection with the practice of dentistry. Among other things, it makes it unlawful to claim superiority over neighboring dentists to advertise free dental services or examinations, or to advertise any amount as a price or a fee. It regulates the type of professional cards that may be used and the size of the name plate that may be displayed on the premises of a dental office. The various complainants challenged the constitutionality of these restrictions, contending that they have no real or substantial relation to the public health. The practice of professions, said the Supreme Court has generally been held to be subject to licensing and to regulation under the police power. Professions are not subject to commercialization or exploitation. In holding that the advertising restrictions contained in the act relate directly to public health and are well calculated to protect it, the court quoted extensively from *Semler v. Oregon State Board of Dental Examiners* 55 S. Ct. 570 (abstr. THE JOURNAL June 1, 1935, p. 2025), in which the Supreme Court of the United States upheld the validity of similar restrictions in the Oregon dental practice act.

The corporate intervenor the New System Dentists, further contended that another section of the dental practice act, which prohibits corporations from practicing dentistry, was invalid. The New System Dentists, according to the evidence had made substantial investments in leases office equipment, electric signs, instruments advertising and advertising contracts prior to the enactment of the section prohibiting the corporate practice of dentistry and claimed that the enforcement of the prohibition would deprive the corporation of its property without due process of law. The corporation further contended that there is nothing detrimental to the public health in the corporate ownership of a dental office so long as all services are performed by licensed dentists. The law answered the Supreme Court is well settled that the state may deny to corporations the right

to practice professions and may insist on the personal obligation of individual practitioners. And this holding has been made regardless of any existing contracts and investments made and entered into by corporations. The act is not to be deemed discriminatory, continued the court, because it denies to corporations the right to operate dental offices and fails to prohibit corporations from operating medical institutes and clinics, drug stores and similar professional establishments. The legislature was not compelled to treat alike all those classes and was not bound to strike at all evils at the same time in the same act, or in the same way. It may deal with the different professions according to the needs of society in relation to each profession.

Accordingly, the Supreme Court held that the challenged provisions of the Illinois dental practice act were valid. It ordered that both bills for injunctions to restrain the enforcement of the dental practice act should be dismissed.—*Wimberry v Hallihan (New System Dentists Intervener) Trowlton v Hallihan (Ill)* 197 N E 552

Workmen's Compensation Acts Silicosis, Period Within Which Claim for Compensation Must be Filed—The workman's employment subjected him to the dust of burnt clay and other vitrified products disseminated by machines used in the manufacture of china, and to silica dust raised by sweeping. In 1927, after several years of employment, he developed a cough. He became chronically tired and weak. The employer discontinued business in November 1933, but at that time the workman did not consider his condition serious enough to require medical attention. The following February a physician diagnosed the workman's condition as due to a slight temporary inflammation of the lungs. In March, when he was treated for injuries sustained in an automobile accident, the physician discovered a tuberculous condition. In May, following roentgen examinations, his condition was diagnosed as pulmonary tuberculosis activated by silicosis. Attributing the silicosis to his former employment, he instituted proceedings for compensation under the California workmen's compensation act. The industrial accident commission dismissed his claim on the grounds that it had not been filed within six months after the date of the injury, as required by the workmen's compensation act. The worker then appealed to the district court of appeal, second district, division 2 California.

In cases of the character under consideration said the district court of appeal, the date of injury, in computing the limitation period set forth in the workmen's compensation act, is not the date of any particular exposure to the hazards of the employment but "the time when the accumulated effects culminate in a disability traceable to the latent disease as the primary cause, and by the exercise of reasonable care and diligence it is discoverable and apparent that a compensable injury was sustained in performance of the duties of the employment." *Maish v Industrial Accident Commission* 217 Calif 338, 18 P (2d) 933. In the case cited, the court disapproved the holding of the commission that the statute of limitations began to run as of the date the employee first was disabled and indicated that the running of the prescription period began when the presence of silicosis was or should have been diagnosed as the primary and efficient cause of the injury. It appears quite obvious, said the court in the present case, that the claimant from the inception of his cough until he received the roentgen report in May 1934, had no reason to believe he was suffering from a compensable injury, silicosis, arising out of his employment. Even his visit to a physician in February 1934 disclosed nothing further than the given diagnosis of a slight inflammation of the lungs from which a speedy recovery was assured.

An employee, continued the district court of appeal, is not to be deprived of compensation because he incorrectly diagnoses his condition. The commission in this case found that the claimant should have discovered the character of his condition prior to the date of his final termination of work. Such a finding, concluded the district court of appeal is without support in the evidence. It is wholly unreasonable to argue that the worker should, through the exercise of reasonable care and diligence, have known in November 1933 that which his medical adviser did not discover in February 1934. The court accordingly ordered that the award of the commission

dismissing the claimant's claim be set aside and that the commission proceed with the determination of the claim.—*Price v Industrial Accident Commission of California (Calif)*, 49 P (2d) 294

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1926 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Lung Puncture in Lobar Pneumonia—Sappington and Favorite performed diagnostic lung puncture in sixty cases of lobar pneumonia (fifty-seven pneumococcal and three streptococcal). Positive cultures, suitable for typing, were obtained in 90 per cent, half of these within six hours. Lung puncture cultures made three and twenty-four hours after the administration of antipneumococcus serum were positive. In twenty-five cases in which both the lung and sputum pneumococcus were typed, there was 100 per cent agreement. When sputum is at once available, therefore, lung puncture is unnecessary. In twenty two of the cases, however, the sputum was either absent or unobtainable at the time the lung puncture was made. The method is therefore recommended for early diagnosis and typing when sputum is not as quickly available. In the technique detailed, the use of a single tube of blood agar with 15 cc of plain broth at the bottom of the tube is so simple and adequate that the authors recommend it. The very rapid growth of the lung organisms in this small amount of broth with the few drops of lung blood or exudate allows early typing of the pneumococcus and usually the recognition of the type of streptococcus.

Association of Erythremia and Duodenal Ulcer—Kraemer and Asher have recently observed two patients having associated erythremia and duodenal ulcer. Both patients were Russian Jews employed in tailoring establishments. The gastrointestinal complaint was predominant in both. The first patient presented nothing of unusual interest and is offered merely because it adds another case to those already reported of the association of the two diseases. The second patient was more cooperative. A series of lavages was attempted not only to relieve the ulcer symptoms but also in the hope that the erythremia might improve as it did in the case treated by Morris and his associates. When the patient was cured of his painful ulcer symptoms and since he knew that his red blood cells were not being reduced, he was no longer content to continue

the lavages. Treatment was discontinued in March 1934. A follow up in May 1934 revealed that the patient was still free from his ulcer symptoms and was receiving roentgen therapy for his erythremia. Apparently not all cases of erythremia are benefited by lavaging addison from the stomach. The authors believe that it is possible that they did not carry out frequent enough washings. Should a patient with erythremia and duodenal ulcer show a marked reduction in the erythrocyte count after gastric lavage gastrectomy might afford permanent cure of both disorders. This operation would remove the source of addison and at the same time cure the ulcer.

Creatinuria in Adult Males—Taylor and Chew found creatine in the urine of fifteen adult men in amounts varying between 0 and 196 mg of creatine nitrogen in twenty-four hours. This amount of creatine was not materially changed by marked restriction of the protein intake. The authors present some data suggesting that unusual muscular activity or sudden change in muscular activity may result in an increase of the creatine excreted.

Spontaneous Hemopneumothorax—In analyzing the cases reported in the literature and their own case, Jones and Gilbert were impressed by the great similarity between the etiology of idiopathic pneumothorax and hemopneumothorax. The factors

seem to be the same so far as the rupture of the lung and the escape of the air into the pleural cavity are concerned whereas the accompanying hemorrhage can be explained only on the basis of chance. When an emphysematous bleb ruptures because of increased intrapulmonary or intrathoracic pressure or by external forces, the usual occurrence is the escape of air into the pleural cavity. If in the course of this rupture a blood vessel is torn in the wall of the bleb or in the attached pleural adhesion, the escape of air is accompanied by a hemorrhage, the amount of which is determined by the size of the involved vessel and also by the various intrathoracic reactions resulting from the outpouring of air and blood into the pleural cavity. The case reported by Palmer and Taft demonstrates the part which chance plays in causing either a pneumothorax or a hemopneumothorax. Treatment in cases of mild hemorrhage should be conservative, whereas patients suffering from larger hemorrhages should have the blood removed from the pleural cavity and air replaced. In some of the latter cases surgical methods may be used following the removal of blood. Prognosis in most cases is good but depends on the amount of the pleural hemorrhage.

Hemorrhagic Pleurisy of Tuberculous Origin and Hemopneumothorax—Korol points out that the hypothesis that tuberculous hemorrhagic pleurisy is caused by bleeding intrapleural granulations is no longer tenable. Hemorrhagic pleurisy is not an inflammatory condition but a hemorrhage associated with a spontaneous pneumothorax. The pneumothorax occurs first and is caused by the rupture of an emphysematous vesicle. The hemorrhage happens if there are coexistent localized adhesions preventing the complete retraction of the lung, the weight of the noncollapsed lung may tug on the adhesion and tear it. The hemorrhage then takes place from the distal stump of the adhesion. In certain cases of artificial pneumothorax the hemorrhage may be produced by the tuberculous process spreading in all directions in the treated lung, there may occur an erosion of a large blood vessel and simultaneous perforation into the pneumothorax cavity. In hemorrhagic pleurisy, as in traumatic hemopneumothorax there is the escape of all the hematologic elements from a severed blood vessel into the pleural cavity. The blood coagulates immediately before all the cells have become enmeshed. The pleural fluid contains numerous red cells but no fibrinogen and for that reason looks like blood but remains liquid on standing. In the cases of hemorrhagic pleurisy reported since 1900 the associated pneumothorax was generally recognized. Prior to the roentgen era the pneumothorax was often overlooked. The pleural adhesions and the partly functioning upper lobe produced bizarre physical conditions, rendering diagnosis difficult or impossible. However, in the majority of case reports containing detailed clinical or postmortem data the coexisting pneumothorax is strongly indicated.

Tuberculin-Positive Children Observed for Various Periods Up to Five Years—During the last three months of 1934, which marked the close of a five-year period, Weintraub made a survey of the 1,041 clinic children who had been 15 years of age or less at the time they were found to show a positive tuberculin reaction to 1 mg of old tuberculin. These children had roentgenograms taken at the time their tuberculin sensitivity was discovered and have been under observation for periods varying from six months to five years, with refilming in those cases in which it appeared most desirable after considering all existing circumstances, and in the end governed by the willingness of the patient to cooperate. The roentgenograms were read from the standpoint of showing the adult type of pulmonary tuberculosis or any evidences of the childhood type of tuberculosis. Physical examination of the chest was not found to be of any value in either the diagnosis or the follow up of children with childhood type lesions, since even the pneumonic parenchymal lesions of the primary type usually yielded no identifying physical signs. With the appearance of the adult type of involvement positive signs may be elicited, but even then as a rule only after considerable progression has occurred. The early lesions are found only by means of the roentgenogram and should be discovered before symptoms have appeared. The study comprised 508 males and 533 females. There were 542 contacts and 499 noncontacts. In the male group there were 254 contacts and 254 noncon-

tacts, and in the female group 288 contacts and 245 noncontacts. There were 639 children who were under observation for periods of more than three years and only 224 who were observed for periods of less than two years. In the male group, 50 per cent were contacts, 26 per cent showed roentgen evidence of childhood type involvement alone, while 10.6 per cent of the noncontacts showed similar involvement. In the female group, 54 per cent were contacts, 24 per cent showed roentgen evidence of childhood type involvement alone, with similar conditions in 12 per cent of the noncontacts. With respect to childhood type lesions, as demonstrated roentgenologically by the usual procedure, there was no significant variation according to sex. With respect to adult type pulmonary tuberculosis an entirely different picture is presented. Six cases were found in the final roentgen examination of these 1,041 children, however, during the course of the study previous to the final survey, five children had been found who had developed the adult type of disease as shown by the roentgenogram, after they had previously been under observation and yielded a positive tuberculin test and a roentgenogram negative for the adult type of pulmonary tuberculosis.

Bilateral Trigeminal Tic—Harris has records of forty one cases of chronic spastic paraplegia complicated by trigeminal tic. In seven there was bilateral trigeminal tic. Very rarely did the neuralgia commence before organic signs of spinal cord disease appeared. In addition to these, in one family the father had trigeminal tic and his daughter developed typical disseminated sclerosis, and in another family the mother had neuralgia and her son developed disseminated sclerosis. In another the aunt was treated for typical bilateral tic and her

niece for trigeminal tic complicating disseminated sclerosis. The author has seen in many instances familial heredity of typical trigeminal tic, in one family no less than nine members appeared to have suffered from it.

Unusual Inflammatory Lesions of Ileocecal Region—Powers calls attention, by the use of three clinical reports, to the interrelationship of inflammatory lesions of the terminal ileum, appendix, cecum and ileocecal lymph nodes. The first patient had diffuse inflammation of the terminal ileum, appendix and cecum and secondary involvement of the ileocolic nodes in the mesentery, in the second case the tip of an inflamed appendix was adherent to a mass of enlarged mesenteric nodes, the third case was one of primary typhlitis with localized ulcerative, inflammatory changes in the wall of the cecum. Regional ileitis, acute nonspecific inflammation of the cecum and mesenteric lymphadenitis in the ileocolic angle are discussed. In view of (1) the similarity between the lymphatic apparatus of the appendix and terminal ileum, (2) the frequency of mesenteric adenitis as an accompaniment of regional ileitis and (3) the lack of interest in the ileocolic nodes in the presence of obvious appendicitis, it is quite possible that these nodes are involved more frequently than is generally suspected. The author believes that the prompt subsidence of symptoms following appendectomy in Wilensky's early cases, in the cases reported by Rocky and in his first two cases, and the anatomic relationship of the lymphatic channels of the appendix to the ileocecal lymph nodes suggest that the appendix does play some part in the etiology of this form of glandular inflammation.

Further Observations on Tumor of Pineal Body—Horrax adds two cases of tumor of the pineal body to the literature. In one, in an adult, the growth was partially removed and verified at operation. Subsequent to operation and roentgen therapy the patient had remained well and in active life for one and one-half years with no return of symptoms of intracranial disturbance. In the second case, in a boy 10 years of age, the tumor was verified only by ventriculography. The child presented the typical syndrome of Pellizzi: macrogenitosomia praecox. This patient also had had a period of normal activity for a year following decompression and roentgen therapy. After roentgen therapy he became more normally youthful in appearance. This is at least suggestive of some possible function of the pineal body concerned with the regulation of secondary sex characteristics.

Electromyographic Study of Myotonia—Lindsley and Curnen describe a case of congenital myotonia and a case of myotonic dystrophy. The myotonia, which appeared to be the same in the two cases, was studied electromyographically. The after contraction of myotonic muscles, which persists after the cessation of voluntary effort or brief mechanical stimulation, is accompanied by action currents. This indicates that the phenomenon is neurogenic rather than myogenic. The evidence presented favors the hypothesis that the after-contraction of myotonia is of reflex origin and is due to the persistent discharge of hyperexcitable sensory end organs in the muscle.

Injections of ergotamine tartrate, pilocarpine hydrochloride and epinephrine hydrochloride have proved ineffective in relieving the myotonic condition although calcium gluconate and calcium chloride have significantly reduced the amount and duration of the after contraction.

Peripheral Venous Blood Pressure in Schizophrenic and in Normal Subjects—Krinsky and Gottlieb obtained venous blood pressure values by the direct method under basal as well as nonbasal conditions for fifty schizophrenic patients and twenty-five normal subjects. The mean pressure for patients and normal controls under both basal and nonbasal conditions was 11 cm of blood. The mean individual variation of the peripheral venous pressure was less in schizophrenic patients than in normal subjects. Under basal conditions the schizophrenic patient showed an average standard deviation of 0.83 cm while the normal control showed an average standard deviation of 1.45 cm. Under nonbasal conditions the values were 0.92 and 1.94 cm respectively. The peripheral venous pressure did not vary in accordance with the arterial blood pressure. No significant relationship was indicated between the degree of peripheral cyanosis and the level of the venous blood pressure.

Malaria in Control of Atrophy of Optic Nerve—Clark reports twelve cases in each of which syphilis of the central nervous system was present with syphilitic invasion of the optic nerve and visual pathways. There were eight patients with tabes and two each with dementia paralytica and dementia paralytica of the tabetic form. The condition of eight patients improved under therapy. One of the eight patients was treated by injection of typhoid vaccine intravenously because she was resistant to the strain of the organism of tertian malaria used, the other seven were treated with induced malaria. There was no improvement in four of the patients, and the ocular condition continued to progress until blindness resulted. This was to be expected owing to the advanced state of atrophy of the optic nerve that was present before treatment with malaria was started. The state of the pupils was unchanged in all twelve patients. If invasion of the optic nerves and visual pathways has taken place, it is prudent to treat the patient as early as possible with malaria. Malaria does not possess magic power to restore function to an optic nerve with advanced atrophy of the tissue but induced early it enables the natural barriers to syphilis to be established before vital tissue has lost its function. The optic nerves chiasma and optic tracts are involved by the same meningeal infiltration that is largely responsible for the damage of syphilis to other structures. When this infiltration is arrested before maximal damage has occurred, the decline of vision is halted and the patient is saved from blindness. Additional factors probably play a minor part in the defense developed against the spirochete after malaria vasodilatation and increased metabolism. For some patients there is a mild hyperemia of the optic disks during the paroxysm of malaria. The factors of fever, vasodilatation, increased body metabolism and stimulation of the reticulo endothelial system appear to be the means by which malaria and other acute febrile diseases offer to the body an effective defense against syphilis of the central nervous system.

Experimental Encephalography with Anesthetic Gases

—It occurred to Aird that an anesthetic gas might qualify as the desired agent in encephalography. Since only a limited amount of gas can be injected and since this is relatively inert except as absorbed, it seemed conceivable that even strong anesthetic gases might prove safe, any sedative or narcotic effect being the result of its absorption and concentration in the central nervous system. Also the local effect of such a gas on the nerve tissues with which it was in direct contact might be to deaden them and abolish noxious reflexes, in contrast to the effect of ordinary gases. The duration of its presence would depend on such factors as its rate of diffusion and solubility in the spinal fluid and in the lipoids. The investigation of such a possibility seemed worth while. A state of light anesthesia induced by sodium amytal finally proved satisfactory. The dose necessary varied with the animal, but amounts from 22 to 32 mg per kilogram of body weight were found satisfactory. With such doses the animal was quiet, good roentgenograms could be obtained easily, the injection of procaine hydrochloride and puncture of the meninges aroused the animal only briefly, and yet reflexes, muscle tension and often a fair degree of consciousness remained, so that superimposed irritative or narcotic effects of the injected gases usually could be determined readily. The usual routine of encephalography was as follows. After the intravenous administration of sodium amytal and the making of an initial plate of the skull as a control, the dog was strapped on its side to the table, and with aseptic technique and with local anesthesia a lumbar puncture was performed. The table was elevated, and intermittently between collections of spinal fluid the gas to be tested was injected slowly, by means of a syringe, into the subarachnoid spaces. Rotation of the head aided drainage. A three-way petcock attached to the injecting syringe and connected by tubing to the controlling valve of the gas tank afforded a simple and convenient closed system for handling the gases. Replacement of the spinal fluid by gas was carried as far as possible usually until bubbles returned through the needle. Then the needle was withdrawn, and another lateral roentgen view of the skull was made. If the ventricular outline appeared other views were taken to follow the course of the injection. Throughout the entire procedure pulse, respiration, color, reflexes and muscle tension were observed closely and recorded. With improvements in technique standardization of routine and experience, this method proved satisfactory for determining the following information on the various anesthetic gases: (1) ease of handling, (2) early irritative effect, (3) sedative or narcotic effect, (4) after-effects, both immediate and late, (5) safety, and (6) roentgen results including the time of absorption. Ethyl chloride, divinyl chloride, ether, vinyl chloride and acetone proved unsatisfactory for encephalographic use, the first three being decidedly dangerous. In limited series the effects of oxygen and those of cyclopropane appeared to be comparable to each other and definitely superior to those of air. Because of their safety, good roentgenographic results, minimal irritation, definite sedative effect and lack of ill effects, either clinically or pathologically, nitrous oxide and ethylene seem ideal agents for encephalography.

Posttraumatic Acute Bone Atrophy—According to Gurd the results of treatment appear to prove that the process of acute bone atrophy is reversible, the length of time required to bring about clinical cure is likely to be prolonged for from six months to an even longer period. With reference to treatment, the most important memorandum is that pain should be avoided and, more particularly, that anything in the nature of forcible manipulation, either with or without an anesthetic, should be excluded. In the case of the upper extremity, if further insult to the tissues is avoided the course is toward repair. The patient should be warned that no painful movements of any sort should be undertaken. Both snugly fitting unpadded plaster casts and physical therapeutic measures may be employed especially diathermy with hot bathing at home. The latter procedure as a rule, pleases the patient better and also is followed by rather better results. In the case of the lower extremity, the unpadded walking plaster cast, which is applied after absolutely all interstitial edema has been disposed of and to which a felt heel has been added, is the method of choice. If care is applied to remodel the foot, particularly with reference to overcoming pronation and flattening of both arches and if the patient walks sufficiently, the results are satisfactory. Sympathectomy as recommended by Fontaine and Herrmann has been carried out in one case. The result was not favorable, but the evidence which these authors supply cannot be ignored.

Surgical Treatment of Chronic Ulcerative Colitis—During the last four years Kunath treated eighteen patients for chronic ulcerative colitis by the establishment of an appendicostomy or a cecostomy, with subsequent irrigation of the diseased intestine through a tube. A series of thirty-five cases of chronic ulcerative colitis has been surveyed to evaluate, if possible, the relative merits of the various operative procedures used. He has found appendicostomy and cecostomy with subsequent irrigation of the diseased intestine a useful procedure in selected cases. The study emphasizes the limitations of all forms of surgical treatment and the apparent futility of expecting cures from any procedure less than colectomy. The author feels that any blanket form of therapy, i. e., one operative procedure used on all types of patients as they come, cannot give the best results. By carefully analyzing each case, by using certain limitations of each type of operation the present results can be improved to an appreciable degree. A simple classification of cases has been suggested, which may point the way toward more intelligent treatment. This outline of treatment represents only a transient opinion rather than a permanent policy. There is no ideal method of treatment, and one is usually faced with the problem of choosing the least vicious of several evils. However, surgery has something definite to offer these patients, and the problem involves the choosing from a number of procedures at one's disposal the one most suited to each case.

- Clinical Experiences with Wheat Germ Oil (Vitamin E)**—Watson prescribed wheat germ oil to sixty-five patients respecting whom spontaneous abortions, threatened

abortions or involuntary sterility constituted the principal abnormalities. The patients have been classified into four groups: group 1, pregnant women who had experienced two or more spontaneous abortions previous to receiving wheat germ oil treatment (habitual abortion), group 2, pregnant women who had experienced one spontaneous abortion previous to receiving wheat germ oil treatment, group 3, cases of threatened abortion, and group 4, women who sought medical advice because of failure to become pregnant (sterility group). The patients included in groups 1 and 2, with but two exceptions, were pregnant at the time the treatment with wheat germ oil was started. The purpose of the treatment was to favor the continuation of the pregnancies. The patients in group 3 received the oil only after the onset of the symptoms of threatened abortion, and its administration was a part of the treatment for that condition. Those in group 4 were not pregnant at the time the oil was used, although several had been pregnant previously. The object of the treatment in these cases was to facilitate impregnation. In the majority of the abortion and sterility cases no therapeutic measures except the use of wheat germ oil were instituted. But the patients with signs of threatened abortion were subjected to the usual management for that condition and received wheat germ oil. Of eleven patients who had sustained from three to fifteen spontaneous abortions prior to the exhibition of wheat germ oil, nine went to term and were delivered of healthy living children. Six of the patients under this regimen completed a pregnancy for the first time. Of the seventeen wheat germ oil treated patients, each of whom had had two spontaneous abortions, twelve gave birth to healthy living children after the use of the oil. In five cases the pregnancies were interrupted by spontaneously occurring abortions. Of nine treated patients, each of whom had experienced one previous spontaneous abortion, eight gave birth to healthy, living children. In the ninth one abortion took place a short time after the use of the oil was commenced. Fifteen patients were treated for the symptoms of threatened abortion, the majority after bleeding had begun. In eleven of these the pregnancies continued uninterruptedly to terminate in natural deliveries but in four instances the abortions became inevitable. Thirteen non-pregnant women were given wheat germ oil with a view to facilitating impregnation. Six of these had never conceived and therefore constituted examples of primary sterility. Each of the remainder had been pregnant at least once, which placed them in the category of so-called secondary sterility. Seven had had one or more abortions, but only one woman had given birth to a living child. Pregnancy did not ensue in any of the patients in this group. Conception occurred in two of Vogt-Moller's four sterility cases and living babies were delivered. The experiments lend some support to the surmise that vitamin E is a factor in the advancement of pregnancy to a natural termination.

Hemoglobin of Normal Children and Certain Factors Influencing Its Formation—Ross and Summerfeldt determined the hemoglobin content of four groups of normal children by the Newcomer method. The first group consisted of seventy-seven boys from 11 to 14 years of age from business and professional homes, who were day pupils attending a private school. In the second group there were 151 boys and girls from 5 to 14 years of age. These children were from average homes of the working class. The third group comprised thirty boys from 10 to 14 years of age who were living in an institution in the city, and the fourth group consisted of seventy-two boys and girls from 5 to 14 years of age who were living in an orphanage in the country. It was found that the hemoglobin content of the blood of normal children is lower than the accepted adult standards and varies with the age and economic status of the child. The addition of an iron free and copper free vitamin B complex concentrate to a diet considered adequate according to the present dietary standards resulted in a moderate increase in the hemoglobin content of the blood of normal children. The substitution of a cereal mixture rich in iron and copper containing vitamin B complex for the ordinary cereals contained in a diet considered adequate according to the present dietary standards resulted in a marked increase in the hemoglobin content of the blood of normal children. A further increase in the iron content of this special cereal mixture bringing the children's daily intake of iron to 36 mg. produced a still further

increase in the hemoglobin content of the blood. The optimal iron intake for hemoglobin formation in normal children is greater than the present accepted standards.

Postanesthetic Leukocytosis—Boyd ascertained the lipid composition of the white blood cells immediately before and again at an interval of from one-half to twenty hours after anesthesia in a group of noninfected patients submitted to various surgical procedures involving a relatively small loss of blood. The type of operation was not found to affect the results. The anesthetic was either following induction by chloroform or nitrous oxide. Morphine and atropine were given before operation. The white cells were separated from samples of about 50 cc of blood, ground with cleaned sand and extracted with alcohol-ether. The resulting extracts were analyzed by the Bloor oxidative micro methods as modified by Boyd. It was found that the phospholipid content of blood leukocytes was lowered by anesthesia, the most marked decrease occurring after the third hour after operation. The percentage of free cholesterol exhibited minor inconstant changes. When the concentration of neutral fat was high before operation it became lowered after, and, conversely when low before it became increased after anesthesia. The changes for cholesterol esters were similar to those for neutral fat, the direction of the effect of anesthesia depending on the initial concentration of this lipid. From these studies it is concluded that the polymorphonuclear leukocytes mobilized into the circulating blood after anesthesia contain decreased amounts of phospholipid, about the same percentage of free cholesterol and a medium value for cholesterol esters and neutral fat, as compared with the leukocytes present before anesthesia. The leukocytosis of anesthesia, therefore, differs chemically from the leukocytosis of fever and infection. A review of the literature revealed that there is a species variation among animals in the effect of anesthesia on the white cell count.

Pyelitis and Cystic Ureteritis—Hinman and his associates describe cases which show that cystic disease of the ureter and renal pelvis may be associated with ureteral obstruction and infection calculi carcinoma and bilateral infestation and possibly with the elimination of toxic substances through the urinary tract. The gross pathologic changes may be described briefly as cystic structures varying from microscopic to several centimeters, from spherical to ovoid, and from embedded to pedunculated. They vary from clear to whitish yellow brown gray, bluish or hemorrhagic. The contents may be thin and watery or thick, viscid and colloidal. As to pathogenesis four hypotheses are advanced (1) the occlusion of crypts in the mucous membrane, with retention of the secretions of its epithelium, (2) the pathologic blocking and secretion of glands already present in the urinary passages, (3) psorospermial infestation and (4) the "cell nest theory of von Brunn. Most of the evidence is in favor of von Brunn's theory. A chronic inflammation of the mucous membrane produces downward proliferation of the surface epithelium. These downgrowing buds become pinched off and form epithelial cell nests in the submucosa. These in turn proliferate their centers degenerate and they push upward toward the lumen of the urinary tract as cystic structures. A history of chronic infection of the urinary tract associated with hematuria should suggest it and cystic cystitis almost always is found by cystoscopy. The diagnosis is made by ureteropyelography. The pyelogram may show two types of filling defects, one of the pelvis the other of the calices. The ureterogram shows a characteristic mottling caused by nonopaque filling defects in the outline of the ureter. Other pathologic conditions that might be confused with this picture are those affecting the pelvis—early polycystic kidney and chronic pyelonephritis—and those affecting the ureter—non-opaque stones blood clots multiple papillomas or bubbles of air. The first step to be taken in the treatment of this condition

is obviously the removal of the source or cause of the inflammatory process. The passage of large ureteral catheters and irrigation with silver nitrate solution, as suggested by Kindall and practiced by the authors with some measure of success, would seem to be the conservative course. The relief of obstruction, when present, is the first consideration. Pyelotomy, ureterotomy or even nephrectomy may be indicated when the disease is unilateral and advanced to the point of renal insufficiency which has not responded to conservative measures.

Some Observations on Female Urology—Stevens cites a number of cases that illustrate the similarity in symptomatology often existing in pathologic conditions of the female urinary and generative organs and emphasize the importance of examination of the uterus and adnexa as well as the urinary tract in most instances. Pain and other symptoms associated with ectopic kidneys are sometimes suggestive of lesions of the female generative organs and pyelography will frequently reveal unsuspected pathologic changes. Both cystography and cystoscopy are of value in the diagnosis of bladder displacements and deformities following childbirth and pelvic surgery. Urethral strictures are common in women. The majority are located at the external meatus and may be congenital or acquired. They are frequently responsible for pathologic changes in the upper part of the urinary tract and for a large variety of subjective symptoms, including pain in various locations. The early detection and correction of strictures and other conditions responsible for obstruction of the female urethra is obviously of great importance. The average size of the normal urethra in the adult female is F 26. The average size of urethral strictures is F 21.5. Urethrography is a valuable diagnostic procedure. It is frequently indicated in the presence of symptoms suggestive of pathologic changes in the urinary tract in women. Lesions of the urethra play an important part in female urology.

Question of "Influenza" and Atypical Pneumonia—

Cass observed a group of fifty-three cases, each of which it was felt justifiable to call "influenza" (Francis). These patients all recovered and the only points of interest were that six developed mild pansinusitis with symptoms of this complication for a duration of from four to seven days. These cases all responded to medical treatment. Two other patients developed acute otitis media, both unilateral, and both required paracentesis. The second group consisted of seventeen cases in which, in addition to the clinical picture of influenza, definite signs of involvement of the chest were present and the active course of the disease extended over a period of from five to sixteen days. The third group consisted of two cases, both fatal, in which hemolytic streptococcus empyema developed. In addition to the symptoms considered necessary for diagnosis, all patients complained early of vague abdominal distress with marked distention and anorexia. The principal complaint in addition to prostration was a cough, this being harsh, dry, nonproductive and coming in paroxysms. Paroxysms were particularly frequent during the latter part of the afternoon and during the night. They were also brought on at any time by movement or physical effort on the part of the patient, or marked change in temperature of the room. The patients with involvement of the chest were subject to alarming waves of cyanosis, in addition to the constant appearance of extreme toxicity. The two patients with empyema complained of a severe pleural type of pain. The temperature was of the septic type and varied only in degree and duration in the different groups. The temperature returned to normal in all cases by lysis. The pulse, characteristically, was not so high as one would expect in all except the fatal cases. The typical case of influenza is so similar to what is commonly called "grip" that the diagnosis is probably not made unless there is a recognized epidemic present. The complications of the typical cases are usually infections of the sinuses and ears. These seldom require surgical treatment other than paracentesis of the ear. The cases of pulmonary involvement included in this material were strikingly similar. Many other pneumonias were seen with white blood counts of from 6 to 20 thousand and were not proved pneumococcal pneumonias but the clinical pictures were so different one from the other that no consistent material could be obtained from them. With the present available data, it is impossible for the author to state that the cases classified as group II were not simply complications of influenza. However, their clinical pictures were so strikingly similar and hemolytic streptococci were so commonly found associated with the disease that it is difficult

for him to classify them other than as a specific type of pneumonia. They were not seen during the height of a severe influenza epidemic and their similarity thus conforms to the proper time element. The two fatal cases definitely terminated with a hemolytic streptococcus empyema or pleurisy, and undoubtedly also a septicemia.

Acute Demyelinating Disseminated Encephalomyelitis—Ferraro and Jervis report a case of acute demyelinating encephalomyelitis characterized pathologically by (1) two large diffuse symmetrical foci of demyelination in the medullary substance of the cerebral hemispheres comparable to the foci described in diffuse sclerosis, (2) several areas of concentric demyelination, i e, comparable to the one described in the so-called concentric sclerosis and (3) numerous small patches of demyelination scattered throughout the cerebral hemisphere, the basal ganglia, the pons and the medulla oblongata and comparable to the ones described in acute multiple sclerosis. The authors stress the importance of the association in their case of clinical and pathologic features of diffuse sclerosis, concentric sclerosis, acute multiple sclerosis and disseminated encephalomyelitis. A brief account of the opinions of various authors as to the relationship of these conditions is given and the belief is expressed that diffuse sclerosis, concentric sclerosis, acute multiple sclerosis and disseminated encephalomyelitis might constitute a large nosologic group with identical underlying clinical and pathologic observations. The question whether the same etiologic factors are at the base of the various conditions mentioned is not ready for solution. Some experimental data, however, point to the fact that in the nervous system different etiologic factors may produce pathologic changes common to acute encephalomyelitis, multiple sclerosis and diffuse sclerosis.

Massive Onlay Bone Grafts—West warns that the following points should be considered in performing massive onlay of bone grafts in cases of nonunion of fractures of the upper limbs 1 It is not a simple procedure and trained assistants are considered necessary in order that the operation be done efficiently and in as little time as possible 2 There is danger of tourniquet paralysis in major bone operations of the arm Therefore the tourniquet is dispensed with 3 In repairing fractures of the lower part of the humerus radial nerve injuries are not unusual, but wrist drop following the operation should not be a cause of anxiety, provided the surgeon is certain that there has been no division of the nerve Retraction, which is necessary, quite often causes sufficient pressure to cause temporary loss of radial nerve function 4 Bone grafts for nonunion in infected compound fractures should not be done until one year has elapsed from the time of cessation of drainage 5 The condition of the skin should be perfect in the region of the fracture and in that part of the leg from which the graft is removed and it is not feasible to operate through heavy adherent scars 6 In cases in which metal plates, beef bone or ivory plates have been used unsuccessfully and have resulted in bone atrophy, it is better to remove them as a preliminary operation to a second or major graft operation 7 In cases of fracture of the upper humerus, the upper end of the graft should be driven up into the head, thus making a secure anchorage The lower end of the graft can be maintained because cortical bone is usually sufficiently solid 8 The operation for the bone grafting of the two bones of the forearm at the same time is a formidable procedure Therefore, if it is at all possible, conservative treatment should be used until at least beginning union is observed in one bone An onlay graft fixation of one bone tends to splint the forearm to a degree that union will be obtained in both bones In case nonunion persists in the unoperated bone a second bone graft operation may be done But, to do grafts on the two bones at the same time calls for smaller grafts or the necessity of removing the grafts from the two legs at the same time

Thymus Syndrome in the New-Born—Graham discusses his observations in children from 6 days to 6 months of age who presented the thymus syndrome Besides the symptoms of cyanosis, stridor, suffocative attacks and dyspnea usually referred to four other symptoms were observed Five of the seven infants were blue babies at birth A rather large percentage of babies are blue at birth owing to various causes The thymus baby is usually among them A poor gain in weight or an actual loss was observed in four cases The more severe the disease, the more pronounced is the loss of weight And any gain in weight may be quite fickle Mucus in the vomitus and feces especially the latter, was present in three cases Cervical retraction was present in three of the seven cases, and in one case a tentative diagnosis of meningitis had been made Capper and Schless make the statement, with which the author concurs, that before a diagnosis of thymus syndrome can be made one must differentiate and exclude atelectasis

cerebral hemorrhage congenital heart disease, laryngeal anomalies or infections, bronchitis or pneumonia, hypertrophied mediastinal glands, retropharyngeal, peritonsillar or cervical abscess, asthma, laryngospasm or tetany of the new-born congenital laryngeal stridor, micrognathia, large adenoids, breath holding, macroglossia, tongue swallowing and foreign body in the pharynx or larynx Roentgen irradiation was the only treatment that the author used in his cases The number of treatments ranged from one to six The size of the gland as shown roentgenographically does not necessarily indicate the severity of symptoms Simple hyperplasia or lateral enlargement of the thymus gland should not be diagnosed as thymus disease on the basis of roentgen observations alone, but it should be carefully observed and certainly so diagnosed when symptoms appear And, conversely, in the presence of thymic symptoms and absence of positive roentgen observations he feels that immediate and adequate roentgen therapy should never be denied any child

Sterility from the Standpoint of the Female—Rucker states that 36 per cent of patients with primary sterility and 65 per cent of those with secondary sterility (primary, in which the patient has never conceived, and secondary, in which the patient has been pregnant at least once, even if it was only an abortion) became pregnant when treated for cervicitis. Posture and pessary treatment gave 16 per cent positive results in primary sterility and 64 per cent in secondary sterility. In the primary group 26 per cent of the patients with patent tubes and 48 per cent of the patients in the secondary group became pregnant soon after this test. Half of the patients in the primary group with partially closed tubes and 20 per cent of those in the secondary group became pregnant. Of the primary sterility patients with closed tubes 15 per cent and 33 per cent of the secondary patients became pregnant. All secondary sterility patients and 21 per cent of the primary sterility patients became pregnant on thyroid medication when such treatment was indicated either from the history or because of a minus metabolic rate. The primary group yields a total of 38 per cent of pregnant cases and the secondary group 52 per cent. It would seem then, that cases of secondary sterility are more amenable to treatment by ordinary gynecologic methods than the primary cases. Conversely, more of the cases of primary sterility have a deeper fundamental endocrine developmental or congenital basis.

Peripheral Nerves and Subacute Combined Degeneration of Cord—Greenfield and Carmichael obtained peripheral nerves from cases of subacute combined degeneration. The myelin sheaths were stained by placing the nerves in a 1 per cent solution of osmic acid for from twenty-four to thirty-six hours immediately after they were removed from the body. The authors accept the great difference in measurements as well as in counts of myelin sheaths in the nerves of cases of subacute combined degeneration of the cord from those found in normal nerves as evidence that there is a true degeneration of the peripheral nerves in this disease. Except in the rapidly fatal case of subacute combined degeneration of the cord, there was very little abnormality in the contour of the myelin sheaths as seen in longitudinal sections, and nothing was ever seen suggesting wallerian degeneration. On the other hand, the preponderance of myelin sheaths of small size, as well as the poor staining of many of the myelin sheaths as compared with those in normal nerves, suggests that in subacute combined degeneration the nerve fibers suffer a general impoverishment of myelin. No doubt wallerian degeneration of individual fibers may occur in severe and rapidly progressive cases, but this must be exceptional. The appearance in the osmic acid sections might be interpreted as indicating edema of the fine nerve bundles. That edema of nerve does occur is known and it is the rule in many forms of polyneuritis. The presence of edema in the nerves in cases of subacute combined degeneration, if established, would therefore confirm rather than disprove the view that lesions of peripheral nerves are present in this disease. However, no definite evidence of edema was found in celloidin sections of the peripheral nerves in any case of this series, although the Weigert-Pal sections of these nerves gave evidence of considerable loss of myelin sheaths. Therefore it is not possible to explain these results on the basis of edema of the peripheral nerves.

Carcinoma of Colon—Devine bases his method of operating on the distal colon for carcinoma on the principle that if in an animal a segment of intestine is experimentally isolated and thus deprived of its function, its bacterial content will slowly

disappear. The proximal colon is disconnected completely and permanently from the distal colon, at the transverse colon if mobile enough or at the hepatic flexure. Completeness and permanence is ensured by inserting the cut ends of the intestine into small separate openings in the abdominal wall. No feces can pass into and infect the isolated segment. Time, then, becomes a factor in bringing about a 'debacterIALIZATION.' After this disconnection the distal colon is completely 'defunctioned.' Its contents can now be washed out, and, with the process of time and antiseptic preparations its bacterial contents become reduced to a minimum. In this defunctioned distal colon, which is quiescent, retracted and clean, it is possible to perform safely an orthodox sutured anastomosis. This is still possible even if the segments of intestine in question are incompletely peritonealized and even if there is great disparity in their caliber. In the case of carcinoma of the upper and lower parts of the sigmoid the requisite amount of intestine that should be removed with the carcinoma and the proper amount of pertaining mesenteric leaf, can be critically estimated and removed. The healing of the anastomosis under such favorable conditions is a most important surgical principle. The postoperative course after these operations is uneventful—an indication of the absence of even mild grades of local peritonitis, and therefore of any degree of infection. Aseptic anastomosis is rendered possible by the fact that it is not necessary for the lumen of "defunctioned" colon to be at once reconstituted. In the case of rectosigmoid growths (a two stage operation) the distal colon is defunctioned and prepared for three weeks or a month. The growth is then resected, and the divided end of the sigmoid is sutured to that of the rectum. In a three-stage operation the anastomosis is not made after resection, as in the first method, but the severed rectum is sutured, the peritoneum is closed over it and the divided end of the sigmoid is implanted in the wound. Six months later, when the rectal stump is firmly covered with peritoneum, when the distal colon and the rectum are almost free from infection and when the patient free from the toxic effects of the cancer, is greatly improved in general health the sigmoid is connected to the rectum by making in the following way a "telescopic" anastomosis. The distal colon is mobilized and drawn through an opening that is made in the stump of the now peritoneum covered rectum and fixed in this position. The closed rectal cavity is laid widely open by cutting this sphincter. The intestinal end may be drawn through the peritoneum-covered abdominal wall on to its surface or it may be drawn through the peritoneum-covered rectum into a rectal space which is wide open externally. By the time the rectosigmoid junction is complete the sphincter has healed in order to make the patient again continent, it only remains to reconnect the colonic segments. In closing the disconnecting anus the enterotome is used and the spur is clamped for forty-eight hours and then cut through by further pressure. Five or six days later procaine hydrochloride is injected around the intestinal ends, which are then dissected from the skin and muscle and with the small openings in the abdominal wall, closed. Closure is prompt, as a rule.

Splint for Broken Clavicles—For fracture of the clavicle, with the patient seated on a chair, Henry molds a plaster girdle to grip the iliac crests. An assistant meanwhile passes a loop of ordinary bandage under the axilla on the injured side, then, standing behind the patient on another chair, he uses this loop to pull the shoulder steadily backward, outward and up as high as possible. The plaster, after encasing the lower abdomen, is then brought to the axilla of the injured side and surrounds the shoulder and upper third of the arm in such a way as to maintain the reduction obtained by the loop of bandage. A short sleeve enclosing the arm makes an angle of about 40 degrees with the side of the chest and is wide enough to allow axial rotation of the limb. The opposite shoulder is left free. Children require a wide bay in the jacket to allow room for meals. As soon as the plaster has set, the patient has painless use of the hand, wrist and elbow on the injured side. The plaster is removed on the twenty-first day. The patient at once has free use of the ipsilateral shoulder except for vertical elevation of the arm, but this is soon recovered when the slight stiffness due to the plaster cast has gone—often within an hour. The function of the rest of the limb is normal. The patient requires no further treatment and can

resume hard work within a week. The author has treated five cases of complete fracture of the middle third of the clavicle in this way since November 1934. A hand's breadth, measured from the axilla, is the best length for the short sleeve. Provided the plaster is properly based on the pelvis and care is taken to keep the shoulder high when it is drawn back, correction of the deformity will be almost as good as that which is said to reward those who lie on sandbags for three weeks.

Experiment with Rats on Human Dietary—For two and one-fourth years, Orr and his associates maintained a large colony of rats on a diet based on a dietary survey of a human population. Half of the rats were fed on the human survey diet or this diet with a small increase in milk, the other half on the same diet supplemented with additional milk and green food. Four generations of animals were reared from the same stock. The rats on the human diet with additional milk and green food were healthy in all respects so far as can be judged from rats on a stock diet and from the data of other workers. On the other hand in spite of an exactly similar environment and heredity, the animals without additional milk and green food showed (1) a slightly impaired reproductive capacity, (2) a markedly increased death rate due to increased susceptibility to an infection to which all rats were equally exposed, (3) a definitely slower rate of growth, (4) a lower hemoglobin content in the blood and (5) a clinically poorer condition as judged by behavior and state of the coat. The results are applicable to some extent to human beings. The authors suggest that a large section of the human population is still far from the optimal state of nutrition and that much could be done, by means of improved food supply, to raise the resistance to infection and to improve the physique of human beings.

Pseudo Schick Reaction and Toxoid Test of Moloney—Mitman observed 212 new members of the staff of the North Eastern Fever Hospital who were Schick and Moloney tested. The Schick-positive reactors were immunized with formol toxoid and post-Schick and Moloney tests were performed. He discerned that the intradermal toxoid test of Moloney or Zoeller corresponds exactly with the pseudo response in the Schick test. The pseudo response is as efficient as the Moloney response for detecting possible reactors to immunizing doses of toxoid and is a more accurate control of the Schick test. The Moloney test therefore appears redundant. A positive Moloney or pseudo reaction accurately indicates those who will react to immunization, but a negative Moloney or pseudo reaction is no guaranty that the subject will not react. The Moloney or pseudo reaction is evidence of bacterial hypersensitivity.

to specified products of the body of the diphtheria bacillus. Zoeller's theory that hypersensitiveness is a half-way stage between susceptibility and immunity is incorrect. Reactions usually, but not invariably, develop conjointly with immunity. Because of this parallelism, tests of hypersensitiveness give information as to the state of immunity. Bacterial hypersensitiveness bears a close relationship to antitoxic immunity. Immunity to diphtheria is something more than antitoxic immunity. If bacterial immunity exists, bacterial hypersensitiveness appears to have some place in immunity.

Rheumatoid Arthritis Believed to Be of Tuberculous Origin. Report of Two Cases. W. S. C. Copeman and R. D. Clay—p 1460

Hemolytic Streptococcus Fibrinolysis in Arthritis and Scarlet Fever—Stuart-Harris showed that the presence of resistance to fibrinolysis was related to hemolytic streptococcus infection, particularly if the resistance was of maximal degree, also that in streptococcal tonsillitis and pharyngitis resistance to fibrinolysis, if it occurred, was found in the second or third week after the onset of the infection. He has extended this work to include cases of chronic arthritis, rheumatic fever and scarlet fever. He has found that the blood of patients with rheumatoid arthritis is susceptible to streptococcal fibrinolysis. The blood of patients with rheumatic fever is resistant to fibrinolysis, particularly during the active stage of the disorder or after intercurrent streptococcal infection during convalescence from activity. The blood of patients with scarlet fever is resistant to fibrinolysis within three weeks from the onset in a minority of individuals and resistant in a majority of those patients with disorders of the heart or joints. Hemolytic streptococcus infection is considered to be related to rheumatic fever but not to rheumatoid arthritis. Hemolytic streptococcus infection of the respiratory tract in a rheumatic subject probably differs from a similar infection in a nonrheumatic subject.

Rheumatoid Arthritis—Copeman and Clay cite two cases of rheumatoid arthritis that suggested a tuberculous etiology and state that after full examination they decided to try the effect of a minute injection of tuberculin. The results, taken in conjunction with the other investigations reported, suggest that other cases of rheumatoid arthritis might prove to be of tuberculous origin if they were studied from this point of view. The two women responded to the injection of a minute dose of tuberculin by a general pyrexial reaction. A focal reaction also occurred in all the affected joints and in one case lasted for ten days. In addition to these reactions in the first case an area of heretofore undetected infiltration of the lung was rendered evident by the appearance of physical signs confirmed roentgenologically, while in the other case a cutaneous tubercle developed on the leg shortly after the injection. This ultimately healed. Most of the pathologic tests usually employed for the diagnosis of tuberculosis were positive in both cases. The authors believe that an unsuspected latent tuberculous focus was present in each case and was activated temporarily by the injection of tuberculin.

Angina Pectoris—Perry points out that three characteristics serve to differentiate anginal pain: the squeezing, constricting nature of the pain, its site and the relationship of the pain to physical or mental activity. A fourth feature, which is not constant, is the psychologic component of the symptoms, the sense of impending death. This feature may be described with pain other than anginal, for instance with the pain of gallbladder disease. The two conditions likely to be confused with angina are coronary thrombosis and the left inframammary pain or 'heartache' so frequently seen in debilitated anxious women. In coronary thrombosis the pain is identical in character, but if anything more severe than that of angina pectoris, and the patient may give a history of previous attacks of typical angina. Left inframammary pain affects women far more frequently than men and is typically situated under the left breast, or, as the patient usually says, "over the heart." It occurs characteristically, not during exertion but when the patient is resting at the end of a long and tiring day and it lasts for hours, long after the exertion has ceased. This symptom may occur in patients with normal or pathologic hearts but in no way affects the prognosis and must be carefully distinguished from angina pectoris, with which it has no connection. Angina pectoris occurs as a symptom in various diseases and the main pathologic processes with which it may be found are coronary sclerosis and atheroma, hyperpiesia, syphilitic aortitis, aortic incompetence due to rheumatic heart disease, syphilitic aortitis or bacterial endocarditis, severe anemias, particularly pernicious anemia and occasionally hyperthyroidism or paroxysmal tachycardia. In attempting to formulate a prognosis, the first thing to consider is the underlying pathologic condition. If the angina occurs as a symptom of cardiovascular syphilis, this in itself gives an average expectation of life of about five years. If the cause is a severe anemia that will respond to treatment, the outlook is correspondingly bright. In the majority of cases, however, no abnormal physical signs are found in the cardiovascular system with the possible exception of abnormalities in the electrocardiogram. Factors indicating a poor outlook are rapid progress in the frequency of the attacks and diminution in the amount of effort required to induce the pain. Such a state of affairs obviously indicates a rapidly progressive lesion. Another factor is the degree to which the patient can and will consent to limit his activities and attempt to live within his cardiac reserve. A poor prognosis is indicated by the discovery of any evidence of ventricular failure and also by the occurrence of attacks of paroxysmal nocturnal dyspnea (cardiac asthma). The treatment of the usual coronary form of angina consists in the relief and the prevention of attacks. Relief in the majority of cases rapidly follows cessation of the activity that induced the attack. This relief may be hastened by the administration of alcohol or the inhalation of amyl nitrite. If the pain continues despite rest and nitrites, it suggests an attack of coronary thrombosis, and it is undesirable to repeat a dose of amyl nitrite since in coronary thrombosis the essential factor is that the blood pressure should be kept as high as possible in order to encourage the opening up of anastomotic channels.

Oxidizing Ferments and Digestion—Matvieff investigated the quantities of oxydase, peroxydase and catalase contained in various raw vegetables and in various stages of digestion. The oxydase was determined by using 1 cc of a mixture consisting of 1 per cent naphthol, 0.75 per cent para phenylenediamine and 17 per cent sodium carbonate. This is dissolved in enough distilled water to make 10 cc and the substances are studied by soaking them with this solution. In the presence of oxydase the colors pass from violet to indigo blue. Peroxydase was determined by the Guici method. Catalase was found by adding hydrogen peroxide to the substance to be tested and obtaining water and oxygen in its presence. From the results of these studies the author concluded that the vegetable ferments play an important part in the economy of the organism. The presence of these ferments in the entire length of the intestinal tract must be important, though how is not yet clear. No action of these ferments on the pancreas could be demonstrated. These ferments are all heat labile, and it is therefore likely that the introduction of raw vegetables in the dietary may be a necessary part of the exchange metabolism.

*Treatment of Abscess and Gangrene of Lung by Intravenous Injections of Sodium Benzoate L Goldkorn—p 2094

Treatment of Lung Abscess and Gangrene by Sodium Benzoate—Immediately after the intravenous administration of a sufficient dose of sodium benzoate, a curious phenomenon is noticed according to Goldkorn. The patients notice an odor both sudden and agreeable. They also have a feeling of heat in the chest and head. This proves that the sodium benzoate has a definite affinity for the pulmonary tissue. Its elimination by the air passages is a symptom of saturation. As a result of 2,200 intravenous injections he feels that the optimum drying and antievacuation dose corresponds exactly to the dose that produces the aforementioned symptoms. The effect of any treatment on pulmonary abscess is difficult to evaluate and consequently only chronic and acute abscesses with progressive pulmonary destruction were used in evaluating the results of treatment. Two cases of chronic abscess and one of large, acute destructive abscess were treated in this manner and are

reported in detail. In five cases of bronchiectasis also a diminution in the quantity of sputum was observed. The smallest dose for pulmonary abscess is 20 cc of a 20 per cent solution each day. When symptoms of saturation are not produced by this dose, larger doses are indicated. The technic of injection is important. It must be made slowly and 20 cc should take five minutes. The purity of the preparation, which should be made fresh each time, is highly important. Daily injections are given. In the acute cases fifteen injections are usually enough, but in the chronic cases about thirty-six are generally necessary. They are continued until the clinical and roentgenologic signs have entirely disappeared.

Secondary Tuberculous Infiltrates in Children—Lichtenhahn points out that in the most frequent intrathoracic tuberculosis of children, namely, tuberculosis of the hilus glands, pulmonary infiltrations often develop, which cause rather acute symptoms. These infiltrations, adjacent to the diseased glands, are designated perifocal secondary infiltrations or epituberculous infiltrations. They often develop with great rapidity and may involve an entire pulmonary lobe. If they develop with sudden fever in children who had been apparently healthy before, they occasionally are mistaken for simple pneumonia, whereas, when it is known that hilus tuberculosis existed, they may be considered an acute and threatening dissemination of the tuberculous process. Although the author does not deny that tuberculosis of the hilus may occasionally take an unfavorable course, he says that roentgenoscopic control of the pneumonia-like infiltrations has revealed that they are usually harmless and disappear rapidly by complete resorption of the process, or by leaving behind traces of fibrous involution. The glandular focus, which is responsible for the secondary infiltration, often does not become visible until after the veil of exudation has been lifted by resorption. Thus the roentgenogram does not always disclose the tuberculous or epituberculous nature of the infiltrate, and other methods will be necessary for a differentiation from pneumonic or other infiltrates. The author describes the clinical aspects of several cases of temporary pulmonary infiltrates. One case, which at first was thought to be a secondary tuberculous infiltrate, later was found to be a pneumonic infiltrate, caused by a postpneumonic pulmonary abscess. The author discusses the elimination of bacilli and the problem of contagion in children with epituberculous infiltrates. He points out that formerly hilus tuberculosis was considered "closed", that is, the elimination of tubercle bacilli was denied. Now, however, it is conceded that tubercle bacilli may be excreted in all phases of intrathoracic tuberculosis. In children with tuberculosis of the hilus region the direct demonstration of tubercle bacilli in the sputum was usually impossible, but animal tests with pharyngeal mucus, gastric contents or feces disclosed tubercle bacilli in 55 per cent of the cases with infiltrations. From this the author concludes that the possibility of the elimination of bacilli and consequently a certain infectiousness should not be disregarded in cases of hilus tuberculosis with a tendency to successive febrile exacerbations.

Fatal Poisoning by Gold Preparations—Fatzer says that since the introduction of gold preparations, particularly in the treatment of pulmonary tuberculosis and of chronic rheumatism, undesirable complications (some with fatal outcome) have been reported repeatedly. After mentioning the symptoms of these complications the author reports two fatal cases of gold poisoning. She reaches the conclusion that toxic symptoms may develop after the use of any gold preparation and emphasizes the necessity of watching for the appearance of such symptoms in the course of gold therapy. At the slightest sign of a toxic effect the gold therapy should be interrupted. Typical agranulocytosis (in Schultz's meaning of that term) is rare after gold

therapy The toxic manifestations usually involve the entire hematopoietic system However, death may be caused also without hematemic changes It may result from hepatic impairment, enteritis or pulmonary abscess The author points out that the slow infiltrative pulmonary processes that have a tendency to abscess formation are especially frequent after gold therapy Some persons have a predisposition to gold poisoning This predisposition is more frequent in women than in men and in rheumatic than in tuberculous patients

The Adrenals in Amebiasis—Waldorp and Reforzo Membrives state that Addison's disease is often associated with hypoglobulia Addison described the disease as idiopathic anemia The presence of anemia however, is not constant in all cases of the disease, but it depends on the intensity of the adrenal disturbances or the presence of complications Amebiasis, especially the acute form, frequently causes grave and sometimes fatal alterations in the adrenals The type of adrenal insufficiency due to amebic hepatitis manifests itself by the appearance of a typical Addison syndrome associated with pigmentary hepatitis It seems to the authors that in these cases the adrenals react to the parasitic infestation of the liver by a mechanism of sensitization because of their relations to the liver in the functions of the metabolism of adrenal and hepatic pigments The authors report two cases of adrenal insufficiency of amebic origin with typical addisonian syndrome They call attention to the frequency with which a low arterial pressure and the presence of pernicious-like anemia are observed in patients with amebiasis They believe that these symptoms are due to adrenal insufficiency through the same mechanism that produces them in Addison's disease Adrenal insufficiency is also the cause of the changes in the blood picture as well as of the tendency of the temperature in those patients to remain below normal in spite of the presence of hepatitis and pernicious-like anemia

Diagnosis of Echinococcosis of the Bones—Ivanissevich and Introzzi wonder whether a diagnosis of osseous echinococcosis can be made early in the evolution of the infestation They report the case of a man, aged 55 in whom a tumor developed at the knee two years after occurrence of trauma The roentgenograms showed a deformed knee and the presence of round shadows A diagnosis of myeloplasmosis was made and a conservative operation, with fixation of the knee in extension, was advised At the beginning of the operation the surgeon found that it was a case of echinococcosis involving the femur, the tibia and the articular soft parts Amputation was performed The authors emphasize the importance of a biopsy which in their case would have clarified the diagnosis before the operation They conclude that echinococcosis of the bones has neither clinical nor roentgen pathognomonic characteristics except late in the evolution of the infestation The increase of the local temperature (Estlander's sign) does not prove the absence of echinococcosis Echinococcosis makes its appearance in the roentgenograms at the third period of evolution of the infestation that is when the macrovesicular hydatid geodes have already caused erosion and cavitation of the bones Microvesicular hydatids have the same coefficient of absorption of roentgen rays as that of the marrow bone This fact explains the reason why large areas of microvesicular infiltration fail to appear in the roentgenograms Roentgen round shadows indicate the presence of hydatid geodes They make their appearance in the roentgenograms at a time when the macroscopic lesions are still latent, but, even so the microvesicular infiltration is already extensive by this time That is why the authors point out the importance of devising new technics for roentgen examination of the bones to detect early microvesicular infiltration The conclusions of the authors have been verified by the observation of further cases, one of which is briefly reported

Significance of Inflammatory Reaction in Carcinoma Patients—Ebbhardt and Weinholtz report their studies on Kauffmann's inflammatory reaction in patients with carcinoma They found that the patient even in his last stages does not have as first assumed a reduced reaction capacity, but that his defense powers are especially mobilized and permit the development of an intense reaction If the blood elements fail to respond the mesenchymal cells may appear in the exudate Histologic examination reveals in these cases a considerable adventitious increase in round cells and histiocytes The frequently severe eosinophilia is a form of allergic reaction in the carcinoma patient In trying to evaluate the significance of these factors with regard to the organism's defense against carcinoma the authors point out that there is a zone of cellular reaction in which blood and cellular elements participate in various degrees The reaction of the leukocytes usually stands in a certain relationship to the manifestations of disintegration particularly to the superficial ulcerations The degree of mesenchymal reaction is extraordinarily changeable it may be rather high in mammary carcinomas, it is usually much lower in the superficial cancers of the mucous membrane and it may be considerable in the carcinomas of the skin which consists

of pavement epithelium. In the latter type the eosinophilia of the tissues plays a part. These processes have been regarded as a type of defense against the carcinoma, but the authors' investigations seem to indicate that the functioning of the defense powers of the tissues does not prevent the progressive development of the carcinoma and that a considerable portion of the reticulo endothelial system may have a normal or a supernormal reaction capacity while the organism succumbs to the further spread of the tumors. During this time of vigorous cellular reactions cachexia advances, the circulation declines and the patient dies as the result of this decline. Thus the process is practically the same as in many (not all) severe acute suppurating infections. Kauffmann's inflammatory reaction does not have the hoped for prognostic significance and the authors point out that the therapy of carcinoma cannot expect much aid from a modification of the reticulo-endothelial system.

Buerger's Form of Thrombo-Angitis Obliterans—Lindenbaum and Kapitzka show that Buerger's disease is a special form of thrombo angitis that is accompanied by a wandering phlebitis. In many cases this wandering phlebitis appears long before the arteries become involved. The intensity and the distribution of the venous process correspond to the severe changes in the arteries. The authors differentiate three stages of the disease process: (1) migrating phlebitis without or with only slight symptoms on the part of the arteries, (2) migrating phlebitis with noticeable arterial symptoms and (3) migrating phlebitis with progressive arterial thrombosis. The so-called obscure forms of migrating phlebitis without arterial symptoms must be regarded as the first stage of the disease. From the pathologic histologic aspect the venous process is a formation of thrombi. During the first phase there appears a new thrombus with inflammatory changes in the vascular wall, disintegration of the muscle fibers in the edematous perivascular cell tissue and formation of granuloma. During the second phase there is organization of the thrombus without granuloma formation which at first results in the complete obliteration of the vascular lumen and later leads to the formation of a dilated lumen of a type like a cavernous angioma. With regard to the etiology, the authors say that the hypothesis which assumes an allergic origin deserves attention because it is corroborated by the morphologic picture. They consider lumbar sympathectomy the best method of treatment for wandering phlebitis with thrombo angitis. The sympathectomy should be done during the second stage of the disease. If done at the right time it usually arrests the phlebotic process. The prognosis is extremely difficult in Buerger's disease, for there is always the possibility of a sudden outbreak of the thrombo-angitis with transition into gangrene.

*Movements of Thorax in Unilateral Pneumothorax Anita Bock—p 416

Life Duration of Tubercle Bacilli in Sputum Exposed to Sun—Zink made studies on highly infectious sputums that had been expectorated on the street and thus were exposed to sunlight. He found that tubercle bacilli that were capable of growth disappeared at the earliest after two hours and at the latest after five hours. Cultures that were made after four hours generally proved negative. Cooling and experiments at higher altitudes and under the ultraviolet lamp demonstrated that the bactericidal power of sunlight is chiefly due to its ultraviolet components. It was observed too that heat promotes the bactericidal effect. The author stresses that radiation in the high mountains owing to its greater intensity and its greater content in ultraviolet and short wave rays, has an especially great bactericidal power.

Movements of Thorax in Unilateral Pneumothorax—Bock points out that the therapeutic effect of pneumothorax is generally ascribed to collapse and immobilization of the lung.

Most authorities aim particularly at immobilization. However, it has also been pointed out that it is erroneous to identify collapse and immobilization, the two being not at all synonymous. A collapsed lung is not always immobilized and an immobilized lung is not necessarily collapsed. Pneumothorax treatment may produce considerable collapse and yet not effect immobilization. According to Schnippenkotter immobilization is present only in cases in which the ventilation of the lung is reached. Since a pneumothorax lung is always under the influence of the respiratory pressure fluctuations, immobilization is hardly possible. In unilateral pneumothorax there obtains as a rule only a smaller volume of the lung. Immobilization in unilateral pneumothorax would require either a limitation of the thoracic movements by the pneumothorax or, if the respiratory movements remain unchanged, the mediastinum would have to make respiratory movements. The author studied the thoracic movements of patients with pneumothorax by means of the method devised by Anthony and Hansen. These studies revealed that a unilateral pneumothorax influences the movements of the thoracic wall not at all or only slightly. Limitation of these movements was observed in only a few of the patients. However, it is possible that the lung is nevertheless immobilized as the result of the drawing of the mediastinum toward the healthy side during inspiration. It is extremely difficult to estimate the extent of the mobility of the mediastinum. The author believes that unilateral pneumothorax as a rule does not immobilize the entire collapsed lung, and she says that other observers, particularly Schnippenkotter, made a similar observation, the latter author ascribing the therapeutic effect of pneumothorax chiefly to collapse and not to immobilization. Bock thinks that, although immobilization of the entire pneumothorax lung is not likely, some parts of it may nevertheless become immobilized.

Influence of Coffee on Efficiency—Voigt studied the effect of ordinary and of decaffeinated coffee on the efficiency of soldiers whose service consisted largely in measuring distances from moving objects. The tests were made on ten men and covered a period of eight weeks. The various types of coffee were always given for five days and, in order to differentiate exactly the effects, two coffee-free days were intercalated between the five day periods. The efficiency that existed when no coffee was taken served as a basis of comparison for the efficiency under the influence of ordinary and of decaffeinated coffee. It was found that the drinking of ordinary coffee impaired the efficiency by 23 per cent, whereas the drinking of decaffeinated coffee either did not influence the efficiency or improved it somewhat.

Modern Therapy of Addison's Disease S Thaddea—p 76

*Therapy with Hormones of Female Gonads H O Neumann—p 79

*Genesis and Therapy of Extrasystoles J Pal—p 84

*Peculiar Disorders Resulting from Pulmonary Edema in Renal Insufficiency R Klima and H Rosegger—p 85

Therapy with Hormones of Female Gonads—Neumann shows that, in spite of the great advances in the experimental research on the sex hormones and in spite of the accomplishments of the chemists in preparing hormone extracts, the therapeutic utilization of these active substances is still rather limited. In view of the fact that the genital function is an extremely complicated interaction of many factors, which as yet is only partly understood, the author thinks that it cannot be expected that the therapeutic results will be perfect, the more so since many psychic factors also play a part. It is often extremely difficult to determine which particular factor has disrupted the interaction. Sometimes a treatment is surprisingly successful,

while at other times it fails. The author emphasizes that one should not overlook that the hormones of the gonads influence the entire organism and that the intensity of this action cannot be foretold.

Genesis and Therapy of Extrasystoles—Pal states that the genesis of extrasystole is not uniform, but that toxic, nervous, psychic and other factors may play a part. He pays especial attention to the extrasystoles that occur intermittently in persons without heart disease. After calling attention to his earlier studies on the detrimental effects of an elevated diaphragm on a diseased heart, particularly those caused by gastric tension resulting from pneumatosis and to studies on the significance of the inflated stomach in angina pectoris and on the incidence of extrasystoles in pneumatosis, he points out that pneumatosis is usually caused by insufficiency of the cardia by the aspiration of air into the stomach and by conditions of nervous excitation. The persons in whom the author made his observations were mostly healthy. He examined most of them after the noon meal, that is, at a time when the extrasystoles were most frequent. It is necessary to convince these patients that the annoying symptoms are of no particular importance in that they are caused by pneumatosis. The author was able to demonstrate thus readily after he had found that, particularly in men, the inflated stomach can be deflated by an eructation while the patient is lying on his left side. In women without heart disease extrasystoles are rarer than in men. However, the author does not imply that an elevation of the diaphragm by an inflation of the dome of the stomach is always present in these extrasystoles for he points out that the elevation of the diaphragm may be produced also by the intestine. He observed an inflation of the transverse colon particularly in women with the so-called spastic type of constipation. The extrasystoles occurring in these women could be counteracted by overcoming the intestinal disorder. To be sure the appearance of the extrasystoles is not entirely explained by the elevation of the diaphragm, but the heart also plays a part. Observations in the course of postural changes, which involved changes in the position of the heart but not of the diaphragm, and experiments on dogs indicated that mechanical irritations of the pericardium, which are produced by the abdominal viscera are the cause of the described extrasystoles. In discussing the treatment of these extrasystoles, the author calls attention to formerly suggested measures regarding the prevention and treatment of pneumatosis and heartburn and also stresses the importance of the prompt evacuation of the stomach and of the intestine. Medicaments for the heart are unnecessary in patients without heart disease.

Peculiar Forms of Pulmonary Edema in Course of Severe Renal Disorders—Klima and Rosegger report the clinical histories of three patients and state that among eighty patients with chronic nephritis, nephrosclerosis and uremia they found twenty cases in which roentgenoscopy disclosed pulmonary foci that disappeared in response to renal and cardiac treatment. The majority of these patients had temporary, usually nocturnal, attacks of dyspnea and nearly all had increased blood pressure, an abnormally high rest nitrogen and nephritic renal changes. On the basis of the clinical aspects and of the physical examination, inflammatory pulmonary foci could be excluded; however the roentgenologic differentiation from inflammatory processes of the lung was considerably more difficult and the roentgenologic diagnosis often was given as lobar pneumonic foci of infiltration. The authors mention the following aspects as the factors that differentiate these nephrogenic pulmonary edemas from the cardiac type: 1 Attacks of dyspnea which frequently occur during the night and may be accompanied by coughing and by the appearance of foam or pink sputum. 2 Hemoptysis which generally is not severe. 3 Various areas of dullness, which however, readily escape detection and crepitation. The latter signs are not restricted to the lower part of the lung and they may even be entirely missing in the lower part. 4 Transience of these symptoms. The author thinks that the localization of the edema, namely, the fact that it leaves the lower portion of the lung free, is the factor which militates most clearly against a cardiac origin. He reviews the roentgenologic differences between cardiac stasis of the lung and the nephrogenic pulmonary edemas, which were described by Zdravsky.

Clinical Aspects of Hypertrophy of Prostate R Paschalis—p 113

Crampus Neurosis and Gout—Vogl directs attention to a type of muscular cramps designated by Wernicke, who first described it as crampus neurosis. The author considers this term not quite suitable and shows that the earlier investigations on this disorder did not clarify its etiology. Studies in recent years, however, particularly those conducted by Wilder, disclosed a hyperuricemia in patients with this type of muscular cramps. Further investigations by Wilder and studies conducted by the author himself revealed that a metabolic disturbance of the type of gouty diathesis predisposes to painful muscular cramps and that these cramps have no connection with a neurosis. The author stresses that the appearance of muscular cramps is a frequent and even a typical occurrence in true gout. The appearance of the cramps often precedes the development of true gout by many years. Thus, if in case of a doubtful diagnosis the anamnesis reveals muscular cramps the disorder is probably gout. The author suggests that Wernicke's term crampus neurosis should be replaced by the more suitable term "uratic crampus diathesis" and the disorder should be classified with the group of disturbances of the uric acid metabolism. For the treatment of uratic crampus diathesis he recommends the same dietetic and medicinal measures that are employed in gout. Injections of calcium are also helpful.

Sulfur Therapy in Nurslings—According to Oppenheim and Fantl, recent reports indicate that the use of sulfur pastes in nurslings with scabies has resulted in severe disorders and even in death. They concede however, that nearly all remedies used in the treatment of scabies (Peru balsam, tar, betanaphthol and so on) are likely to produce toxic effects in nurslings and that sulfur is generally considered the least toxic of the parasiticides. The authors state that an ointment which contains sulfur has been used by them regularly in nurslings with skin disorders and particularly in those with scabies. However, because of the practical importance of the toxicity of sulfur they decided to conduct animal experiments. On the basis of these tests they reach the conclusion that the animal organism tolerates considerable amounts of sulfur and they do not agree with Basch, who had decided that scabies in nurslings should not be treated with sulfur preparations but with other substances. They concede that sulfur therapy may result in undesirable complications, but they point out that there is probably no substance which does not eventually do that. They think that, even though sulfur may not be an ideal substance for the treatment of scabies in nurslings, it nevertheless has its advantages and it causes serious complications only in rare instances. They know of no antiscabetic remedy that is entirely harmless.

- *Perforation of Gastric Duodenal Ulcer One Thousand Cases S S Yudin—p 25
Importance of X Rays in Diagnosis of Perforated Ulcers S V Ivanova Podobed—p 47
Study of Etiology of Acute Perforations of Peptic Ulcer D A Arapov and V F Grosse—p 57
Principal Stages in Development of Problem of Transfusion of Cadaver Blood M G Skudina—p 69
Biochemical Changes of Cadaver Blood M G Skudina R E Ginzburg and A V Ruskov—p 78

Perforation of Gastric Duodenal Ulcer—Yudin states that the incidence of ulcer disease in women in his general material was 10 per cent and that the incidence of perforation in women was less than 2 per cent. Thus among 1014 cases of perforation eighteen were in women. Only two of these were users of tobacco. The curve of incidence increased regularly during the second half of the winter to reach its highest point by the end of the spring after which it exhibited a decline and reached its lowest point in August. The author speculates on the seasonal increase in perforations by supposing that the decreased use of vegetables and of fruit brings about a state of avitaminosis which renders the tissues less resistant.

to the ulcerative process. A considerable number of perforations took place after the big meal of the day, suggesting that overdistention of the stomach acts as a direct etiologic factor. While an adherent of Rosenow's theory of infection as the determining factor in the causation of ulceration as well as in the act of perforation, the author states that gastritis was frequently absent in his cases of perforation. The existence of grip or tonsillitis did not appear to be the determining etiologic factor. Besides the pathognomonic signs of perforation the author emphasizes that the pulse is either normal or slowed and that vomiting is unusual. The phrenic symptoms, or radiation of pain in the shoulder, is helpful and is suggestive of perforation of a duodenal ulcer if the radiation of pain is in the right arm or shoulder, and of a gastric ulcer if the radiation is in the left arm or shoulder. Free gas in the peritoneal cavity is pathognomonic and was demonstrated roentgenologically in 80 per cent. In the treatment of perforation, opinions differ as to whether to limit the operative intervention to the saving of the patient's life or to direct it to the cure of the disease at the same time. Necropsies in cases in which simple closure of the perforation was practiced not infrequently revealed fresh ulceration along the suture line. These ulcers in some of the cases led to fresh perforations. The author believes that the virulent infection present was responsible for the untoward result. Among the advantages of the more radical treatment the author states that gastric resection restores the motor and evacuating function of the stomach, removes the ulcer and the ulcer bearing area, removes the infected area, and results in a maximal lowering of acidity. Organic disease of the heart or of the vascular system, obesity, diabetes, active tuberculosis or nephritis contraindicates radical therapy. The general condition of the patient is a safer indication than the number of hours elapsed since the perforation. Age is the most important factor to consider. Resection is advisable in the early cases only in patients past 45 years. Resections should be performed by experienced surgeons with properly trained assistants. The author prefers spinal anesthesia. The abdomen is always closed without drainage. The mortality rate in a group of 673 partial gastric resections performed in the course of six years for perforation was 98 per cent. In operating the author prefers the first method of Billroth. His mortality rate in another series of 331 resections performed during 1933 and 1934 was 78 per cent. The mortality rate for 121 resections performed by him in 1935 was still further lowered to 66 per cent.

Preventive Treatment Against Thrombosis and Phlebitis—To provide a means of effective exercise as early as possible after operation, Dalsgaard has devised an apparatus to be fastened to the foot of the bed, which applies the principle of the bicycle and consists of an axis and pedals, the latter with shoes attached to hold the patient's feet. He regards the active muscular work of the lower extremities in pedaling the "bed bicycle" and the pressure rhythmically exerted by the bottoms of the feet as most important in prophylaxis against thrombosis and phlebitis, since it increases the rapidity of the venous circulation and thus hinders chemical changes in the blood.

*Origin, Symptoms and Treatment of Pulmonary Emphysema in New Light H. Heckscher—p. 57

Gymnastic Exercise Applied in Treatment of Patients with Pulmonary Emphysema Agnete Bertram—p. 74

Investigations on Serum Amylase in Chronic Alcoholics Preliminary Report H. Christiansen—p. 79

Origin, Symptoms and Treatment of Pulmonary Emphysema in New Light—Heckscher defines pulmonary emphysema as a disease in which the objective cardinal symptom is a stethoscopically demonstrable extension of the boundaries of both lungs when the patient is examined in the natural standing position the thorax and lungs being in their habitual position. His 181 cases in which treatment was administered during the last four years represent forms from the mildest with purely functional disturbances to older chronic cases with

organic changes in lungs, bronchi and circulatory organs. Twelve cases are described. The condition is almost always due to functional disturbances. Treatment must be directed to the causative factor or factors, such as improper posture ("soldier position," scoliosis, kyphosis, kyphoscoliosis, lordotic phthisic habitus), adiposity, disorders of the mucous membranes of the respiratory passages, neuroses, heart disease and too heavy physical labor. In most cases the treatment must be combined with gymnastic exercises designed to correct the defects in the posture of the back and thorax and to establish abdominal respiration, leading to normal respiratory rate, reduction of the emphysema and disappearance of the subjective symptoms. Individualization is necessary in the exercises.

*Remote Effects of Removal of Normal Spleen in Man Contribution to Pathophysiology of Human Spleen E. Ask-Upmark—p. 197

Effects of Removal of Normal Spleen in Man—Among Ask-Upmark's 100 cases from Sweden in which the normal spleen had been removed (in ninety-nine cases owing to traumatic injury and in one case to movable spleen), from one to twenty-seven years earlier, and ninety-four cases from the literature, eleven deaths had occurred, five of them from pulmonary tuberculosis. No increased susceptibility to infections or to malignant tumors was seen in his material, but he emphasizes that only from 15 to 18 per cent had reached the cancer age on after-examination. A tendency to rapid exhaustion was not infrequently present. Various disorders in the digestive tract were noted in about 10 per cent, likewise disturbances in the nervous system and metabolic activities, and changes in body weight. In most cases the morbidity was the same as in the average person. The author thinks that persons whose normal spleen was removed a year earlier should be accepted for insurance on the usual terms, and, if not accepted, should be examined at least once yearly in the expectation of an eventual bodily adjustment to the splenectomy. Anatomically, physiologically and clinically his investigations indicate that the spleen, while not necessary to life, should be removed only on vital indication.

*Cystic Mastopathy and Its Treatment with Estrin E. Dahl Iversen—p. 1151

*Treatment of Crises in Addison's Disease P. Schultzer—p. 1153

Cystic Mastopathy and Its Treatment with Estrogenic Substance—In younger patients Dahl-Iversen advises conservative treatment and considers surgical treatment only when conservative treatment is without effect and the patient's complaints or a suggestive change in the clinical picture indicates operation. Support of the affected breast without compression is recommended, together with oral administration of from 2,000 to 3,000 mouse units of estrogenic substance daily or intragluteal administration of from 10,000 to 20,000 mouse units weekly for at least half a year then continued at intervals to control the symptoms. The author says that conservative treatment should also be tried in women past the middle forties, but here aggravation locally and generally may occur under treatment with estrogenic substance. In all patients and particularly in the older patients conservative treatment calls for close and continued observation. In the majority of cases with a clinically localized process partial extirpation is followed by freedom from symptoms for a long period of years continued observation is necessary. In cases with diffuse changes, ablation of the breast is the rational method possibly with preservation of the skin areola and papilla. If the microscopic examination after partial or total excision shows malignant changes, a second radical operation is indicated.

Treatment of Crises in Addison's Disease—Schultzer finds that treatment with adrenal cortex extract alone or in combination with sodium chloride has an excellent effect in acute insufficiency of Addison's disease. The improvement in the general condition is reflected in the patient's appearance. Reduction in blood urea values affords a numerical expression of the improvement. No certain information is obtained from the blood chloride
